Mr. RIEVE. There are no figures in the textile industry so that you can make an over-all cost. The cost varies so much, depending upon the fabric, that you can't arrive at that kind of figure.

Acting Chairman WILLIAMS. I understand that there are varying fabrics, but I was wondering whether there are figures available which would show the over-all cost of the entire industry in 1929 as compared with 1939.

Mr. RIEVE. There are no such figures available. I haven't seen any. I don't think the Department of Labor ever prepared those.

Mr. PIKE. You find it difficult to average out between a cotton sheet and a silk stocking?

Dr. LUBIN. You also have the other factor, that the same plant may have two fabrics, upon one of which they are making money, and the other on which they are losing money.

Mr. RIEVE. If you go a little further, you can't compare a cotton sheet with a carpet. You can get the figure for the carpet industry or the cotton-textile industry, but you can't lump the textile industry together and get an over-all cost that way.

Acting Chairman WILLIAMS. Have you got it, then, for the different branches of the industry?

Mr. RIEVE. Yes; we have it for the different branches of the industry.

Acting Chairman WILLIAMS. All right, what is it?

Mr. RIEVE. Man-hour output in the cotton-textile industry—

Acting Chairman WILLIAMS (interposing). I am talking about cost.

Mr. RIEVE. Oh, no, we don't have that.

Acting Chairman WILLIAMS. You seem to think you can get that.

Mr. RIEVE. That probably could be got.

Acting Chairman WILLIAMS. But you haven't it, and that's that.

Dr. LUBIN. I might say that the Federal Trade Commission has some figures on earnings of the various branches of the industry for a series of years starting in 1933, I think. I think they run up to 1937 or '38.

Mr. BARKIN. To '36.

Acting Chairman WILLIAMS. To what extent have you applied through your bargaining agency with industry, some kind of separation allowance in the textile industry?

Mr. RIEVE. To a very, very limited extent. We have it with a very few companies. I think I stated in my presentation that we only have it in three companies. I brought it in as an indication that through legislative methods, or through other means, that type of arrangement ought to be explored further and brought about, to thus cushion—

Acting Chairman WILLIAMS (interposing). What kind of legislative arrangement do you think could be made about that?

Mr. RIEVE. There are several things that could be done. Something could be worked out. As I say, that would have to be studied. As an example, we have social security, by which employers are taxed and workers are taxed, and when a worker reaches 65 years of age he is entitled to unemployment compensation. Why couldn't industry be taxed in the same manner, to set up a fund to pay workers as they are displaced by technological changes? That would be one way. I don't say that it is the proper way. I am just indicating that it is one way to do it. There might be many other ways.

Mr. PIKE. You said, Mr. Rieve, that you had not much trouble in dealing with the prosperous units of this industry, and I take it that means pretty much the synthetic fiber end. Now, I think it is notorious that in the cotton mills there are a great many nonprosperous members, to put it mildly. We have had a great many large mills go out of business and disappear in the last several years, and in circumstances like that it almost always means there are other mills on the edge who just don't have the capital to do things. There has been technological displacement of dollars as well as men. Sometimes that can be painful to the owners of those dollars. But that does make a real problem there.

Mr. RIEVE. That is correct. That is why I stated that if we were to adopt a dismissal wage principle, it must be adopted through governmental agencies and not through individual mills, because if a marginal mill wanted to enter into an agreement with a union that if technological change came they would pay a dismissal wage, I don't know whether I would accept the agreement, because I don't think they could fulfill it when the time came.

Mr. PIKE. That is one of the things I am driving at. A fairly good indication is the price of mill shares, and you see very frequently where the total selling price of the mill, multiplying the number of shares by the price of the share, is less than their net current assets on hand, allowing nothing at all for mills and ma-

chinery. You remember probably a dozen of those in the last several years, so that on the face of it it would be profitable for the mill to close up shop, liquidate its current assets and quit, and one might think a mill management might always have that under consideration, and a new consideration might turn their decision either way. It is a very difficult situation for all concerned. I think you recognize that. And with this very competitive industry, one person who is profitable can do it, this other fellow who is on the ragged edge won't or can't do it unless he is compelled to.

Mr. RIEVE. It cannot be done voluntarily. It has to be done by action of some governmental agency.

Acting Chairman WILLIAMS. I noticed you discussed to some extent the question of skilled labor being supplanted by unskilled labor. Is that the situation generally? Is that the trend?

DIVISION OF LABOR IN TEXTILE PLANTS

Mr. RIEVE. The trend is to separate the skilled worker in the textile mills. In days gone by he performed various tasks. It didn't necessarily follow that every minute of his time was consumed on a skilled task. Probably the bulk of his time was consumed on skilled tasks, but he was also doing some unskilled work. The tendency now is to separate that. As an illustration let me take a weave shift. A weaver in days gone by operated, say, 4 or 5 looms, and he would tie the cloth on the bobbins, yarn, and all these operations. Today he is not doing that. He is only weaving, and they have battery hands who do the other tasks, and the result is that the weaver, instead of taking care of 4 or 5 looms, is taking care of 50 or 60, and, in one or two instances we know, of 120 looms.

Acting Chairman WILLIAMS. Let me ask you this. Has the technological improvement in the textile industry changed the nature and character of the skilled workman to such an extent that a man who formerly would be considered a skilled workman in his particular line, by reason of these improvements, was not fit, and didn't have the skill to carry on under the improvements, and in that way displaced many of the skilled workers?

Mr. RIEVE. That is correct, very much so.

It necessarily follows, as I explained in the weaving shed, that there were many improvements on that loom. The weaver was able to take care of more looms because he confined his activities entirely to skill, and unskilled people came in and did the other work. That means that other skilled weavers were laid off.

Now, you have other technological changes, such as in the woolen industry, where you still have the old mule spinning system that is being replaced by a new system where the spinner, a skilled operator is being displaced by a woman.

Acting Chairman WILLIAMS. I don't believe that is the idea that I had, as I understand you. We have had evidence here, for instance in the steel industry, of the old hand roller mill skills. When they introduced the strip-mill process, while the old worker, the former employee, was skilled in his line of work, the inauguration of the new machine made him entirely an unskilled worker so far as managing that machine was concerned, and he was out entirely. He could not continue at all, because while he was skilled under the original process

when it was supplanted by an entirely new process his skill was gone, and he was out.

Mr. RIEVE. Well, that is true in some instances, as in the instance that I described between the mule spinner and the ring spinner. A mule-spinner operation was an operation that was entirely operated by males. Now a new operation came in. It is also called spinning, but that operation is entirely different in character from the other one, much simpler, and the result of it is that women are employed in that operation, and the mule spinner is out of a job.

Now, I wouldn't take the position that the mule spinner could not become a ring spinner. Probably he could. I would question, however, whether he could become as efficient as a girl can be on that job. So he is entirely out.

Dr. LUBIN. Mr. Rieve, as you went through your material I was impressed by the fact that there were four factors operating in the industry, and I wonder if we could stop them. In the first place, we are creating unemployment by mills moving away. As you say, communities make offers of free taxes and subsidize the cost of building the mills, and mills move away from a certain part of the country and go into a new section. I take it that that movement has nothing to do, or little to do, with technological change. It is a question of costs; you can get cheaper labor some place else, somebody puts up the mill.

Mr. RIEVE. I think it is somewhat accelerated by technological changes.

Dr. LUBIN. But the movement itself could take place without any technological changes.

Mr. RIEVE. Yes; it could.

Dr. LUBIN. Secondly, speed-up. In other words, there is evidence to the effect that certain mills have increased productivity without changing their machinery, but by speeding up the operation.

Mr. RIEVE. That is right.

Dr. LUBIN. And, thirdly, you have what might be considered technological change, in the sense of better organization of the plant, which eliminates certain wasteful practices, and, finally, you have machinery. Which of these are the most important, and which can we expect to play the greatest part in the immediate future? In other words, can we break those four factors down and measure the extent to which each is responsible for unemployment?

Mr. RIEVE. Well, of course, any prediction for the future would be a guess. I would say that probably the greatest amount of unemployment is caused by the physical layout of the mill, improved operations through rearrangement of processes, and so forth, secondly, probably by machines, unless something new and revolutionary happens that is not now in the making.

Dr. LUBIN. There have been no revolutionary changes in the industry during the last 10 years?

Mr. RIEVE. No; new things are coming in, but I wouldn't call them revolutionary. They are speedier, and so forth.

Dr. LUBIN. Would you say that the bulk of this—

Mr. RIEVE (interposing). Only in the rayon industry. When you talk about the synthetic rayon industry—

Dr. LUBIN. That is an entirely different situation. Would you still think that as far as cotton and wool are concerned that machinery would be the second factor?

Mr. RIEVE. In wool, especially in wool.

Dr. LUBIN. What effect is the nylon development going to have upon the hosiery industry; that is, employment in the manufacture of silk hosiery?

Mr. RIEVE. First I think we will have to find out what nylon really will be. There has been considerable in the public press. I do not think that it will have an effect on the hosiery industry as such, but it will have on the throwing industry, the silk throwing industry; all that equipment will become obsolete and will have to be scrapped. You cannot use silk throwing equipment for synthetic yarns. The hosiery machine can be used for nylon. It is claimed that the nylon will wear longer. If that is true, probably to that extent sales will be curtailed, but outside of that I don't anticipate any difficulty in that industry as a result of nylon development.

Dr. LUBIN. Following up this whole question of displacement, you state in your brief that the number of spindles has been very markedly cut down and yet the output of the industry has gone up. I take it that increased output is the result of using synthetic yarns in mixture with cotton.

Mr. RIEVE. That is one, and also as the result of shifts; the remaining spindles are used two and three shifts as against one shift up to about 7 or 8 years ago.

Dr. LUBIN. But that would increase the man-hours of employment proportionately, wouldn't it?

Mr. RIEVE. No; but it would the spindle hours.

Dr. LUBIN. It is a question of spindle-hour increase?

Mr. RIEVE. And there is more productivity in spinning equipment. The new spinning equipment is much more productive. As a matter of fact, the only appreciable technological changes that the cotton industry made in the last few years were in the spinning departments.

Mr. CHANTLAND. Is there a difference of pay rate on the different shifts?

Mr. RIEVE. No. In the bulk of the cotton industry the pay rate is too little whatever it is.

Mr. CHANTLAND. Whether it is the night shift or day shift?

Mr. RIEVE. Whether it is the night shift or day shift. Some individual concerns may pay slightly more on the third shift, but it is not a factor in the industry.

Mr. PIKE. You mentioned in your statement the fatigue factor, which I presume still shows up in several places in the textile industry. Of course, that must be getting reduced pretty well to a minimum with the short hours, isn't it, now, or do you still find that is a considerable factor?

Mr. RIEVE. Oh, it is a factor, because no man or woman can work, even assuming that there is a lunch period, on an 8-hour employment day 4 hours without some rest period. The fatigue question is not as important an item on an 8-hour workday as it would be on a 10- or 12-hour day, but it is still a factor.

Mr. PIKE. Most of that work, or a great deal of it, requires close mental attention rather than hard physical work, doesn't it?

Mr. RIEVE. That is right; it is tedious work.

Mr. PIKE. Waiting for a break?

Mr. RIEVE. Most of it is walking, these days. In the weaving room the man who is patrolling just keeps on patrolling. It is so

mechanized that he gets tired from walking; at least, he walks probably as much as a policeman on a beat. The only difference is the policeman walks in fresh air while he is walking inside a factory.

Mr. PIKE. Sometimes the policeman would be willing to swap, I think.

Mr. RIEVE. I suppose, sometimes.

Acting Chairman WILLIAMS. Did I understand you to say there were 1,250,000 employed?

Mr. RIEVE. That is right, in all the divisions of the textile industry.

Acting Chairman WILLIAMS. How is that divided, approximately, between men and women?

Mr. RIEVE. I don't have the figures. It would be just a guess as far as men and women are concerned. I would say about 50-50.

Acting Chairman WILLIAMS. Has there been a tendency to employ one or the other more in the last 10 years?

Mr. RIEVE. Yes; the tendency has been right along in the direction of more women.

Mr. PIKE. What percentage are organized of that 1,250,000?

Mr. RIEVE. We have, as I stated, 350,000.

Mr. PIKE. And the total amount organized wouldn't be very much in excess of that? Would it run 450,000?

Mr. RIEVE. I wouldn't even claim that. I don't think it necessarily follows because we have 350,000 workers covered by collective bargaining contracts that we claim we have that big a membership; because we act as the sole collective bargaining agency it doesn't necessarily follow that all of the people are members of the union.

Mr. PIKE. Would you say it would be more than a quarter and less than a half?

Mr. RIEVE. Oh, it is less than half; I wouldn't claim more than a quarter.

Dr. ANDERSON. Mr. Rieve, a quarter of the workers of the industry are fully covered by agreements?

Mr. RIEVE. Yes; about 350,000 covered by agreements.

EFFECT OF UNIONIZATION ON PRODUCTION COSTS

Dr. ANDERSON. What are the possibilities of price competition between union and nonunion plants in an industry so keenly competitive, and where only a quarter of the workers are covered by agreements?

Mr. RIEVE. I think the possibilities are very good because we are not foolish enough, even though we have the shop organized, to make exorbitant demands of the employer if his competitors are not organized.

Dr. ANDERSON. In other words, the advantages that the unorganized plants have in regard to technological change are not so great but that you can compete with them?

Mr. RIEVE. That is right, that is right. The union shops, just as well as the nonunion shops, are putting in technological improvements if they have the money to do it.

Dr. ANDERSON. How far are technological advance, and the other problems of this rather sick textile industry, related to market expansion itself, to increased sale of goods?

Mr. RIEVE. Well, I don't know. The sale of textiles has been mounting for the last few years. Where the limit of it is I don't know. I suppose that technological improvements, mill lay-outs, and so forth, have had a tendency toward broadening the market. I suppose that because of the tendency to sell cheaper, more people are buying textiles, but to what extent I cannot say.

Dr. ANDERSON. Do you think that is the hope for the solution of the problem—a greatly expanded consuming market which will absorb the workers not now used?

Mr. RIEVE. I think that is one way of approaching the problem, if we devise some means of giving the consumer the purchasing power necessary to absorb these goods, but I wouldn't say that that alone will solve the whole problem.

Dr. ANDERSON. Given present market trends, and the present 1,250,000 workers in the field, is there any prospect that the textile industry will absorb the workers not now employed?

Mr. RIEVE. No, not in my opinion, unless the European war continues and we start to buy textiles in this country. Not under normal processes, no.

Dr. ANDERSON. Is the problem of child labor still a serious problem in the textile field?

Mr. RIEVE. Not since the wage-and-hour law passed. The wage-and-hour law has in itself a provision that no children under 16 years of age be employed.

Dr. ANDERSON. Was there a shift then to children above 16?

Mr. RIEVE. Yes.

Dr. ANDERSON. So that you did accent that problem?

Mr. RIEVE. Yes.

Dr. ANDERSON. What is the reason for the increased use of these youngsters from 16, say, to 20? Is it linked with technology?

Mr. RIEVE. No; I would say it was linked with wages more than technology.

Dr. ANDERSON. But the industry is such that youngsters of those ages can perform the necessary operations?

Mr. RIEVE. Yes; some operations. Of course, when a new technological process comes in, an employer would rather teach youngsters that process than to retrain older people, for two reasons. It has to be admitted, I think, that a young person, never knowing an operation, can probably learn given operation much quicker than an older person who has been trained in another operation, because the older person has to be untrained, and the new one does not. Secondly, the hope is that after that younger person acquires the necessary skills or routines the employer will have a longer period of use out of that person than out of an older one. Therefore, in new processes the employer tends to train new people for these processes rather than retain the older ones.

Mr. CHANTLAND. I thought you answered the chairman when you were talking about the tendency toward unskilled workers, by telling him that the technological situation by which a man could supervise as many as 100 or more machines let them hire these boys that Dr. Anderson was inquiring about in unskilled positions. That is technology, isn't it?

Mr. RIEVE. Yes.

Mr. CHANTLAND. Which position do you want to take? I thought your answer to Dr. Anderson was that technology had nothing to do with hiring these 16- or 20-year-old boys.

Mr. RIEVE. I don't think that either my answer to the Chair or to Mr. Anderson is contradictory. What I said about these weavers who control as high as 100 looms is that that is not a changed technology.

Mr. CHANTLAND. Isn't it?

Mr. RIEVE. No; that is a changed process; they use their experienced men but fewer of them. They don't have to retrain these people.

Mr. CHANTLAND. You mean that it isn't technology that gives a man the power to supervise so many as against so few?

Mr. RIEVE. It is not technology in the sense of some new, radical, revolutionary invention that comes in. It is only technology to the extent that a separation took place between the skilled operations and the unskilled operations.

Mr. CHANTLAND. Apparently we don't agree on where technology begins and leaves off.

Mr. RIEVE. We may not talk the same language.

Mr. CHANTLAND. May I ask one more question if I am not interrupting? You said "customarily he has taken to the only weapon of protest that he has—the strike." How can there be any reasonable probability of improving the position of the laborer by a strike in a decreasing labor market such as you described?

Mr. RIEVE. I did not say that that was the right thing to do. I gave a statement of fact, that that is what happened. It wasn't the proper way to approach the problem. It did not improve the welfare of the textile worker.

Dr. LUBIN. Mr. Rieve, you mentioned something about speed-up, and you probably are still very conscious of the terminology that was used in the early 1930's about the load. What has the union done to handle that problem? How does the union take care of these tendencies toward speed-up?

Mr. RIEVE. I don't know, Dr. Lubin, that I entirely follow your question.

Dr. LUBIN. There was a tremendous amount of discussion about the load that each worker had to carry in the textile industry in the early 1930's. The matter of fact is that you state one of the reasons for the strike in 1934 was that the speed-up system had been put in effect as the result of the shortening of hours.

Mr. RIEVE. We are trying to make the worker think a little different from what he had formerly been thinking. I think to a very limited extent we are succeeding. We do not subscribe to the theory that as a result of a technological improvement the remaining worker necessarily works harder; he may, but it does not necessarily follow that he does. We are rather trying to get the worker to forget about this type of terminology and this type of psychology and try to think in terms of how he is going to protect the job for the people that are being replaced. I think we are succeeding remarkably well in that direction. That is about all that has been done in that. Wherever we have contractual relations, when a work assignment is put in effect, we send our own engineers, our own time-study men, in

to find out whether it is a regular speed-up, or whether something in the processes is being changed.

Dr. LUBIN. There is one thing that interested me about your testimony that raises a question as to whether this is a permanent phenomenon, or whether it is temporary. After all, the textile industry is a very old industry. It is an industry which has been criticized very frequently because of the fact that it has been old-fashioned in the sense that there have been many, many mills in this country that are still operating with equipment that was installed in the nineties. In fact, I think an engineering study made some years ago showed a tremendous number of firms with equipment more than 30 years old. How far has the competitive situation that has arisen in recent years forced these mills to be modernized? Once that modernization is completed will that mean that the rate at which displacement takes place will tend to fall?

Mr. RIEVE. I think that the casualties in one form or another in these mills that you describe have been terrific lately. I think that probably the cotton-textile industry by and large today is modernizing itself. There probably are some mills that have this 30-year-old equipment, but they probably are very few and far between, because the competitive situation would not permit that to continue.

Mr. PIKE. They, in general, have been forced out of business rather than modernized?

Mr. RIEVE. Well, some have had to put in new capital and modernize, and others have had to pass out of existence. I would rather say that the number that put in new capital is probably less than the number that passed out of existence.

Dr. LUBIN. Does that mean, then, that the rate of change will tend to decline because these mills have done most of their modernizing?

Mr. RIEVE. No; I wouldn't say so, Dr. Lubin. In the cotton-textile industry today the equipment is not so much being modernized as the mill is being systematized and more and better fibers are being used. Put it this way: When they made silk the weaver operated probably 4 or 6 looms; in synthetic yarn the operator is operating as high as 25 and 30 in many instances, partly because of improvement in the loom, but also in great part because synthetic yarn runs better, there are fewer breaks, and so on, than cotton. This type of change is more predominant in the cotton-textile industry today than the real mechanical changes.

PROSPECTS FOR INCREASED EMPLOYMENT

Dr. ANDERSON. Your industry is particularly subject to it. We would like your comment on this subject of ghost towns, to which your industry is particularly subject. You say a cotton-textile plant is frequently the single industry in a town. What is the prospect of ghost towns in the future in your industry?

Mr. RIEVE. The prospect in the textile industry is an increased number of ghost towns.

Dr. ANDERSON. Do you have any figures or any indication of what that looks like?

Mr. RIEVE. Well, I don't have exact figures. The American Woolen Co., for example, at one time had about 55 mills scattered throughout the country, most of them in very small communities, and now has

about 22 or 23, or something like that. They announced last week that they were closing up a mill in a small one-mill town in New Hampshire. That means that that community is going to be another ghost town. The prospects are increasing in that direction.

Dr. ANDERSON. Do you, as the union representative, have any suggestion to make to the committee as to what should be done with respect to the social assets of these towns and the prospects for the future?

Mr. RIEVE. I think that one thing can be done. I believe that, first, we will have to adopt a more uniform taxation system in this country. When I say taxation I mean in all of its forms. I think that any State or any community that indebts itself in order to put up buildings and attract industry is robbing something from another community that has those mills.

Mr. PIKE. Do you feel the same way about wage differentials?

Mr. RIEVE. I certainly do, I certainly do.

Mr. PIKE. Do you still have the problem of a rather different form of town, that is the out-and-out company town which was built for the company and has been a source of a lot of trouble in your industry and some others? That is not as serious, I take it, as it was.

Mr. RIEVE. It is not as serious as it used to be. The company town is tending to disappear. If the Housing Authority—and they can do a very good job in these company towns—would get around there and build a few Government houses the company town would disappear over night.

Mr. PIKE. But you don't have that problem of there being only one store in the town?

Mr. RIEVE. Oh, yes; it is still there, it is still acute, and union organizers are still kidnaped and thrown out of towns. It is still there, but I am rather inclined to believe that it is not quite as acute as it was. It is declining in importance.

Mr. PIKE. That would be my general view.

Mr. RIEVE. But it is still there.

Acting Chairman WILLIAMS. Are you through with Mr. Rieve?

Dr. ANDERSON. Yes, sir.

Acting Chairman WILLIAMS. Thank you very much for your appearance. We have enjoyed your presentation. It is very useful to us.

What have you for this afternoon?

Dr. ANDERSON. We have the management side of the same problem, Mr. G. H. Conze, president of the Susquehanna Silk Mills.

Acting Chairman WILLIAMS. The committee will recess until 2:30. (Whereupon, at 12:45 p. m. the committee recessed until 2:30 p. m. of the same day.)

AFTERNOON SESSION

The hearing was resumed at 2:40 o'clock, upon the expiration of the recess, Mr. Joseph J. O'Connell presiding.

Dr. ANDERSON. Mr. Chairman, this morning we had a witness who discussed the textile industry from the standpoint of labor. This afternoon we are to hear Mr. G. H. Conze, president of the Susquehanna Silk Mills, of New York City, and Miss I. L. Blunt, secretary

of the National Federation of Textiles. They are ready to be sworn and to testify.

Acting Chairman O'CONNELL. Are both of these people to testify?

Dr. ANDERSON. Yes.

Acting Chairman O'CONNELL. Do each of you solemnly swear that the testimony that you are about to give in this proceeding will be the truth, the whole truth, and nothing but the truth, so help you God?

Mr. CONZE. I do.

Miss BLUNT. I do.

TESTIMONY OF G. R. CONZE, PRESIDENT, SUSQUEHANNA SILK MILLS, NEW YORK, N. Y., AND MISS I. L. BLUNT, SECRETARY, NATIONAL FEDERATION OF TEXTILES, NEW YORK, N. Y.

Dr. ANDERSON. Mr. Conze, you are president of the Susquehanna Silk Mills?

Mr. CONZE. I am.

Dr. ANDERSON. What is the nature of that mill?

Mr. CONZE. It used to be silk weaving; recently rayon weaving.

Dr. ANDERSON. How long have you been identified with the textile industry?

Mr. CONZE. I began 30 years ago.

Dr. ANDERSON. In this country?

Mr. CONZE. Yes.

Dr. ANDERSON. In that time have your operations extended to other than the silk field?

Mr. CONZE. No; only the silk field, and the rayon field later.

Dr. ANDERSON. And it is in the rayon and silk field that much of the change which we have been discussing has taken place?

Mr. CONZE. That is correct.

Dr. ANDERSON. And you are prepared to discuss what has occurred?

Mr. CONZE. Yes.

As in many other industries, technological development in the textile industry has meant the supplying of its products at lower cost to the public, and expansion of the industry's activity for management and worker alike. But in considering the effects of such changes on the stabilization of employment, and, equally important, the stabilization of business investment as the incentive for greater industrial development, we have seen both a bright and dark picture in the last decade. The principal tools used in effecting the change have been the introduction of so-called man-made fibers and the perfecting of the automatic machinery that could use those fibers in finer fabrics at lower cost of production. These changes have proven a boon to the consuming public in that they have brought within the reach of the modest pocketbook fabrics of luxurious appearance and excellent durability. They have also proved a boon to the workers in the new rayon yarn plants and have meant increased employment in the textile machinery establishments. But some of the long-range benefits are lost sight of in concern over the future of mill owners and workers whose income has been disrupted and whose future working life has been already killed or seriously threatened. Prominent in this group are the people whose life work was invested or being spent in the plants of the fabric-weaving industry formerly using silk for its raw material.

SHIFT FROM SILK TO RAYON

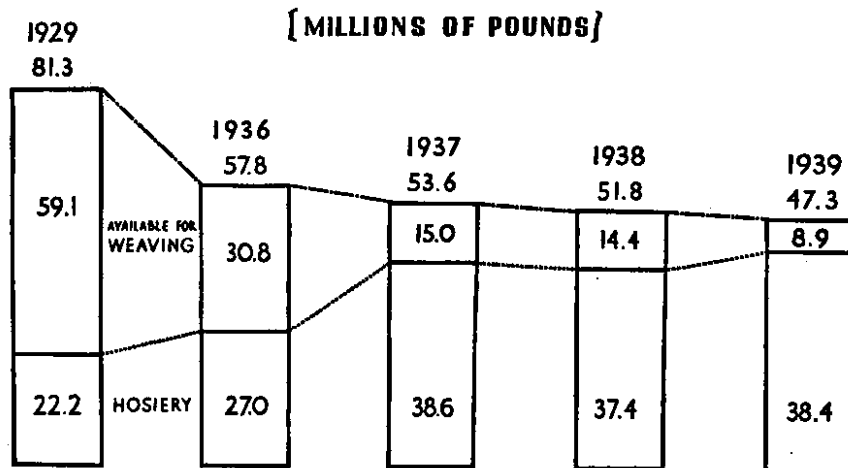

Mr. CONZE. Today, to all intents and purposes, the silk-weaving industry no longer exists. The fabric-weaving industry uses only a very small percentage of the silk imported into this country, as you will see from "Exhibit No. 2628," a chart showing the distribution of silk between the two principal consuming industries, weaving and the knitting of hosiery.

Acting Chairman O'CONNELL. The exhibit may be received. (The chart referred to was marked "Exhibit No. 2628" and appears below.)

EXHIBIT No. 2628

[Submitted by the National Federation of Textiles, Inc.]

**DISTRIBUTION OF SILK
BY TRADES**

SOURCE: RAYON ORGANON

You see on this chart that in 1929, 81,300,000 pounds of raw silk were imported into this country, of which 59,100,000 were used for weaving. At that time 22,200,000 pounds were used for hosiery and you see how the weaving share has progressively decreased and the hosiery share has increased, so that for the year 1939, while the total of silk used dropped to 47,300,000, weaving used only 8,900,000, hosiery 38,400,000. I might say that for 1940, I am positive the weaving will be less than last year.

It is the latter field, the hosiery field, which today can be more properly described as the silk industry, and even there a new man-made fiber, nylon, looms ominously over the figure of silk.

Because of my long association with silk-weaving mills, I have been asked to describe to you, as a matter of interest in considering

the effects of technological change, what has happened to this group of mills which in 1927, according to the census of manufacturers, had 1,648 establishments employing 127,643 wage earners, with an annual pay roll of \$140,054,000. It was located principally in Pennsylvania, New Jersey, and in the New England districts. Today, the industry has changed so in character that the 1937 census combines the figures for silk and rayon, and we are only part of a large group making rayon fabrics.

Dr. ANDERSON. May I interrupt to call the committee's attention to the fact that the charts are in large form on the easel.

Mr. CONZE. This group comprises now three types of mills: 1. Former cotton mills which reorganized for rayon weaving. 2. New mills organized solely for rayon weaving. 3. Former silk mills which adjusted their existing equipment to rayon weaving.

As some indication of what has happened in 10 years, we find that the 1937 figures show that the combined establishments of these three groups total only 848, about half the 1927 figure; that the wage earners are now 116,839, a reduction of 10.5 percent; and the total pay rolls are \$92,440,000, a reduction of 34 percent. And it should be remembered that this latter figure includes substantial increases in wage rates for the lower paid workers following the N. R. A. The amount of the reduction reflects the limited amount of work available for many workers. And it is the workers in the silk mills who represent a large part of this part-time or no-time activity.

From the economic point of view, our problem might be described as the difficulty of coordinating the most economical methods of production with the distribution methods most acceptable to all our consuming trades, starting with the retailer. In the textile industry, the maximum efficiency of a loom is a production schedule which will bring the fabric to its lowest unit cost. Such a schedule calls for the latest type of automatic looms operating on a continuous basis, that is, 24 hours a day every workday of the year. The manufacturer who wants to make the most of his machinery and give his workers steady employment must follow such a schedule. In contrast to this, consumers and wholesale purchasers of textiles follow a policy of close hand-to-mouth buying at most irregular intervals, dictated by season or style changes. This can mean only that any producer of style merchandise finds stability impossible. The necessity of making merchandise to fit in with these seasonal and style changes is likely to wreak havoc with any plan of the fabric manufacturer for stability in operation and employment.

The group of mills with which I am most familiar is engaged in a life-and-death struggle to reconcile these two divergent elements. It is a struggle shared by labor and management. To make the circumstances more understandable, consider the background of the so-called silk industry in the United States.

Up to the 1860's silk manufacturing was confined to crude experiments in the making of silk thread, silk handkerchiefs, and so forth, but cloth was still an import. But the development in Europe of the power loom for weaving silk cloth heralded the beginning of the real American-silk industry. The handicap of few skilled workmen was overcome. For the teaching of new workers, the industry was indebted to a large group of experienced English weavers who emi-

grated to America as a result of the closing down of the British silk industry. Following a reciprocal trade treaty between Great Britain and France, all duties on manufactured silk entering Great Britain were removed, and the result crippled the English mills. The emigrés settled largely in Paterson, N. J., and it was here that the first weaving mills were started on a large scale.

Rapidly the industry grew through the last part of the nineteenth century and the first two decades of the twentieth century. Improvements in some of the preparatory machinery, in the process termed "throwing" (an old Anglo-Saxon term meaning to twist), enabled the New Jersey weavers to move to new territories where unskilled operators could be used at a lower labor cost. The silk-throwing mills appeared in many villages and hamlets in the coal-mining regions of Pennsylvania to give employment to the women folk of the miners. Operation of this machinery provided light work that women could do efficiently.

That period was the prologue for a fabulous period of prosperity, and demand for silk fabrics, that followed the World War. Silk became the everyday dress of the average woman. The ready-to-wear manufacturing industry began to take hold, with its consumption of thousands of pieces of 60 yards each, instead of the few hundred yards that the average retail store could handle. "More and more machinery," was the cry. Every effort was made to speed up the loom action; new plants were built rapidly. Prices for the finished fabrics were whatever the manufacturer wanted to ask. A new development took place with the advent of crepe-twisting machinery, that is, the twisting of several single threads of silk into a tight twist to produce an effect of creping in the fabrics. This brought with it the development of a fabric that must be woven directly from the raw threads, without previous dyeing. We term such fabrics "piece dyed," meaning the fabrics are dyed in the piece rather than in the skein. It was the introduction of piece-dyed fabrics, or, rather, the weaving of fabrics in the "greige" or natural silk thread, that was at first the fortune and then the handicap of the industry. Previously, silk fabrics were woven from dyed yarn or "skein." Skein-dyed silks cannot be turned out hurriedly, and it is a complicated procedure. Piece-dyed fabrics, on the contrary, can be turned out quickly and steadily and kept in stock until ready for dyeing into popular colors of the moment. It was about this time that many mills began to realize that continuous operation of the machines would lower the unit cost of the product, as the overhead could be shared by that much more yardage. The result was year-by-year increase in production.

As profits were substantial, because of high demand for silk fabrics in this era, there was additional inducement to continue producing at a high peak. This hectic period was abetted by the introduction of new processes that permitted the weighting of silk fabrics so that the same amount of raw material would go farther in producing a yard of fabric. The weighting of silk involves the soaking of the silk thread in a solution that, through some characteristic of the silk thread, is absorbed into the fiber and can make the thread increase its normal size. As raw-material cost in a silk-manufacturing plant is a very important factor, the evolution of successful weighting of material was another big step in reducing costs and making silk fabrics avail-

able to more people of lower incomes. Huge plants were established, and there seemed no end to the demand for the merchandise.

But here and there, doubts were expressed. A group of manufacturers in their trade association, the Silk Association of America, Inc., discussed in 1922 the formation of a statistical reporting service on production and sales so as to get some idea of the stock on hand. As indicative of the times, one of the difficulties in establishing the service was to secure figures from some firms on the amount of their sales. It could be expressed only in dollars; records were not kept of yardages. The only yardage record was production and, once a year, inventory. Sales records were a minor consideration in the industry's plan of operation except to boast of increased dollar volume. Inventory control, or the idea of gauging production to demand, was unheard of.

But in the next 5 years increasing concern was felt about the burdensome stocks of fabrics on hand. Idle machinery became more common. Competition was being felt from small operators who had bought at very low prices looms discarded by the larger manufacturers as new models appeared.

By 1927 appeared a new factor, the rising development of a new fiber originally termed "artificial silk," subsequently given the generic name "rayon" and destined to do exactly what its inventor, Chardonnet, dreamed it would do—supplant the natural thread of the silk cocoon. And following rayon came another problem, the growth of the automatic loom.

INTRODUCTION OF AUTOMATIC LOOMS

Automatic looms were being used to a small extent in the silk industry. They made it possible to give 6 to 8 looms to a weaver instead of the customary 2 and 4 nonautomatic looms. But when the same looms were used on rayon, the loom assignment could be doubled. The reason is that rayon yarn is made with chemical and mechanical precision, which permits more rapid and smoother running than silk. The unit cost of a yard of goods was reduced to some extent, but the real reduction of costs has been made through the improvement in the automatic rayon looms built within the last 10 years. Loom improvement and greater speed, combined with greater perfection of rayon yarn in uniformity and strength, has meant an increase of the looms per worker from 24 to 36 and more. Nor has loom improvement reached its peak. In some cases looms manufactured in 1937 and considered extremely modern are being offered for sale at half price by used-machinery dealers today. Three or four years from now the looms rated today as the last word in weaving ingenuity will be as out of date as the nonautomatic looms of yesterday are now.

A recent case was reported to me of a rayon-weaving mill in New England, formerly a cotton mill, which today has 320 modern looms cared for by 8 weavers, 2 loom fixers, and 2 bobbin hands, a total of 12 men for each shift. Ten years ago 320 looms of that time would have required at least 40 weavers and 6 loom fixers, a total of 46 men for each shift. As significant of the change in the manpower required to produce a given amount of merchandise, consider the comparison

of yards produced to wage earners, based on data from the United States Census of Manufacturers.

You see there that, from 1927 on, the output per worker has more than doubled, and I am quite positive that this tendency is going on. As the old looms disappear, the output per worker will show a rising curve, as it has right along over the last few years.

PRODUCTION OF SILK & RAYON WOVEN GOODS PER WAGE EARNER [AVERAGE FOR YEAR]

SOURCE: CENSUS OF MANUFACTURES

CHART NO. 2

Mr. CONZE. This new textile fiber, the first in all the centuries since the discovery of cotton, wool, and silk, the product of man's research and ingenuity, has carried on the job begun when silk first became the luxury of the multitude, and has far outshone her older cousins. Rayon has been termed the "great common denominator" of the textile industry, for today it is found in the cotton, silk, and wool mills to a greater or lesser degree. It has provided men, women, and children with attractive clothing at the lowest prices ever seen, and has supplied luxurious draperies, bedspreads, and other household articles that would have been considered the sign of ostentatious wealth a few years ago, at a price within the reach of the most moderate.

The use of rayon on highly efficient machinery has advanced to undreamed-of heights during the past decade. The census figures show a clear picture of what has happened. "Exhibit No. 2630" shows

that in 1929 the combined production of rayon and silk woven goods was 742,775,000 yards. In 1939, this had grown to 1,330,000,000.

(The chart referred to was marked "Exhibit No. 2630" and appears below.)

EXHIBIT No. 2630

PRODUCTION OF WOVEN GOODS (THOUSANDS OF YARDS)

SOURCE: BUREAU OF MANUFACTURES

CHART NO. 3

Mr. CONZE. The significant fact is that the 1929 production of rayon or rayon-mixed fabrics was 251,115,000 yards and the 1939 production 1,250,000,000. Silk, on the contrary, showed in 1929 a production of 491,661,000 yards and in 1939 only 80,000,000. In the case of rayon, production increased in 10 years, 397.8 percent. In the case of silk, there was a decrease of 83.7 percent. The production record of the two fibers in cloth is shown in "Exhibit No. 2630." I am positive that in the current year rayon will increase and silk will drop materially.

The first rayon fabrics were woven in a silk plant in 1914. The silk mill was the normal place for the development and use of rayon. By the time the National Industrial Recovery Act was enacted, in 1933, many of the former silk manufacturers had turned to rayon for all or a major part of their production. From the viewpoint of convenience in use, rayon offers many advantages over silk. Silk is the natural fiber of the cocoon. It is subject to all the vagaries of any natural product. It must be carefully and painstakingly handled if the resulting fabric is to pass the critical eye of the consumer. All of the fiber is purchased abroad either directly or through agents in this country, and commitments were usually made for months in advance. Constant fluctuation in price of raw material is another of the hazards that makes silk manufacturing a precarious business compared with plants engaged in other fiber processing. Rayon on the other hand is most uniform in size, strength, evenness, and so forth. Because it is made by a limited number of producers it shows a fair

stability in price. In fact, rayon has shown a price structure typical of large industries in this country, like automobiles, where the greater the production the lower the cost. To the silk manufacturer, a steady supply of raw material at low cost and steady price presented an entirely new picture of production planning than had been the case in silk.

The next chart will show you the contrast between silk and rayon prices over the last 13 years. You find there that silk dropped from \$5.50 in 1927, touched \$1 in 1934, went back to over \$4 this winter, and has dropped to \$2.50 now.

SPOT SILK AND RAYON PRICES YEARLY AVERAGES

Source: Rayon Organon

Chart No. 4

Acting Chairman O'CONNELL. I understand you attribute the relative stability of price of rayon to the fact that there are few producers in the field, few large units?

Mr. CONZE. Few very large units.

Acting Chairman O'CONNELL. And in the silk industry you have a multitude of small establishments, or have had.

Mr. CONZE. Raw silk is a product of the farmer. It is reeled in Japan and is in the hands of a multitude of small farmers, and is subject to speculation or trading on exchanges in Japan.

Acting Chairman O'CONNELL. The instability is to a substantial extent in the raw silk.

Mr. CONZE. Yes.

Acting Chairman O'CONNELL. That is the raw-silk price?

Mr. CONZE. Yes.

Mr. PIKE. Do you have crop years there?

Mr. CONZE. Exactly. Silk, being the product of the farmer, is subject to nature.

Mr. PIKE. There are great ups and downs in the various years and difference in the amounts from year to year?

Mr. CONZE. Yes; different in amount from one year to another.

Acting Chairman O'CONNELL. Have you anything showing what sort of picture the woven product would show in price? Does the finished product fluctuate as much as this?

Mr. CONZE. I have something here on that.

Then you have the rayon yarn which for 7 or 8 years has been quite stable, it has fluctuated very little.

The next chart shows the consumption of these two fibers in millions of pounds in the United States.

Acting Chairman O'CONNELL. It may be received.

(The chart referred to was marked "Exhibit No. 2632" and appears below.)

EXHIBIT No. 2632

[Submitted by the National Federation of Textiles, Inc.]

UNITED STATES CONSUMPTION RAW SILK AND RAYON YARN

SOURCE: RAYON ORGANIZER

CHART NO. 5

Mr. CONZE. This shows the annual consumption in the weaving industry between silk and rayon in millions of pounds. You see the phenomenal growth of rayon used in weaving, from 48,500,000 pounds in 1929 to 285,700,000 last year, whereas silk dropped from 59,100,000 to 8,900,000. That is why I say the silk industry no longer exists, and if you take the year 1940, this 8.9 will look big in comparison.

SHIFT OF PRODUCTION AWAY FROM SILK MILLS

Mr. CONZE. While the silk industry was transferring its interests to rayon, another group had also started—the cotton manufacturer of fine goods. He had lost his cotton fabric market to the silk manufacturer following the boom days of silk after the World War. He now started the manufacture of rayon fabrics, with the advantage of generally lower wage costs, at the time, than the silk mills.

In addition to the cotton group new units were formed for rayon weaving exclusively. These new firms started operations with new plants, new machinery, and new methods of production and distribution.

By 1933, then, we have the three groups operating on rayon fabrics. By 1940, the bulk of the rayon yarn was being woven by reorganized cotton mills or new rayon mills. What about the silk mill?

In a few isolated cases, former silk manufacturers have installed the same high-speed machinery as the other groups. But mills not equipped with machinery in this class, or whose operations are concentrated in certain specialties in which they excel, have found it difficult to overcome the already existing general difficulties of bad coordination between production and demand, as mentioned previously. The silk manufacturer was accustomed to working on high-style merchandise. Expensive raw material was used. Distribution cost was high due to special services in designing, style obsolescence, the smaller volume sold. The fabric price structure, in dyed and finished materials, 15 years ago, averaged from \$1.25 to \$2 a yard. The selling price included a sufficient margin of profit to allow for expense. Rayon fabric prices, on the other hand, today do not carry the same opportunity for meeting overhead costs. Their prices, in the dyed and finished material, average from 35 to 65 cents a yard. The margin of profit must be figured in pennies. The silk manufacturer has found it very difficult to adjust himself to thinking in terms of mass production at low unit cost and a small profit per yard.

Because the ordinary silk loom could make the rayon fabric satisfactorily from the quality viewpoint, many silk manufacturers during the last 10 years have made a desperate attempt to compete with the better equipped and therefore lower cost mill for the rayon-fabric business. In the race with lower and lower costs in the newly equipped mill, the silk manufacturer fought a losing battle.

Incidentally, in addition to the problem of competing with low-cost producers, silk men frequently also had on their hands the problem of carrying their fixed investments, and in referring to those I would like to express my feeling of discouragement over the attitude of many localities in respect to old and new plants. While it has been for many years a widely practiced policy, I believe that offering

tax exemption and other inducements to bring new plants into a community is uneconomic from an industry viewpoint. The new manufacturer starts off with a big advantage over his longer established competitor, because he usually has newer equipment. If, in addition, he is given tax favors, it intensifies the competitive problem of the older mill, sometimes even in the same town. (In our industry plants are not widely separated over the country and in these days of automotive transportation, no village is too far from the nearest mill town. We are a relatively concentrated industry geographically.)

I can appreciate the ambitions of smaller communities who out of local pride desire to see their industrial life added to, but it is not helpful to industry in general. If they must do something to help industry, they might consider giving preferential treatment for already established plants. This community aid is responsible in large part for the migration of plants in our industry, although the silk industry has not suffered from that as much as cotton. In recent years the standardization of labor rates by law has been a great help in preventing competition through decreased labor costs, so that a change of policy on the part of community would help to stabilize conditions.

Today, the 108,308 silk looms recorded by the Census of Manufacturers for the silk industry in 1927 are virtually obsolete. In a report issued in 1937 by the Crompton & Knowles Loom Works, it was stated that, "only the looms that are less than 10 years old can be classed as modern from the economic standpoint." This same report shows that in 1936, 86 percent of the nonautomatic silk and rayon looms (owned almost entirely by the silk manufacturing industry) were obsolete. Today, it may be said that they all are; in fact, nonautomatic looms for rayon are no longer built.

In commenting on this situation, the report states:

Automatic loom is replacing rapidly the nonautomatic loom in the silk and rayon class * * * the cessation of nonautomatic loom buying which took place in 1931 when the automatic shuttle changing S-3 loom was introduced. Increased activity in rayon weaving was accompanied by curtailed operation in silk weaving, in which nonautomatic looms predominate.

In terms of financial records, the silk industry is not a pleasant picture. Consider the reports of the Bureau of Internal Revenue on profits in the silk and rayon industry for 10 years.

I turn to the next chart.

(The chart referred to was marked "Exhibit No. 2633" and appears on p. 16889.)

Mr. CONZE. It goes only to 1936, but I don't think there would be a material change for the last 3 years. You see a constant decline.

This report gives only the number of establishments. It does not give dollars and cents.

Dr. ANDERSON. What would the dollar figures look like?

Mr. CONZE. It certainly would not change the picture materially.

Dr. ANDERSON. Is it true that many corporations which were on the verge of bankruptcy at the bottom of the depression have since gone bankrupt, and this is, therefore, a clearer picture than we had in '33?

Mr. CONZE. Yes; I would say so.

Dr. ANDERSON. So that even with the selective basis that we now have, a very substantial percentage do not show profits.

Mr. CONZE. That is quite right.

Dr. ANDERSON. Is the liquidation process still going on?

Mr. CONZE. Yes, it is.

As an example of the mortality rate in the industry, also consider a record given to me by our trade association, the National Federation of Textiles, Inc. (the significant current name of our old association, the Silk Association of America, Inc.). In an analysis made

EXHIBIT No. 2633

**INCOME REPORTS
OF
SILK AND RAYON WEAVING MILLS**

CORPORATIONS REPORTING NET INCOME

CORPORATIONS REPORTING NO NET INCOME

SOURCE: BUREAU OF INTERNAL REVENUE

in December 1938, it was found that of 131 weaving firms enrolled as members of the association in 1924, only 14 years earlier, 84 had disappeared completely and of the 47 remaining, 17 were in the hands of receivers or had reorganized after bankruptcy proceedings. The year 1939 did not make the picture any brighter.

At the present time, those who have weathered the storm so far are those who have been able to install the new machinery necessary for efficient production of staple fabrics, in competition with the old cotton mills or new rayon firms, or to specialize on particular fabrics that are less commonly made. It is an industry considerably shrunken in size, both in machinery owned and in the number em-

ployed. Plants have been sold or written off for a nominal value. The number of establishments has decreased from 1,648 in 1927 to 848 in 1937. Value of products has dropped from \$750,000,000 in 1927 to \$405,000,000 in 1937, and the 1937 figure includes all rayon, not only that in silk mills. Former silk workers have found their way into other fields, and it may be that the future of the industry will follow along the lines described by Dr. Bell of Brookings Institution. During his testimony earlier in these hearings, Dr. Kreps quoted Dr. Bell as saying that when "output of workers exceeds the expansion of productive capacity, new employment is created, and a prosperous condition results which brings mutual benefits to all three major divisions of industry—wage earners, salaried workers, and investors."

REDUCTION IN SILK AND RAYON PRICES

Mr. CONZE. Certainly the industry is following his recommendation that consumers be given the benefit of any saving in lower cost of production, through the supplying of better merchandise at lower price. The consuming public today is getting excellent value for very little money in the purchase of fine dress fabrics. And the production per worker is vastly increased as was shown in "Exhibit No. 2629," giving the ratio between the number of wage earners and the yardage produced from 1927 to 1939.

Acting Chairman O'CONNELL. May I interrupt? Some general picture of what has happened to prices can be obtained by comparing the total production of woven goods, which I think has more than doubled between 1927 and 1939, although you have just indicated the value of the product in comparable years is not much more than half.

Mr. CONZE. That is why I gave you a price range. Ten years ago the average price, wholesale, ranged from \$1.25 to \$2, and today it runs from 35 to 60 cents. It is very difficult to give you an exact comparison, because we are dealing with styles, and what was fashionable 10 years ago is no longer fashionable today. I can give you a price range, and it is, at wholesale, about one-third of what it was 10 years ago.

Using a fiber-like rayon, that is stable in price, easy to secure, uniform in quality, on looms that can be operated for less cost at higher efficiency, points favorably to the possibilities of better planning and steadier operations in the future for those who can survive. With these two factors must also be considered the reduced risk in manufacturing operations caused by the fact that the raw material is much lower in price and that the improvement of rayon yarn production is eliminating more and more of the auxiliary machinery we needed for silk; moreover, the heavier nature of the rayon yarn means that it takes less threads per inch of fabric to achieve a yard of merchandise. For example, new high-speed warpers, the machines that prepare the lengthwise thread for the loom, have eliminated many of the workers in that department, formerly one of the most highly skilled operations. Today warps can be woven in much longer length, reducing the handling in the loom and loom delays. The longer warp ties up more yarn in the preparatory stages of weaving,

but with the reduced cost of our raw material that is not a serious objection. It has been estimated that the new automatic auxiliary machinery has reduced the help in these departments by about two-thirds. Today 3,000-yard warps are not uncommon where 300 yards was about the limit 10 years ago.

One big problem still remains, the buying habits of our consuming groups. The average worker wants steady employment, but as far as textiles are concerned, his buying habits are quite to the contrary. And because of his buying habits, his immediate suppliers, the retailers, follow an irregular, at times erratic, policy of demand for specific fabrics and garments. The garment maker in turn makes equally erratic demands for delivery of needed material. He follows closely the demands of the retailer for seasonable and style merchandise. As long as he does, he is unable to sustain any stability in operation, since he cannot accumulate stock. As a result, his demands upon the fabric manufacturer are for immediate delivery, frequently for fabrics or colors not being made at the moment. Not uncommonly, by the time the fabric he demands is woven and ready for delivery he is no longer as eager for it, or rather his customers are not. The result is too often a sacrificing sale on the part of the mill man of merchandise which is still as desirable in quality as it was before, but which a style change makes a drug on the market. The garment manufacturer, in his predicament, is helped somewhat by the employment situation in his industry. It is the custom to take on and lay off workers as they are needed, often without any previous notice, at the end of the day's work. Fortunately or unfortunately, the industry is so concentrated in New York City that workers are available immediately. On the other hand, the fabric manufacturer finds it very difficult, if not impossible, to operate on such a basis. He must keep his workers in the mill if he is to maintain any kind of standard of workmanship, and does the best he can to guess what the dress trade will want. The result, however, is not helpful in maintaining a balance between production and demand and a stable price level.

Remedies for the situation are not easily defined. There has, for a long period, been a strong feeling among a large group of manufacturers that the elimination of the so-called night shift, or the third shift, would not only be a mark of economic improvement but constructive social progress as well, from the viewpoint of the workers in the mills. From the economic viewpoint, the supporters of this plan believe that what the industry needs is more stability and regularity of production. With the amount of equipment available for use, such regularity has a better chance both from the interests of betterplanning by the management and steadier employment for the worker, if production is based on two shifts. From the social or health point of view, both management and labor groups believe that the worker on the third shift suffers both mentally and physically, and without any real necessity, if real demand for that production is considered. Furthermore, limitation of operations to two shifts will mean more rapid installation of new machinery. More machinery will be needed in the 2 shifts to attain the same production as 3 shifts of a smaller number of looms. The supporters of continuous operation contend, on the other hand, that if free enterprise and free competition for the public market are to be

maintained, then whatever system of manufacturing brings the lowest cost to the public is the most desirable. It has been demonstrated that continuous operation of the newest types of automatic machinery is the most economical method of producing fabrics, and the prices at which the public buys today are proof that the resulting saving is being passed on to the consumer. Furthermore, in direct connection with our own industry, the advocates of third-shift operation point out that in a style industry, the answer to maintaining balance between production and demand is rapid production keeping up, not trying to catch up, with style cycle requirements. By keeping up, a mill can meet the demand while it exists and promptly start in with new demand when the style changes. The plant with slower rate of production frequently finds that by the time they are ready to deliver goods for which a style demand is apparent at the beginning of the production schedule, the merchandise is no longer wanted, and it is obsolete stock.

There are advocates of both policies, with no indication that their divergent views can be reconciled. At the present time, much seems to depend on whether the machinery owned by the proponent of either side is of the new or old type.

PROSPECTS OF CONTINUED MECHANIZATION

Mr. CONZE. On the basis of the 10 years past, however, both management and labor must look forward to continued mechanization of the industry. The tendency is definitely toward reduction in the number of wage earners necessary to turn out a given quantity of production. This will go on more and more as the old machinery is replaced. It will become more rapidly true if business conditions improve and there is new money available for the purchase of that machinery. Management will have the problem of finding a market to absorb the production of more and more efficient machines. Labor must look forward to finding new employment either in new processes in textiles or elsewhere. The use of man-made fibers, with their constantly decreased cost, to the exclusion of the natural fibers of silk, cotton, and wool will mean more merchandise at lower prices to the public at large, but less work for those accustomed to gain their livelihood in our mill. Indeed, one of the prominent silk manufacturers, when asked what he saw in the future for our industry, said that at the rate changes had taken place in the last 10 years, he did not consider improbable a future production of fabrics from man-made fibers that would begin with the raw material of the fiber and continue through highly efficient machinery through to the loom weaving the finished fabric, all with a modicum of human labor. The period of transition is even more difficult in some respects for the man who has built up a business than for the worker, whose investment is his labor only. Progress cannot be stopped, but whether the hardships of change can be lightened, I do not know.

Technology or no technology, what the average American wants is an opportunity to secure a fair income. If he is a textile manufacturer he wants to operate a plant that will produce fabrics with a fair profit and provide steady employment for the workers for whom he is responsible. If he is a textile worker I think he wants to feel that he can find employment in a well-equipped mill that will

give him an opportunity to show what he can do, and to earn a wage that is not only fair but relatively dependable. That has been possible during the past 10 years only to a limited extent, and the period in the meantime between old and new developments is not easy for either employer or employee. The reasons for the difficulty are complex, it is true, but what some of the difficulties are I have tried to outline to you in this history of the technological problems of the silk industry.

Since the textile industry in general was discussed here this morning, I want to say I am only competent to talk about the silk and rayon industry and not about cotton, wool, or rayon yarns, or the carpet industry.

Dr. ANDERSON. I notice you have some samples of materials there, and I wonder if you would explain to us what, precisely, is the difference between rayon and silk, and why rayon has moved into the field so rapidly.

Mr. CONZE. I brought these samples along to show you that it is very difficult for the layman to see the difference between silk and rayon.

Here, for instance, is a silk cloth that sold for around \$2 10 years ago. They are almost relics, some of them. One is a weighted silk and the other is pure silk.

Dr. ANDERSON. Weighted with what?

Mr. CONZE. A chemical composition of tin tetrachloride.

Mr. PIKE. Would these pieces be very much the same except for the weighting?

Mr. CONZE. The weighting makes it very much heavier and also makes it relatively cheaper.

Mr. PIKE. And it wears out a little faster?

Mr. CONZE. No; it wears perfectly all right.

Here you have an all-silk material which played a very important role years ago as a printed fabric, which also sold on its heyday around \$1.75.

Dr. ANDERSON. And how long ago was that?

Mr. CONZE. Twelve years ago.

Dr. ANDERSON. You paid \$1.75 a yard for that silk?

Mr. CONZE. Easily, wholesale. The public pays 50 percent more. The retailer would have a 50 percent mark-up over these prices, which are wholesale prices.

You have the relics of the past there. Now we are talking of what is going on today. This blue one is around 65 cents. You have two prints, one silk and one rayon, and I am quite sure that the rayon one today is just as satisfactory to the public as the other one, which was silk.

That is why rayon fabrics have taken such a hold; the public could not see any difference in them.

Mr. PIKE. What is the practical difference to the wearer, Mr. Conze?

Mr. CONZE. No difference.

Mr. PIKE. That's the trouble.

Mr. CONZE. In fact, I don't want to take sides between silk and rayon, but I am inclined to believe that rayon wears better than silk.

Dr. ANDERSON. What is rayon, really?

Mr. CONZE. Degenerated cellulose.

Mr. PIKE. Is this an acetate or viscose rayon?

Mr. CONZE. That is viscose. I have an acetate here, too.

Here again, for comparison, are a piece of acetate rayon and one of pure silk, used for the same purpose. They are both used for lining purposes, and the price of the silk is at least double that of the acetate.

Dr. ANDERSON. How long was it after rayon was invented before it became commercially practicable?

Mr. CONZE. I don't know when Mr. Chardonnet made his invention, but when I started in business it was quite on its way. I think it was before 1900, in the late eighties if I am not mistaken.

Dr. ANDERSON. It was invented in the late eighties, and became commercially used, I suppose, early in the century.

Mr. CONZE. Yes; 1909 or '10.

Dr. ANDERSON. And about how long was it before it began to compete successfully with silk?

Mr. CONZE. I would say from 1930 on it became a serious competitor.

Mr. PIKE. They had to get their yarn sizes down.

Mr. CONZE. That is a development of the last few years, to get fine sizes. I think I have a chart here from 1929 on; 1929 was still a big silk-consuming year.

Acting Chairman O'CONNELL. Relatively, rayon was about half the production of silk in 1929.

Mr. CONZE. The last 10 years have really seen the greatest change.

Dr. ANDERSON. It took, then, about 15 or 20 years to move it into a position where it supplanted silk? Why was the time so long? Was there something wrong in the fabric itself, or did you have to overcome consumer prejudice? What was it?

Mr. CONZE. No; I think the perfection which rayon has attained during the last 10 years is due to improvement in the yarn itself. A rayon thread of then and today don't compare at all, particularly from a millman's viewpoint. A rayon thread of 10 years ago wouldn't run, and one of today is perfect.

Mr. PIKE. For the wearer, too, the early rayon fabrics, when they got wet, gained a lot of weight and wouldn't hold their shape.

FUTURE OF FIBER INDUSTRY

Mr. CONZE. That is all a matter of the past. Rayon is an article which gives perfect wearing satisfaction.

Dr. ANDERSON. You hinted at the possibility of new fibers and resulting new fabrics. Did you have anything in mind when you did that?

Mr. CONZE. At the present time there has been much publicity given to nylon. Nylon is going to be used first of all in hosiery, but that doesn't mean at all that either nylon or similar projects will not revolutionize the rayon products.

Mr. PIKE. Has it been put on the loom at all?

Mr. CONZE. It is relatively expensive and does not give any advantage over the viscose or acetate yarns.

Another thing, I think the viscose and acetate yarns will make further progress. In fact, I think the Celanese Corporation, in its

annual report only a few weeks ago, spoke of having a yarn which was twice the strength of their normal yarn. What that is going to mean in the fabric market in the future is very hard for anybody to see.

Mr. PIKE. We haven't brought out any of these casein products in this country, the Italian wool substitutes?

Mr. CONZE. They would go more into spun rayon. I have not touched on the spun rayon. I think those products would go into spun rayon, wool spun, and mixtures of wool and cotton.

Dr. ANDERSON. Do you think it would take a new fiber as long to move in and capture the market, as it did rayon?

Mr. CONZE. No; I think it would go faster this time.

Dr. ANDERSON. And what do you think would be the effect upon the technology of the industry and its labor force?

Mr. CONZE. I don't want to prophesy. If you had asked me 10 years ago what rayon would do to the silk industry or to those that were making rayon, I don't think anybody could have foretold what happened. So I don't want to prophesy what is going to come because I know that 10 years ago no one could have foreseen the tremendous change that all of us have witnessed.

Dr. ANDERSON. That leads to a question of great importance. You as a silk manufacturer 10 years ago did not foresee this possibility?

Mr. CONZE. No.

Dr. ANDERSON. Ten years ago you had a heavy investment in silk mills?

Mr. CONZE. That is right.

Dr. ANDERSON. What occurred? How did you meet this changing technology in fiber?

Mr. CONZE. As I said in my brief, the machinery which manufactured silk could also manufacture rayon, so we could just put rayon on our looms and manufacture as we did before. But the new rayon machinery that was developed beat the old silk equipment, so that today it is totally obsolete.

Dr. ANDERSON. In other words, you had to meet a new machinery that had been developed.

Mr. CONZE. We had to do two things—meet a new machine and a new material. The new material we could have coped with; in fact, we did, but the new machine was so superior to what we had, because it has been adapted to the new fiber, that the silk loom and all its equipment is obsolete.

Dr. ANDERSON. What happens when a manufacturer like yourself must meet such a problem?

Mr. CONZE. You must either completely mechanize your mill or concentrate on specialties, as my concern has done.

Dr. ANDERSON. There are two outs, then, for you—go into specialties or meet the competition in the same field.

Mr. CONZE. Or a third: fold up.

Dr. ANDERSON. And that third has been pretty generally practiced, has it not?

Mr. CONZE. To a great extent; a very great extent.

Dr. ANDERSON. When you amortize your machinery, you mentioned in here that you would have to cover the cost within a very brief period of time. Do you anticipate such drastic changes as have occurred, and do you amortize over a brief period of time?

Mr. CONZE. I don't think anybody expected any such developments 5 or 6 years ago. The latest machinery, which is so far superior to what existed before, has, overnight, made obsolete a lot of machinery which was fairly good 4 or 5 years ago.

Dr. ANDERSON. So there is no way to amortize that?

Mr. CONZE. No.

Dr. ANDERSON. Is that the condition of the industry now, or are you amortizing your new machinery over a brief period of time?

Mr. CONZE. I would say that it is individual. Individual concerns have to use their own judgment.

Dr. ANDERSON. But the factor of machinery is the outstanding factor in this change?

Mr. CONZE. It is new machinery for a new product. If you had built this same machinery for the rayon of 10 years ago it would not have worked.

Mr. PIKE. It wouldn't work on silk, either then or now?

Mr. CONZE. No; it is only adaptable to rayon, but the rayon of 10 years ago wouldn't work on the present machinery. Rayon has increased so much in evenness and elasticity and strength that these developments have become possible.

Dr. ANDERSON. In your own plant, what was the effect upon labor of the change-over as you changed from silk to rayon?

Mr. CONZE. In our concern we had a great number of plants, and we closed a great number. The ones in which we were running a staple fabric we sold.

Dr. ANDERSON. And dismissed the workers?

Mr. CONZE. We had plants distributed all over Pennsylvania and closed a good many of them, keeping only the specialized plants.

Dr. ANDERSON. Did it generally happen that where the change-over occurred workers were dismissed?

Mr. CONZE. Either they put in new machinery or closed up.

Mr. PIKE. Were most of these mills in towns where there was some other primary employment of labor, such as in coal towns? They were in a great measure auxiliary to some other industry?

Mr. CONZE. That is correct. As was mentioned this morning, I think, there are very few so-called ghost towns in the silk and rayon industry.

Mr. PIKE. At least not due to that.

Mr. CONZE. Not due to that; no.

LABOR DISPLACEMENT IN SILK MILLS

Acting Chairman O'CONNELL. From your figures I notice that from 1927 to 1937 there is a reduction in the wage earners in these three groups of mills of about 10.5 percent, so that is only a rough indication of the amount of displacement of labor.

Mr. CONZE. As I said, this reduction of 10 percent includes the two new groups of mills, the cotton mills that went into rayon and the new mills. If you refer to silk alone, for which there are no statistics available, I think you will find the old silk industry has dismissed 70 or 80 percent of its labor.

Acting Chairman O'CONNELL. What has happened to those men? Would they be skilled in working in rayon?

Mr. CONZE. Oh, yes; but these new rayon groups have grown up by themselves, either cotton mills going into rayon or new rayon establishments in the South.

Acting Chairman O'CONNELL. But a man skilled in the old work—

Mr. CONZE (interposing). Could go into rayon.

Acting Chairman O'CONNELL. There would be no retraining necessary?

Mr. CONZE. No.

Mr. PIKE. He would have to move to a new locality, however.

Mr. CONZE. He would have to move to a new locality, which many people have done.

Mr. MAGINNIS. Mr. Conze, what has been done in the silk mills around Paterson?

Mr. CONZE. I think they are closed up.

Mr. MAGINNIS. They are just closed, are they?

Mr. CONZE. At the present time Paterson, I understand, has quite a boom on account of the aviation industry.

Mr. MAGINNIS. They didn't change over to rayon at all?

Mr. CONZE. Very little, because rayon requires a lot of capital, and most Paterson mills were small concerns who could not buy new equipment.

Mr. MAGINNIS. I was interested because several years ago when I was practicing law in New York I had some business dealings with the mills over there, and I know there were some large silk mills all through Paterson.

Mr. CONZE. The largest ones had disappeared by 1930. In the last 10 years the small ones, whatever were left, disappeared.

Mr. MAGINNIS. United was still operating at that time.

Mr. CONZE. That is a dyeing concern. I was speaking of weaving. Since United was a leader in weighting they dropped out when weighting dropped out. They are operating on a reduced scale now.

Dr. ANDERSON. The introduction of this new fiber placed the silk manufacturer directly in competition not only with itself, but with other elements in the textile industry with which he didn't compete before?

Mr. CONZE. That is correct.

Dr. ANDERSON. In other words, it intensified competition?

Mr. CONZE. Very much so.

Dr. ANDERSON. What do you feel is the final solution? Is it desirable to unify the industry into a few larger units, or is it best to keep it as it is now, broken up into small competing unit?

Mr. CONZE. I don't think it has a tendency to consolidate itself into a few big units.

Dr. ANDERSON. There is no such tendency?

Mr. CONZE. While there are a few big units, they have not been accomplished by consolidation.

Dr. ANDERSON. Mergers do not seem to be the way to solve this problem?

Mr. CONZE. The textile industry is an industry of individual initiative and individual management.

Dr. ANDERSON. When you have to meet this new competition with installation of new machinery, what happens to the capitalization of your plant? Do you go into the market for money?

Mr. CONZE. If you can get it. You have to procure it. Either you have it or you have to find it.

Dr. ANDERSON. Is the industry in such a condition that you can go into the market?

Mr. CONZE. The survivors of the old silk industry, hardly. The new ones in the market got money for an entirely new enterprise. People preferred to go into an entirely new venture instead of financing a new project in an old one.

Mr. PIKE. This new material, I think I saw a picture of that in Life a few weeks ago.

Dr. ANDERSON. You spoke of limiting production. There seem to be at least two schools of thought, one in which textile operators hoped to make their way successfully by limiting the amount of product and the other in which they hoped to make their way successfully by expanding and increasing production as much as the traffic would bear.

Mr. CONZE. There is no question of that.

Dr. ANDERSON. Which school do you hold to?

Mr. CONZE. Since I don't have the new machinery, I am of the school that likes the 2 shifts. The fellow who owns older machinery likes 2 shifts and the fellow who has the latest machinery like the 3 shifts. It is quite obvious.

Dr. ANDERSON. In other words, it is self-protection?

Mr. CONZE. I think so.

Dr. ANDERSON. Would you care to comment on the effectiveness, in connection with technological unemployment, of dismissal wages and technological clauses in labor contracts with labor?

Mr. CONZE. Such procedure may be feasible in part of the industry. I particularly have in mind the rayon yarn producer, because I understand that is where these contracts have been made. First, the concerns that write such contracts must have the money to pay the dismissal wages. Second, if relatively few competitors are involved and they all do the same thing, it doesn't matter. In the case of the rayon yarn producer, as I said before, there are a relatively few big concerns involved so that it might be feasible there. It is certainly utterly unfeasible when it comes to the textile industry at large, because you deal with thousands of concerns.

Acting Chairman O'CONNELL. As a competitive proposition?

Mr. CONZE. The competitive proposition would make it impossible.

Acting Chairman O'CONNELL. If you don't do it, it puts those who do it at an entirely competitive disadvantage?

Mr. CONZE. It increases their cost.

Mr. PIKE. That would also hit pretty hard the company which went into quick style changes where you must stop on very short notice.

Mr. CONZE. That is right.

Dr. ANDERSON. What, if any, effect has this change-over from silk to rayon had upon international trade with the country concerned?

Mr. CONZE. Well, it happened to coincide with a very substantial increase in silk consumption by the hosiery industry. If that had not been the case, undoubtedly the Japanese trade would have suffered materially, but as "Exhibit No. 2619" shows, if you compare 1929, an exceptionally good year, with 1936, it is only a drop from 57,000,000 pounds to 47,000,000 pounds. That is not such a tre-

mendous figure, but if the silk had been limited to weaving only, that would have been a very substantial figure.

Mr. PIKE. Isn't it true that during this same period Japan has expanded its rayon manufacture so it is supposed to be the largest in the world?

Mr. CONZE. If I am not mistaken Japan is the biggest producer of rayon.

Mr. PIKE. I think so.

Dr. ANDERSON. Is that material competing with your product in this country?

Mr. CONZE. Once in a while, very little.

Acting Chairman O'CONNELL. Rayon products from Japan?

Mr. CONZE. Rayon yarn and rayon products.

Acting Chairman O'CONNELL. It does not represent effective competition?

Mr. CONZE. The importation of rayon yarns is very small.

Dr. ANDERSON. I have no further questions.

Acting Chairman O'CONNELL. Thank you very much, Mr. Conze. (The witness, Mr. Conze, was excused.)

Dr. ANDERSON. Mr. Byrl Whitney is here from the Brotherhood of Railroad Trainmen, and he is speaking as the representative of Mr. A. F. Whitney, president of the Brotherhood of Railroad Trainmen, Cleveland, Ohio. Mr. Whitney has a prepared statement, which is an important document, and should be included in the section on American railways.

Acting Chairman O'CONNELL. Do you solemnly swear that the testimony you are about to give in this proceeding will be the truth, the whole truth, and nothing but the truth, so help you God?

TESTIMONY OF BYRL WHITNEY, BROTHERHOOD OF RAILROAD TRAINMEN, CLEVELAND, OHIO

Dr. ANDERSON. What is your position?

Mr. WHITNEY. Byrl A. Whitney is my name, director of education and research of the Brotherhood of Railroad Trainmen, Cleveland, Ohio.

Dr. ANDERSON. You are speaking now for Mr. A. F. Whitney, president of the Brotherhood?

Mr. WHITNEY. That is right.

If it is agreeable with the committee, in view of the lateness of the hour, instead of reading this statement, which contains a lot of statistics, some of which you may be familiar with, I will just extend it into the record and highlight it in a few words.

Acting Chairman O'CONNELL. It will go in the record.

Mr. WHITNEY. The Brotherhood of Railroad Trainmen, an organization representing approximately 145,000 members employed in railroad-train and yard service and on bus lines in the United States, Canada, and Newfoundland, is keenly interested in the investigations and hearings sponsored by the Temporary National Economic Committee. We have long hoped that out of the great store of information amassed by various Government agencies, concerning the American economy, there would come some practical conclusions pointing the road toward the elimination of the Nation's No. 1 problem: unemployment.

Until the current inquiry, little had been done to show us a way out of our dilemma. There appears to be no end to the capacity of Congress to appoint investigating committees, but research cannot go on forever. It is not an end in itself. Moreover, there is a limit to the patience of the American people, particularly the jobless industrial workers, the migratory farm workers, the youth, and other exploited sections of our population, who desire, before all else, an immediate, practical, and effective solution to the problem of unemployment.

It is a sad commentary on our civilization that the forgotten man of the hour is the job hunter. Such injustice should stir the heart of every man of decency and of good will. Common sense should dictate the need of restoring opportunity to our citizenry and of giving everyone his rightful niche in society.

I am happy to say that the published reports of the hearings before this committee reveal that at last a serious and intelligent effort is being made to understand our economic problems with a view to correcting the evils and abuses that are manifest. I am particularly pleased that the T. N. E. C. has seen fit to project its studies into the railroad industry field, one of the most important branches of our national economy, and I appreciate the opportunity that has been afforded me to enter into the discussion on technology and unemployment in the railroad industry.

As you know, the railroad industry is the most statisticized industry in the country. I am sure that your committee has had access to the reports of the Interstate Commerce Commission and of the Bureau of Labor Statistics of the United States Department of Labor; therefore, I do not think it necessary to consume time by presenting all the statistics necessary to an understanding of the railroad industry. It will suffice if, in touching upon various phases of the topic under discussion, I cite merely pertinent data to illustrate my points.

EMPLOYMENT AND PAY ROLLS

Mr. WHITNEY. For the railroad worker, the depression began long before the 1929 debacle. Like the farmer, railroad labor suffered immediately following the World War. And now, after two decades, the railroad industry has been closed to more than a million men, and the pay roll has been cut by almost \$2,000,000,000. Truly a one-two knock-out punch!

The average number of workers employed by class I carriers in 1920 (excluding switching and terminal companies) was 2,022,832. Between 1920 and 1929, employment declined by 17.9 percent. In 1933, at the depth of the depression, the number was down to 971,196, or 48 percent of the 1920 figure. By 1937 employment on class I railroads had recovered to 1,114,663, but in 1938 it dropped to 939,171, the lowest point reached since the turn of the century. Estimates for 1939 show that employment rose last year to 987,943.

The extent to which railroad labor has suffered for lack of jobs is further revealed through a comparison of the index of employment in manufacturing industries with a similar index for railroad employment. This is illustrated by this table which I offer for the record.

(The table referred to was marked "Exhibit No. 2634" and is included in the appendix on p. 17433.)

Mr. WHITNEY. Between 1933 and 1937 employment in manufacturing industries had recovered 44.1 percent, whereas rail employment increased but 14.7 percent. By 1937 factory employment was 5.8 percent above the 1923-25 average, but rail employment was 37.6 percent below the 1923-25 average. Factory employment has shown a tendency to approximate the 1923-25 levels, but railroad employment lags far behind. Of course, we must not overlook the fact that our economy as a whole has failed to provide employment for the millions of new workers who have since entered the labor market. Current estimates of total unemployment cluster about the 10,000,000 mark.

There are certain unchallengeable facts with regard to the incidence of railroad unemployment. Railroad workers ordinarily have difficulty in finding employment in other industries, because the skills which they develop in their chosen occupations are not transferable. In times of depression, these difficulties are multiplied.

The unemployment of railroad workers has been the subject of investigation by the United States Department of Labor and, more recently, by the National Research Project of the W. P. A. The latter study found that, because of the almost universal application of the principle of seniority, for which labor has fought for so many years and succeeded in incorporating in contracts with the carriers, the unemployment which set in after 1923, and which was intensified after 1929, affected the younger workers much more, and more immediately, than the older workers. The investigation further revealed that unemployment resulting from permanent separations was supplemented to quite a large degree by short-period unemployment.

As the depression deepened in the years 1930 to 1932, furloughs increased in number and began to bear heavily on the longer-service employees. The rate of furlough among employees with 15 to 20 years of service reached an annual average of 9.8 percent for the 3-year period 1930-32, while even among employees with 30 or more years of service an annual average of 3.0 percent were furloughed during this period.¹

The National Research Project also reported that the longer the attachment to the industry, the more difficult it appeared to be to find work outside the industry.

The Department of Labor study which has been referred to (Carter Goodrich, *Earnings and Standards of Living of 1,000 Railway Employees During the Depression* (U. S. Department of Labor, May 22, 1934) has been summarized by the Brotherhood of Railroad Trainmen in a book entitled *Main Street—Not Wall Street*, published in 1938. I shall take the liberty of quoting from this summary, because it will serve to remind us of the human tragedies which befall the jobless.

This study encompassed 1,000 families of railway men in 18 localities from all parts of the country. Sixty-four percent of the men interviewed were at least 40 years of age. All these men were working in April 1933. "Any group of workers who still held jobs in 1933 was a selected one, and on the railroads the policy of seniority preference determined that the selection should be of men relatively old in years and service * * *. These were men who were in many ways better prepared than other employees to meet the emergency of the depression * * * a number of agents wrote back from the field that the basis of selection understated the degree of hardship among railroad employees."

¹ W. P. A. National Research Project, Summary of Findings to Date, March 1938, p. 136.

Despite the fact that the group selected was one with high seniority rating, nevertheless even this number was visibly affected by the ravages of the economic depression. The earnings and income of the 980 railroad men proper, in 1932, were such that 38% made less than \$1,000 in that year, two-thirds less than \$1,500. One hundred and two earned as little as \$500 in 1932, whereas 18% earned as much as \$1,750. Only 60 of the 980 men succeeded in supplementing their income by outside work. Other sources of income helped but little: "For the families included in the study the total income for the year 1932 was not much greater than the income of the chief breadwinner. In more than half the families, 58%, the income as calculated was less than \$1,500; in practically three-fourths it was less than \$1,750."

In the course of the depression, community services bogged down, failing to keep pace with increased community needs. Consequently the burdens of these families increased. Their incomes reduced, 38% of the families also had to contribute cash and groceries to relatives and friends in 1932. Families doubled-up in order to save on rent. At the same time, home lives were shattered as families, unable to maintain a single roof, scattered throughout the country in search of shelter.

Capital losses became the order of the day. Forty-four of these families lost their homes through foreclosure or forfeiture between 1929 and 1933; 38 of them lost all their investment. Half of the 884 families reporting had cash reserves at the beginning of the depression, but at the time of the study only 31 families had their savings intact. Forty-seven per cent of the families, or 464, dropped their life insurance policies to raise needed cash. For most of them, it meant that they could never take out new insurance, because rates would be prohibitive for men of their age. Accident insurance was also dropped, and to railway workers this was no small loss.

Not only did these families lose their homes, their savings, and their insurance, but they also incurred debts which, at the time of the study, were making life miserable for them. Seventy-four per cent of the families stated that they had outstanding debts or obligations incurred only since the beginning of the depression. "These debts were not only a strain on the meager resources of the chief breadwinner but also a source of worry and fear, since in normal times garnishment proceedings usually mean discharge for a railroad worker." One-fourth of the property owners were in arrears in tax payments; 39% were in arrears in payments of principal and interest on mortgages. One hundred and sixty-six families had borrowed money from friends or relatives, 135, in desperation, had gone to loan companies, where some of them were fleeced. Fifty-nine per cent of the families, or 583, reported unpaid bills. A little more than half owed \$100 or more. "By far the largest single item is for medical care."

How did these families live under such depressing circumstances? One man reported: "And so Sunday comes and we just sit." Thirty-eight per cent of the families said they had no recreation whatsoever. Many reported that they had not seen a moving picture for two, three, even four years. Trips and outings were no longer possible for the railroad employees, even though they had passes. Memberships in lodges, clubs, and churches were given up. Even social visits were out of the question, because the cost of refreshments for guests was prohibitive. Reading became a luxury.

The education of the children of these railway workers suffered markedly. One hundred and fifty-seven boys or girls either had dropped out of school or college or had deferred their entrance into the next higher course. One hundred and twenty-eight children had abandoned special instruction in music, drawing, dancing, and the other arts.

Two hundred and twenty-five families moved within four years prior to the time of the study, mainly to reduce rent. "Families accustomed to furnaces and hot-water facilities were living in 'cold flats,' often without electricity or running water. To give up inside toilets and baths, as many families had to, seemed like a reversion to barbarism."

These were the railway employees who suffered a 10% wage cut in 1932. Their incomes were further reduced by part-time employment.

That they went about improperly clad goes without question. "There comes a time when no amount of thought and care will revitalize old garments, when the important problems are warmth and decency. Many families of railroad workers had reached this point * * *. Many older children abandoned school because of shabby clothing. Parents confided that they had borrowed clothing in order to appear respectable at a child's graduation."

Wide-spread neglect of health met the eyes of the investigators for the Department of Labor. In 30% of the families one or more members required medical attention but could not afford it. Fifty-nine per cent of the families reported a need for dental care, and 26% of the families reported that at least one member needed eye examination or treatment. "Many families were reduced to monotonous and unhealthful diets * * *"

A study made recently by the United States Public Health Service of a group which like this had been reduced from comfortable to moderate or poor circumstances further illuminates the situation. Those who had dropped from "comfortable" to "moderate" incomes showed a rate of disabling illness 15 per cent higher than the "comfortable" group, which had suffered no reduction; and for those who descended from "comfortable" to "poor" incomes this rate was 60 per cent higher.¹ The chief significance of this report in connection with the railroad workers is that it reveals a close connection between illness and reduction in standards of living.

Summarizing the findings of this Department of Labor study of 1,000 railway workers during a depression, the author writes: "For these veteran railway men, in a well-organized and thoroughly regulated industry, the study records a slow retreat from relative security toward destitution."

With our economic machine stalled on dead center, it is little wonder that there is widespread unemployment in the railroad industry. The T. N. E. C. report to the President on July 14, 1939, that "evidences of the failure of the economic machine have not disappeared," could be repeated today with more emphasis. It is more true than ever, despite even the short flurry of unhealthy war trade, that:

People are still without jobs. Farmers are still without satisfactory markets. Industry is still without sufficient purchasers. We are still enmeshed in an economy the rate of growth of which is decreasing.

But besides general economic stagnation, there have been other factors making for unemployment in the railroad industry, among these being the loss of business to other forms of transportation; the abandonment of lines; technological changes; and the increased productivity of railroad labor.

Instead of enjoying the one-time virtual monopoly of freight transportation, today railroads perform about two-thirds of the freight service, and the balance is handled by highways, pipe lines, and waterways. Thus, while employment on steam railroads constituted 10.2 percent of the working force in 1920, it was only 7 percent in 1935.

The Interstate Commerce Commission reports that between 1921 and 1938, inclusive, class 1 railroads abandoned 8,067 miles of road and constructed only 2,811 miles, leaving a net decrease of 5,256 miles. Obviously such a deflationary program cut rather sharply into railroad employment.

PRODUCTIVITY OF RAILROAD LABOR

Mr. WHITNEY. There are numerous evidences of the increased productivity of railroad labor—a factor which has tended to aggravate the problem of unemployment. Before these are considered, however, let us note that, paradoxical as it may seem, unemployment itself has increased the productivity of railroad labor. Because of the application of the principle of seniority, employees with the least years of service are bumped first, with the result that the average years of service of those remaining on the job has a tendency to rise. Experience, measured by years of service, is closely correlated with efficiency,

¹"Comfortable" income is defined as that of \$425 and more per capita per year, "moderate" income as from \$160 to \$425, and "poor" income as less than \$150. U. S. Public Health Service: *Public Health Reports*, vol. 28, No. 41 (Oct. 13, 1933, p. 1261.)

and efficiency with productivity. In this negative sense, therefore, unemployment has increased the productivity of those remaining on the job.

How efficient is railroad labor? The answer to this question has been given by numerous investigators. For the purpose of this hearing, it should suffice to understand in general outline the extent of the rise in the productivity of railroad workers and some of the technological causes therefor.

The National Research Project of the W. P. A., which has been cited before, makes the following observations with regard to the productivity of railroad labor:

In terms of traffic units, the average output per work-hour increased from 109 in 1923 (on a 1920 base) to 128 in 1929, to 140 in 1933, and to 175 in 1936. This increased productivity of railroad workers was a result of the technical reconstruction of the railroads through managerial and mechanical changes, made possible by large capital expenditures during the period 1923-29 and through the further managerial changes made during the depression to reduce labor costs.

Increasing output per hour of railroad labor is not a new phenomenon. Output per hour nearly doubled during the first quarter of the present century. In 1900, railroad labor moved an average of 62 traffic units an hour, while in 1925, it moved 117. In the past, however, the growth of the volume of traffic was greater than the rate of increase of productivity, so that employment, too, continued to expand. After 1923, the rate of expansion of railroad traffic fell behind the rate of increase in productivity. Between 1923 and 1929, the average number of workers declined 11 per cent, the number of hours worked declined 13 per cent, railroad traffic increased by 3 per cent; productivity increased by more than 18 per cent. Between 1923 and 1936 the traffic volume increased by almost 43 per cent, but employment increased by only 3.3 per cent and hours of work by only 2.6 per cent; productivity per man-hour thereby increased 39 per cent.¹

With only slight variations, these findings are corroborated by data contained in "Exhibit No. 45," appearing on page 223 of part 1 of the hearings before this committee. In that exhibit output per man-hour on steam railroads is given for the following years:

(1923-25 AVERAGE=400)	
1914	75.3
1923	96.3
1929	113.8
1932	111.8
1936	140.4
1937	143.1

Witt Bowden, of the United States Bureau of Labor Statistics, found that "Productivity in terms of average output per man-hour worked in 1936 was 32.8 percent greater than in 1926, and 80.9 percent greater than in 1916." (Monthly Labor Review, July 1937.) This study has been discussed rather fully in chapter VI of the Brotherhood's book, *Main Street—Not Wall Street*—which was published in 1938 as a reply to the railroads' demands for a 15 percent wage cut.

It was found that the index of productivity of all employees is not materially less when based on hours paid for than when based on actual man-hours worked.

On the basis of transportation traffic units (a formula derived by the American Railway Engineering Association to measure operation and wear and tear of equipment), the increase in productivity of all

¹ Summary of Findings, March 1938, p. 111.

employees, excluding the principal salaried groups, increased 37.7 percent between 1926 and 1933, and 43.8 percent between 1926 and 1936.

I quote further from page 166 of *Main Street—Not Wall Street*:

Attention is called to the fact that in 1916 it required the services of 88,715 freight conductors and brakemen to move 362,444,397,129 revenue freight ton-miles, while in 1937 it required the services of but 60,455 freight conductors and trainmen to move 360,667,773,000 revenue freight ton-miles. In other words 28,260 fewer employees of these classes were required to move substantially the same amount of business.

Certain indices indicate the trend of productivity:

In 1920, as of December 31, the number of steam locomotives in service on class 1 railroads was 64,368; in 1926, 62,342; in 1938, 42,637.

But the average tractive power of steam locomotives in 1920 was 36,365; in 1926, 41,886; in 1938, 49,803—or an increase of 37 percent.

The average length of freight trains, including cabooses, was 36.6 cars in 1920; 45.2 cars in 1926; and 48.1 cars in 1938.

The average gross tons per freight train in 1920 was 1,443; 1,736 in 1926; and 1,895 in 1938.

In 1920 freight cars had an average capacity of 42.4 tons; in 1938 the capacity had increased by 16.5 percent, to 49.4 tons.

The average speed of freight trains between terminals was 10.3 miles per hour in 1920; 11.9 miles per hour in 1926; and 16.1 miles per hour in 1937.

The average speed of freight trains between terminals in 1939 was 62 percent greater than in 1920.¹

The speed with which passenger trains operate today is amazing. Between 1938 and 1939, the number of separate runs operating daily at 60 miles and more per hour increased from 864 to 997. American railroads now have 85 runs booked at 70 miles and more an hour. Contrast this with the year 1928, when, except for 1 or 2 short runs in New Jersey, there was not a single train in the United States scheduled to average more than 60 miles an hour.

Certain labor-saving devices and technological improvements have resulted in throwing railroad men out of work. Among these are the following: improved rails and tools—spike drivers, wrenches, drilling machines—the mechanical oiling of tracks; radical changes in the design of the steam engine; reduction in the number of manual block-signal stations; centralized traffic control; and automatic signal devices. Chemical treatment of railroad ties has doubled their life-span.

In discussing the matter of unemployment in the railroad industry, we cannot overlook the possibility that 200,000 to 350,000 jobs are at stake, should Congress adopt legislation calculated to open the flood-gates to widespread railroad consolidations. It is a known fact that the Wall Street interests that control the railroads would like to solve their financial problems by operating only the most profitable lines, abandoning the so-called unprofitable lines, and leaving in the wake of this destructive program many ghost communities and several hundred thousand workers without employment. Current railroad legislation before Congress, as embodied in the omnibus transportation bill (S. 2009), answers the problem for Wall Street.

¹ Source: Press release, Association of American Railroads, March 15, 1940.
124491—41—pt. 30—46

The Brotherhood of Railroad Trainmen, however, does not propose to acquiesce in such a vicious program. We have caused to be introduced what is known as the Harrington amendment to the omnibus transportation bill, which would offer complete protection to railroad labor in the event of the consummation of consolidation schemes. A large majority of the Members of the House of Representatives have declared themselves in favor of this amendment, as have thousands of citizens throughout the land who have signed petitions endorsing our proposal. Such wide support is indicative of a majority public opinion which says: "Congress must not pass any legislation which has the effect of destroying job opportunities."

At his inaugural on March 4, 1933, President Roosevelt said: "Our greatest primary task is to put people to work." I submit that the blackout of unemployment is still the first point on the Nation's agenda.

If we ponder the fact that the remarkable rise in industrial production which came at the end of the last year was accompanied by no appreciable rise in employment, then we shall begin to understand why we are now tobogganing downward at the fastest rate in history. The products of the machine are not bought by another machine. They are bought by employed people.

The usual question is asked of those who laboriously demonstrate the existence of unemployment, and the technological causes for it, as we have done today as respects the railroad industry: What do you offer as a remedy?

While I am not certain that it is possible to solve the problem in its entirety under our present economic system, which, in the last few years, has proved to be of more benefit to the profit takers than to the wage earners, we should nevertheless be able to take some steps that would alleviate the situation. The shorter workday is one such measure. Even the *Wall Street Journal* recognized this possibility when it declared, on February 3, 1940, that the ability of manufacturers to increase the number of their employees from December 1929 to December 1939, while there was a general 1-percent decrease in total employment, in a period "in which productivity of machines has increased as much as it has since 1929 is undoubtedly due to the reduction in the length of the workweek."

The 6-hour day should therefore be considered as an immediate and practical remedy for the problem of unemployment. Such a solution was urged in a resolution adopted unanimously on June 9, 1939, at the Second Quadrennial Convention of the Brotherhood of Railroad Trainmen, held in Cleveland, Ohio. This resolution embodied a comprehensive reemployment program for the railroad industry, advocating such measures as the shorter workday, rehabilitation of railroad properties, grade-crossing elimination, train limit and full-crew legislation. It is a clear-cut expression of the railroad worker's desire to see America free itself, in a democratic way and through peaceful means, from the economic dilemma with which it is confronted. The resolution follows:

REEMPLOYMENT PROGRAM IN THE RAILROAD INDUSTRY

Whereas the average employment of 940,000 workers on class I steam railroads last year was the lowest recorded for any year since 1899 and weekly wage payments to railroad workers in 1938 averaged 13 percent smaller than in 1937 and 41 percent below the 1929 average; and

Whereas the problem of reemploying tens of thousands of railroad workers who have been laid off in recent years, and the problem of promoting a high degree of safety in railroad operations are undeniably questions of first importance confronting railroad labor today; and

Whereas hundreds of thousands of railroad employees are anxiously seeking a solution to these problems in the form of a practicable program which will secure their jobs and incomes and reduce the hazards connected with this work; and

Whereas the Wall Street bankers who control the financial, and, therefore, the business, policies of the railroads have forced railroad management—often against its own better judgment—to curtail services, to lay off thousands of loyal employees, to attempt to slash wages, to allow equipment to deteriorate without adequate repair or replacements, thereby endangering the safety of the trainmen and the traveling and shipping public, in short, to carry through in the railroad industry the same policy of sabotaging the reemployment and industrial recovery program of the New Deal which the United States Chamber of Commerce and the National Association of Manufacturers pursue in other basic industries; and

Whereas this sabotage of our economic institutions is coupled with a diabolical attempt to strike at the political and economic liberties of the American people, so clearly evident in the Tory attacks on the Railway Labor Act, and efforts to destroy the principle of collective bargaining as embodied in the National Labor Relations Act; and

Whereas the preservation of democracy in this country demands a speedy bringing together of unemployed citizens and unemployed capital, to the end that this Nation may accomplish a complete economic recovery; and

Whereas the reemployment of men and money in the railroad industry would provide a great stimulus to the employment of idle labor and idle capital in all other industries, because the railroad industry is the very lifeblood of our economic system; and

Whereas this brotherhood—in fact, all railroad labor—has in the past recognized that the ultimate solution to the railroad problem lies in Government ownership and operation of the railroads; and

Whereas pending the attainment of this ideal, railroad labor must initiate practical steps to reinvigorate the industry: Now, therefore, be it

Resolved, That the Second Quadrennial Convention of the Brotherhood of Railroad Trainmen, while reaffirming the action of the previous convention with regard to Government ownership of the railroads—namely, empowering the president and the grand lodge officers to press for Government ownership at the most opportune time—does hereby go on record in favor of an immediate reemployment program in the railroad industry, sponsored by the Federal Government in cooperation with railroad management and railroad labor; and be it further

Resolved, That such a program shall embody the following minimum features: (1) The rehabilitation of railroad properties to the extent of several billion dollars in order to reemploy idle railroad workers, to increase the safety of the employees and the traveling public and shipping public, and to provide greater efficiency and speed. (2) The elimination of the many thousands of grade crossings. (3) The improvement of the conditions of railroad labor by (a) enactment of train-limit and full-crew legislation; (b) amending the Adamson 8-hour law to provide for the 6-hour day; (c) increasing the basic rates of pay; (d) reimbursing trainmen for away-from-home expenses; (e) securing vacations with pay; (f) liberalizing the disability features of the Railroad Retirement Act and giving credit for time spent in military or naval service; and (g) offering to every able-bodied railroad man a railroad job; and be it further

Resolved, That such a program shall be financed jointly by the Federal Government; by the State governments, insofar as the elimination of grade crossings is concerned; and by the railroads themselves, requiring them to reduce their capitalization and therefore, their debt burden; and that in extending reemployment loans to railroads, the Federal Government shall be given a voice in determining business and financial practices of these roads which shall be at least equal to the voice given the railroad banker; and be it further

Resolved, That the president of the Brotherhood and the national legislative representative be instructed to work for the enactment of Congress of legislation providing for the carrying out of such a program, and to invite all railroad labor to unite with us in backing up this practical program of reemploying idle men and idle money in the railroad industry; and be it finally

Resolved, That copies of this resolution be sent to the President of the United States, to the chairmen and members of the House and Senate Commit-

tees on Interstate and Foreign Commerce, to the railway labor executives, to the press, and printed in the forthcoming issue of the Railroad Trainman."

In conclusion, let me state that the logic, or rather the lack of logic, of the contention that technology does not reduce total employment opportunities is well illustrated by a pamphlet entitled, *Ten Facts of Technology and Employment*, published in 1936 by the Machinery and Allied Products Institute. I quote:

If technological advancement did not make possible a greater volume of production the standard of living could be raised only by increasing hand labor. Had it been necessary to increase hand labor in the same proportion as production between 1900 and 1930, every adult man and woman in the Nation and several million children would have been needed in jobs. It would have required more than 60 percent of the entire population, whereas only about 40 percent ever seeks gainful employment, the remaining 60 percent being constituted chiefly of women and children supported by the 40 percent.

Thus, the Machinery and Allied Products Institute started out to prove that labor-saving machinery does not destroy jobs and ended up by proving that were it not for machines and modern technology there would not be enough men and women workers in the Nation to accomplish the work now being accomplished with extensive use of machines and power.

That great American inventive genius, Thomas A. Edison, once said:

Human slavery will not have been fully abolished until every task now accomplished by human hands is turned out by some machine.

In the middle of the nineteenth century Dr. Ure, an expert English economist, advised the manufacturing classes of England that the goal of the manufacturers should be the development of machinery to the point where they could use the labor of women and children, which was cheaper than that of men, and that the ultimate goal was to displace all labor, as nearly as possible, through the development of the machine.

We should ponder the words of Dr. Ure in the light of the great increase in the industrial employment of women in this technological age. We should ponder Thomas Edison's words in the light of the dire consequences to human society. If Dr. Ure's goal should be achieved, the male portion of humanity would live only by the grace of employers and female income earners. If Mr. Edison's goal should be achieved, all of us would live, if at all, only by the grace of the machine owners.

And may I add one vitally important thought? He who considers that technological displacement of labor comprehends only the machine displacement of labor loses sight of a most important consideration. For the most part, in a machine age, the labor cost of making a product that will last for many years is no greater than the labor cost of making a product that has only a short period of serviceability. As competition and discovery force the improvement of products, a great displacement of labor thereby results. House paint that lasts for 5 years instead of 2½ years not only results in a 50 percent reduction in job opportunities for house painters, but there is a like reduction in employment in paint manufacturing, independent of the fact that machine methods of paint manufacture may also eliminate many workers. Likewise, with automobile tires that last for 30,000 miles, instead of 10,000 miles, storage batteries that last for 3 years instead of

1 year, and so on. Not only does such longevity of these products reduce by two-thirds the employment in their manufacture, apart from machine efficiency, but also such longevity greatly reduces the business opportunities of the cross-road garages throughout the Nation.

Gentlemen of the committee, we are face to face with the fact that the requirements of human existence cannot safely be left to the mercy of an unbridled private-profit motive.

Acting Chairman O'CONNELL. You will supplement this statement?

Mr. WHITNEY. With just a few highlights, if I may.

I might begin by saying that I would like also, if it is agreeable to the committee, to introduce a document entitled *Main Street Not Wall Street*, which was a portion of the *Brotherhood of Railroad Trainmen's case* before the 1938 President's Emergency Board in the wage controversy that was up at that time, and I would direct the committee's special attention to chapter 6, page 162, of that book, entitled "Productivity of Railroad Employees," which tells quite completely the statistical story of the productivity in our industry. I have only one copy today, but if it is desirable I would be glad to furnish a copy for each member of the committee.

Acting Chairman O'CONNELL. That will be accepted. Do you wish to substitute another copy for that one?

Mr. WHITNEY. No; the committee may have that copy, and I can furnish additional copies for each member of the committee.

Acting Chairman O'CONNELL. If you will make other copies available to Dr. Anderson, it will be appreciated.

Mr. WHITNEY. We will be glad to do that.

(The document referred to was marked "Exhibit No. 2635" and is on file with the committee.)

Mr. WHITNEY. My organization, I might say, has for a number of years been quite keenly aware of the problem you are discussing—technological displacement of workers. In March 1936 our official publication, the *Railroad Trainman*, published an article entitled "Machinery Creates Jobs—What of It?" I believe that has a lot of data that would interest this committee. I don't insist upon it, but if you are willing to receive it as an exhibit I should be glad to put that in also.

Acting Chairman O'CONNELL. How lengthy is that?

Mr. WHITNEY. It is four pages.

Acting Chairman O'CONNELL. Without objection, that will be accepted and printed in the record.

(The document referred to was marked "Exhibit No. 2636" and is included in the appendix on pp. 17434-17439.)

Mr. WHITNEY. That is a little more inclusive than just our testimony today because it covers the problem as a whole.

To highlight my president's testimony I might call your attention to a rather lengthy quotation from a study made by Mr. Carter Goodrich, of the United States Department of Labor, in May 1934, entitled "Earnings and Standards of Living of 1,000 Railway Employees During the Depression." The human considerations there are sufficient to move anyone to want to do something. It shows how railroad men descended, as it were, into the dark ages through having to give up all of their insurance, their standards of living, going together several in

one home, sacrificing their protection in the form of accident insurance, and all that.

That is a story which should move us all to deep consideration, but I would like the committee to read that bearing in mind also the businessman's viewpoint, the terrible deflation to business that comes to landlords and builders when people are thrown together several in one home. It seems to me that sometimes we become so deeply concerned with the human considerations of these things that we overlook that we are actually working against ourselves from a business standpoint in the deflationary effect upon our whole economy.

RAILROAD CONSOLIDATIONS

Mr. WHITNEY. Then I would like to move on to a consideration in our testimony which is very prominently before the country at this time, and that is a new technique for getting rid of labor and getting greater productivity—consolidations. I think we are pretty generally agreed that what we need in this country today is the employment of men and money, capital and labor. The outstanding characteristic of railroad consolidation, the very purpose of it, is to employ less money and fewer men, so it is of very genuine concern, it seems to me, to this committee, to ponder the possibilities of consolidations. We estimate that if a widespread consolidation program which would completely satisfy the ambitions of railroad bankers were put into force, at least 250,000 men would be eliminated in the railroad industry alone.

Mr. PIKE. From what sort of jobs would those people ordinarily come?

Mr. WHITNEY. I think it would affect all classes of railroad workers, from the engineer down. There would be fewer trains run, fewer train crews, tracks would be abandoned, there would be less maintenance work, and certainly the clerks would be greatly affected.

Mr. PIKE. That is what you usually hear, that there would be less work at the terminals and division points and things of that sort.

Mr. WHITNEY. Oh, yes, indeed.

Dr. ANDERSON. Of how much immediate concern is that problem of merging the railroads into a unified system?

Mr. WHITNEY. I was going into that. There is before Congress what is known as the Wheeler-Lea transportation bill, which admittedly was designed to facilitate and encourage consolidations. Our organization opposed that very strenuously because while there are many features of the bill we favor, we felt there was no law worth 250,000 jobs in this day and age of unemployment. I just want to call to your attention one of the prominent characteristics of our economy today, the tendency to pay men a pauper income for nonproducing. So economically unimportant has man's labor become that we have financiers actually willing in their desire for profits, to pay men to do nothing to get rid of the labor; that is inherent in the dismissal wage. Now we have never thought, as a social policy, of paying a group of bondholders a certain portion of their future worth to force them to surrender their bonds, but some seem to think that jobs and labor are less sacred. Therefore, capital proposes to pay men to take their jobs away from them and the

Brotherhood of Railroad Trainmen regards the dismissal wage as a relic of the dark ages. We believe that men should be entitled to work for a decent income and we don't believe they should be driven out of their jobs, especially when the reason for the dismissal wage is not improved service, it is not better incomes for workers, it is not lower rates to the shipper. It is to improve earnings to the bondholder, so we are absolutely opposed to the idea and the concept of a dismissal wage. We consider it a bribery offered to workers to surrender their opportunity to pursue their life's calling.

We introduced in the Congress, when we were threatened with this loss of 250,000 jobs, what is known as the Harrington amendment, which simply said to the railroads: "If you must consolidate, if you must make ghost communities throughout the land, you can't throw these men out overnight in mass numbers; you can't take the men of shortest periods of seniority and throw them into the bread lines. You will have to take care of them, and then you may take them off at the other end as they die, resign, or retire."

We consider that a very modest program. It does not offer much for the future in the way of increased employment, but at least it stops the crowding of bread lines in order to create better earnings and better profits.

I might tell the committee that we state in this document that 275 Congressmen signed a petition on behalf of the Harrington amendment, and we found an overwhelming majority of the Senators—in fact, only 1 Senator really opposed the idea of the Harrington amendment, so I believe that our Senators and Congressmen are becoming aware of the fact that disemploying men, for whatever cause, is not socially desirable. That was the full implication of the Harrington amendment, and, as I say, the dismissal wage is only a manifestation of the growing unimportance to profiteers of human labor.

I heard over the radio only Saturday a man speaking on behalf of the rural-electrification program, who said a farmer for a nickel could buy enough kilowatts to equal a full day's labor of a man, so that on that basis human labor is reduced to 5 cents a day. Now, if we are going to listen to the arguments that capital efficiency brought about this efficiency, that labor didn't bring this about, that labor should be paid what it is worth but no more, on that standard a farm laborer would be worth 5 cents a day.

RAILROAD FINANCES

Mr. PIKE. You don't think that capital isn't taking a spanking in the railroad business, too, do you?

Mr. WHITNEY. I don't know what you have reference to, but the thing that would loom in my mind would be \$100,000,000 lost in gambling in stocks and things like that.

Mr. PIKE. Another \$100,000,000 was used to extend the Chicago, Milwaukee & St. Paul to the Pacific coast, on which 98 percent is lost on today's quotations. You wouldn't call that gambling particularly.

Mr. WHITNEY. I am not particularly familiar with the financing shenanigans that went on in that case, but I do know the Chicago & North Western has been paid for two and seven-tenths times and still owes its average capital indebtedness.

Mr. PIKE. Yes; and the owner of those bonds hasn't received any income on his investment in some years. In the case of the Missouri Pacific, which sold common shares at \$100 a share, that is wiped out; in the case of the Rock Island a great many of its bonds are running around here at 5 to 20 cents on the dollar. I don't want to minimize your statement, but if there is any implication that capital hasn't been displaced by technology and other features in the railroad business, it is an entirely mistaken feeling. Its quoted value is about half of its stated value, though for purposes of the record I think the United States valuation showed very little water in the railroad business at the top, and whatever there was has been more than squeezed out by this deflation. The New Haven is another one which sold preferred shares at \$100 a share and during the last week the I. C. C. has said there is not enough left in the entire investment to deserve any consideration in the receivership.

I am not minimizing your story, but this technological change is not to the profit of the bondholders and the shareholders in the railroad industry. Everybody has taken a licking.

Mr. WHITNEY. I agree with you. I think we are just forcing ourselves up on a precipice to destruction. I think after the depression set in—I think I am correct on this—the railroads paid the highest dividends in history; they had such a momentum of big profits and big dividends that they couldn't stop, but, naturally, you have gradually washed up labor until now we are all upsetting the boat. I agree with that analysis of the situation very much.

Mr. PIKE. I think if you can point to anybody who foresaw where we would be in 1939 from the point of view of 1929, I believe we would like to have him appear before the committee.

Mr. MAGINNIS. Let me make this comment. Isn't the railroad industry the one industry that to common knowledge since the depression, in the last 10 years particularly, has been in terrible financial condition; and it is not due to technology, it is due to economics, isn't it?

Mr. WHITNEY. I have a friend, and I have never seen the time yet when he wouldn't take an hour off to tell me how busy he is. I sometimes think that about a lot of things we read in the newspapers about the railroads. When in a period of around 15 years the railroads can spend \$200,000,000 to tell you how poor they are, they are kind of like my friend who will take an hour out any time to tell you how busy he is.

Mr. MAGINNIS. Don't you think that is exaggerating it slightly?

Mr. WHITNEY. No; I do not. I am very sincere in making that statement. For instance, wouldn't you say any corporation that pays out more in dividends than it pays in wages is a pretty sound corporation?

Mr. MAGINNIS. What corporation does that?

Mr. WHITNEY. The Chesapeake & Ohio Railroad did that as recently as 1936, but that part doesn't get in the newspapers.

Mr. MAGINNIS. How many other railroads have been able to do it?

Mr. WHITNEY. I don't know that very many have. However, and this may shock you, but it is a fact, in 1931 and again in 1936 the Bessemer & Lake Erie paid 1,100 percent dividends.

Mr. MAGINNIS. What railroad?

Mr. WHITNEY. The Bessemer & Lake Erie.

Mr. MAGINNIS. That is a freight railroad.

Mr. WHITNEY. Sure.

Mr. MAGINNIS. In the steel industry.

Mr. WHITNEY. But when you talk about the abject poverty of railroads you are talking about certain railroads, not all railroads.

Mr. MAGINNIS. But you are talking about the railroad industry. Now, isn't it a fact that due to a great many conditions, including the economic conditions of the country during the depression period and the buses, the railroads have lost in revenue to such an extent that everybody knows that most of the railroads have been struggling against tremendous odds. The Interstate Commerce Commission has been trying to work out their problems to prevent more receiverships.

Mr. WHITNEY. What you say is true, but it can be said about other industries that we don't hear so much about. I read a piece about the railroad industry back in 1890, and I swear it sounded like the morning's newspaper. They were complaining then just like they do now.

Mr. PIKE. They were in trouble then.

Mr. MAGINNIS. They were in trouble then, but they didn't have the busses.

Mr. PIKE. They were in pitiful trouble then.

Mr. WHITNEY. Of course, but we understand there are conditions in the railroad industry that are serious. Any industry which can afford to waste \$1,000,000 a day must be in bad shape. Senator Burton K. Wheeler, after making a very thorough investigation of the railroad industry, solemnly announced that the railroads were wasting \$365,000,000 a year, \$1,000,000 a day. Now that, of course, we don't read about every day in the papers.

Mr. PIKE. That wasn't in wages.

Mr. WHITNEY. No; they haven't wasted a thing in wages; they are getting more now for their wage dollar than ever before in history. Whatever is wrong with the railroads, they can't lay it at the door of their employees, because the labor dollar today is worth more in the railroad industry than ever before in history.

Mr. CHANTLAND. Mr. Whitney, would you accept Mr. Pike's suggestion that the Rock Island and New Haven and that west coast extension of the Milwaukee are typical examples of good railroading and financing?

Mr. WHITNEY. Oh, not at all. I don't accept the statement either that our railroad industry is not overcapitalized. I still think there is a lot of water to be wrung out of the railroad industry.

If you read the history of the New Haven, it would put the Teapot Dome scandal to shame. I think that is the road that was mixed up in the Westchester, that spent \$1,500,000 a mile for the construction of the railroad. Well, when we go out on a drunk, we naturally have headaches afterward.

Mr. PIKE. That is gone, too.

Mr. MAGINNIS. That is water under the bridge, largely.

Mr. PIKE. I didn't mean to bring those up as cases of good judgment in the railroad industry at all.

Mr. CHANTLAND. I rather thought you did and I wanted to know if Mr. Whitney accepted those as good samples.

Mr. WHITNEY. Not at all.

Mr. PIKE. You can pick out a great many cases of bad judgment in the railroad industry, and I do think, though, that it isn't fair, that

when half the stated capital has gone in market quotations it is extremely probable from the evidence in hand of valuation that the waste has been eliminated and a great deal of the actual investment. It is particularly true in the case of that St. Paul extension; there was some funny business, in my opinion, on the bond financing, but the railroad was built, the money was spent on it, a great portion of it—perhaps there was a fair margin for what was regarded at that time as legitimate construction profit, but whatever money was put properly into that railroad at the time is gone. I think those St. Paul adjustments they were selling at one and a half the last time I looked at them, but they were the ones that finally came out of the Puget Sound extension. In the case of the Missouri Pacific—

Mr. CHANTLAND. Considerable was said about the cost of the receivership administration of the road, wasn't there?

Mr. PIKE. I think it is fairly true. Several insurance companies had a set-to over that.

Acting Chairman O'CONNELL. I think it might be well to let Mr. Whitney proceed. We are getting too far afield.

Mr. WHITNEY. I don't want to pose as an expert in railroad financing. I think to clear the record, though (I thought I heard you say the waste had been eliminated), it should be said that only a little over a year ago Mr. Wheeler made the statement that the railroads were wasting \$1,000,000 a day.

Mr. PIKE. I didn't mean waste in operation, I meant in original construction that had probably gone out the window in the decline in quotation of bonds or lack of unearned interest. That money has proved to be wasted by the fact that it didn't earn enough to pay its board. I didn't mean the annual day-to-day waste.

Mr. WHITNEY. Just the other day I read a statement that the railroads overpay on supplies purchased, through favors to shippers, and that they could save \$100,000,000 a year on purchases if they got value received, as you and I are supposed to when we buy.

Acting Chairman O'CONNELL. Can you tell me where the Wheeler-Lea bill is now?

Mr. WHITNEY. It was just reported out. The conferees announced that they agreed Friday night.

Acting Chairman O'CONNELL. Did they include the Harrington amendment?

Mr. WHITNEY. I am sorry to say they didn't. They struck out the entire consolidation section of the bill, dealing with the facilitating and expediting of railroad consolidation.

Acting Chairman O'CONNELL. There is really no point to the Harrington amendment without the consolidation?

Mr. WHITNEY. The Harrington amendment was conceived because of this threat of facilitation of consolidations.

Of course, I can't too strongly urge the necessity for shorter work hours as one means of meeting this problem.

Dr. ANDERSON. In that connection, I have just received a distribution of working time from Dr. Parmelee, in response to our request. That statement indicates that a very substantial proportion of all railroad workers now work very brief hours, which would not permit reducing their hours any further; many of them were employed for a few days in less than 2 months of a year. You weren't talking about reducing hours for such part-time employed workers.

SIX-HOUR DAY

Mr. WHITNEY. Absolutely not. I mean reducing a normal month's work without any reduction in pay, in other words, making the standard day of work 6 hours instead of the present 8 hours.

Dr. ANDERSON. And how would you cover the increased costs of such a procedure?

Mr. WHITNEY. Well, I sometimes think there are a lot of great economic truths which cannot be stated in terms that an economist would understand. I refer, of course, to the so-called "expert" economists who write for the financial pages of newspapers.

What I mean by that is this: in 1932 the railroads asked us for a 10-percent deduction in pay rolls. They solemnly told us that if we would take that 10-percent deduction for 1 year only—that is all they were asking for, and they emphasized that—it not only would solve the problems of the railroad industry but would restore national and world prosperity. Of course, that made us feel pretty important, and in our weaker moments we accepted the 10-percent cut, although our organization never felt that it was good for the country or the industry. In 1 year that deduction, I think, took something like \$24,000,000 out of the purchasing power of the Chicago area alone.

You asked about the increased cost. This supposed reduction in cost meant a net increase in costs, because it didn't help the railroad industry. The industry got worse, and the country got worse, and it certainly didn't solve the problem of world prosperity. I think as we distribute wealth through shortening hours and dividing up the work, we don't decrease costs on an economic basis, because the social values far outweigh the economic costs. Most economists would want proof of that generalization. However, I believe observation indicates that the natural consequences of constant deflation are more costly, even to the businessman, to say nothing of society, and it seems to me that that is the answer. We can do more work today in 6 hours than we could in 10 or 12 hours back in 1910.

Acting Chairman O'CONNELL. But assuming that the railroads are in general in a rather bad state, in part because of attempting to meet competition from other areas, as a practical railroad man I am afraid it would be a little bit difficult for him as a businessman, looking at his costs, to take the long-run view, as an individual, that a reduction in his wages is going to decrease mass purchasing power and is going to be part of a deflationary spiral which will make him worse off in the long run, because he is confronted with the day-to-day situation of meeting competition. While I would be inclined to agree with you on the social desirability of the long-range policy, most businessmen today confronted with the problem of making money are not so apt to take that broad view.

Mr. WHITNEY. I think that is very true. I don't think you can point to a thing in our industry, whether it be shorter work hours or increased wages or safety legislation, that the railroads haven't solemnly predicted it would bankrupt the industry. The Safety Appliance Act, which was designed to save the lives and limbs of working men, was hotly argued against as being a device that would completely bankrupt the railroads. We have grown in social conscience, and we haven't bankrupted anybody. Where we went bank-

rupt is when we let millions of people go and destroyed their purchasing power. That is what bankrupts us all.

Mr. MAGINNIS. Mr. Whitney, your remark about dismissal wages as being a form of bribery to the employee, isn't it a fact that every other industry, or we will say most of the other industries, in trying to meet the changing situation of progress and technology are working for that very thing of having some sort of a system of dismissal wages or displacement wages, which you term bribery?

Mr. WHITNEY. If you are talking about the legal definition of bribery, it obviously isn't.

Mr. MAGINNIS. I don't mean legal definition, I mean as a characterization.

Mr. WHITNEY. It is an inducement to a man to part with his job, without knowing what you are going to do with him after you get him separated from his job. I am condemning the social conscience which builds up these mechanisms designed to offset the economic cheapness of human labor, the change from the days of the wilderness, when probably all economic production was 95 percent human labor, to now, when it is 2 or 3 percent human labor. When you give a man a dismissal wage, and separate him from his job, have you solved anything? Haven't you only aggravated the problem?

Mr. MAGINNIS. But if a certain railroad, being operated in a businesslike manner, finds that the economic conditions in the territory in which that railroad is operating are such that its revenues are not keeping up to operating costs, would you argue that rather than cut down on the operating costs, even to the extent of letting some of the men out, that it wouldn't be better to keep that road in operation, than to try to get the I. C. C. to let them abandon the road completely?

Mr. WHITNEY. Of course, that is the threat that the railroads constantly hold over us. "If you don't do something here, we are going to abandon, and you will lose all your jobs."

DISPLACEMENT AS A RESULT OF CONSOLIDATION

Mr. WHITNEY. That was the argument for the Wheeler-Lea bill. It was argued on the floor of the House, "If you boys will just give up 250,000 jobs everything will be rosy, and in the end you will have more jobs than if you gave up none." That just doesn't appeal to me. The way the banker and the butcher and the candlestick maker get more is by getting more, but railroad employees are supposed to believe that by giving up a large part of what they have they will get more. I don't believe that.

Mr. PIKE. Do you use that 250,000,000 pretty accurately?

Mr. WHITNEY. Two hundred and fifty thousand.

Mr. PIKE. I had three too many ciphers on it. I was trying to remember the figure they gave us the other day of those working in the railroads. As I remember, it was just about a million or a little under. If my memory is correct, that would mean a quarter or more of all railroad employees displaced under such a bill.

Mr. WHITNEY. That is right.

Mr. PIKE. I think that would require some demonstration to me.

Mr. WHITNEY. I can demonstrate to you in just a moment. I have been arguing it for the last 2 months, so I have the data at my fingertips, fortunately. In the first place, the Prince plan, which was advo-

cated about 4 years ago and which didn't depend upon any enabling legislation at all, as I understand it, proposed to eliminate one-third of the railroad employees. The *Wall Street Journal*, I think, on January 17, 1940, said that if they could get this enabling legislation they could look forward to saving \$500,000,000 annually through railroad consolidations.

President Daniel Willard, of the B. & O., says that in consolidations 80 percent of the savings come from labor. Well, 80 percent of \$500,000,000 would be \$400,000,000. You are going to eliminate the lower-paid groups, mostly. But, let's say the average elimination will be of men who have \$1,000-a-year jobs. Four hundred million dollars would eliminate 400,000 jobs, so I am basing my estimate on Wall Street's ambition. I don't say it will be 400,000 jobs. I believe Mr. Willard included in his 80 percent some indirect labor, so it seems to me that 250,000 or 225,000 is rather conservative.

Mr. PIKE. We just don't see along the same line. I was trying to see where the consolidations of corporations would have that effect. I would see a few runs eliminated where there are now, say, competing runs not doing very much business, but I can't get the mental picture of more than a quarter of the railroad employees being eliminated. I don't take your demonstration as a complete demonstration. You have taken one quotation from one source and another from another and come to a conclusion that I still don't quite feel can be warranted.

Mr. WHITNEY. Are you familiar with the Prince plan of railroad consolidation?

Mr. PIKE. That this Chicago fellow put out a few years ago?

Mr. WHITNEY. He is a Boston banker.

Mr. PIKE. I think it was the same man.

Mr. WHITNEY. Mr. Prince boldly admitted that his plan would eliminate one-third of the employees, so I have pretty good authority back of me. I am telling you what the ambitions of the railroad bankers are. I am not admitting that we will ever consent to the elimination of that many.

Mr. PIKE. You are not going to stand for it?

Mr. WHITNEY. Consolidations offer one very interesting aspect. They are the one thing that brings organized labor and the chambers of commerce together. When we have a threat of a railroad consolidation, the chambers of commerce all along the line threatened with elimination join hands with us, and we raise so much trouble about it that the Interstate Commerce Commission is convinced that it isn't a good thing, and they don't approve the consolidation. I am not admitting that we are going to lie down and let them eliminate 250,000 men, but I am saying that is the ambition of the men who pretty largely determine the destiny of our economic system.

Mr. MAGINNIS. That may be a plan, but it is a long way from being carried out, a consolidation plan of that size, don't you think?

Mr. WHITNEY. I would feel a lot happier about your prediction if you were a railroad banker, because I know what their ambitions are, and I know that they want to do that. Whether they can do it is a question of how much we will protect ourselves.

Mr. PIKE. I will put it to you this way, that not one of the railroad

consolidations put through during the twenties eliminated anywhere near that proportion of men from the railroads involved.

Mr. WHITNEY. You bring up another question that is very important and that probably should be answered, if we aren't getting too far from the subject.

Mr. PIKE. This is the subject, this elimination of men. We are not going far from the subject.

Mr. WHITNEY. If you read the hearings and testimony and the argument before the Senate, including the speech of Senator Cummings himself, at the time of the enactment of the 1920 Transportation Act, you will find that the purpose of consolidation then was entirely different from the purposes now hoped to be achieved. I understand that since 1920 some two hundred railroads have been consolidated, which is apparently what you have in mind.

Heretofore consolidations in the railroad industry have been what is called end-to-end consolidations, the completion of lines, the throwing of two partially complete routes together. The whole purpose of the consolidation section of the 1920 act was not to eliminate men, or even to achieve economy. The word "economy" was not even mentioned in connection with it. The whole idea was to establish rates which would give a fair return to the railroads. They had a very mean problem, which still exists today, which accounts for the huge dividends of the C. & O. and Pennsylvania and some of the other big roads. Their problem was this: If they fix a rate low enough to make a fair return to the C. & O., it will be so low that the struggling roads can't live on it.

On the other hand, if they make a rate high enough for the weak roads, then the Chesapeake & Ohio and the Bessemer and Lake Erie will pay huge dividends, and the returns would be unconscionable. So, they said, "The way to solve this problem is to even the thing out by having the strong roads absorb the weak." Now, of course, it was placing too much faith in railroad bankers to assume that they would ever go around and pick up these poor-paying roads and consolidate them, so nothing has happened and we haven't had many major consolidations since the 1920 act went in force. But now we come along with a law where the whole idea is not to consolidate the weak with the strong but to consolidate for improved profits. Now, that is a major change in the purpose. I think if you will give that a little thought, you will see that when the whole purpose of consolidation is economy, you will get a greater elimination of men than when the purpose of consolidation is to complete routes or make the strong and weak come together.

Mr. PIKE. There is certainly something in what you say.

Mr. WHITNEY. I want to make just 2 or 3 more points. I might call your attention to an article entitled "Ten Facts on Technology and Employment," published in 1936, by the Machinery and Allied Products Institute. I won't read that quotation, in order to save time, but the rather humorous part of that pamphlet is this. They started out to prove that machines do not destroy jobs, and they ended up by proving that if it were not for machines and power there wouldn't be enough men, women, and children in the whole Nation to fill the jobs that would be required. To me that represents the lack of logic of the contention that machines do not eliminate jobs. Then, I want to call to your attention that Thomas Edison once

said, "Human slavery will not have been fully abolished until every task now accomplished by human hands is turned out by some machine." And way back in the middle of the 19th century, Dr. Ure, an English expert economist, advised the manufacturing classes of England that the goal of manufacturers should be the development of machinery to the point where they could use the labor of women and children, which was cheaper than that of man, and that the ultimate goal was to displace all labor as nearly as possible through the development of the machine.

Now, gentlemen, if we have in mind Thomas Edison who said all work should be done by machines, and bearing in mind the great growth of women in industry, we can see the tendency pointed out by Dr. Ure in the middle of the 19th century, and we are brought to the conclusion: How are we going to live if a few people own our natural resources and a few other people own our machines and machines do all the work or most of it? We will be living pretty largely by the grace of the few owners. I think that is a very serious matter.

Another point that I want to impress upon you is this: Most people think of technological displacement of labor in terms of the machine. I would say that is only a small part of the problem. The improvement in products, for instance, paint which lasts for 5 years instead of 2½ years—what does that mean? It displaces men who manufacture the paint, it displaces house painters, and it displaces transportation workers, and so on. Bear in mind that the improvement in the quality of a product does not necessarily call for greater labor cost. For instance, I think for a pair of pliers that you buy in the 10-cent store the labor cost is about the same as if you got a good pair of pliers that would last a lifetime. As invention and discovery force us into better and better products, that in itself will probably eliminate more jobs even than the machines as such.

You know there is a tendency to bring the manufacturing centers closer to the point of consumption, to spread out Mr. Ford's idea. What is that going to do us railroad workers? Naturally, it is going to mean less transportation.

Finally, most all industries have a great increase in productivity with a very small increase in labor. It doesn't take any larger train crew if the passenger cars are filled or if the freight cars are filled than if they are partially filled.

I don't want to be too much of a pessimist here today. I heard a story the other day that said the difference between an optimist, a pessimist, and a skeptic was well illustrated at the breakfast table. The optimist says, "Please pass the cream." The pessimist says, "Pass the milk." The skeptic says, "Pass the pitcher." I am asking that we pass the pitcher. I think these are problems that we have just got to do something about. I am not a pessimist. I think they can be solved, but I think they are ominous, to say the least.

Acting Chairman O'CONNELL. Have you any further questions?

Dr. ANDERSON. No.

Acting Chairman O'CONNELL. Thank you very much, Mr. Whitney, for coming. We will recess until tomorrow at 10:30.

(The witness, Mr. Whitney, was excused.)

(Whereupon, at 4:35 p. m., the committee recessed until 10:30 a. m., Tuesday, April 23, 1940.)

INVESTIGATION OF CONCENTRATION OF ECONOMIC POWER

TUESDAY, APRIL 23, 1940

UNITED STATES SENATE,
TEMPORARY NATIONAL ECONOMIC COMMITTEE,
Washington, D. C.

The committee met at 10:40 a. m., pursuant to adjournment on Monday, April 22, 1940, in the Caucus Room, Senate Office Building, Representative Clyde Williams, Missouri, presiding.

Present: Representative Williams (acting chairman), Senator O'Mahoney (chairman), Messrs. O'Connell, Pike, Lubin, and Brackett.

Present also: William T. Chantland, Federal Trade Commission; S. Abbot Maginnis, Department of Justice; and Dewey Anderson, economic consultant to the committee.

Acting Chairman WILLIAMS. The committee will be in order, please.

Dr. ANDERSON. Mr. Chairman and members of the committee, we are beginning today two important days of hearings on the subject of employment in agriculture and the whole broad field of agriculture. Today's witnesses are from the United States Department of Agriculture, and together they form a panel which will attempt to present the range and scope of this problem. In working out the testimony with each other they have split it up into parts, each man appearing in the field in which he is expert. It is hoped that it will be possible for them to present their testimony without too much interruption. They will all be present after that for the questioning of the committee, but I know we will expedite matters greatly if we can proceed in that way.

The experts to be heard are Dr. Carl Taylor, of the Division of Farm Population and Rural Welfare, Department of Agriculture; Mr. Ernest Holcomb, who is reading Dr. William T. Ham's paper (he is of the Division of Farm Population and Rural Welfare); Dr. Sherman Johnson, Division of Farm Management and Costs of the Department of Agriculture; Dr. Louis Bean, economist, of the Bureau of Agricultural Economics of the Department of Agriculture; and Dr. Norman Wall, Division of Agricultural Finance, of the Department of Agriculture. It is presumed that they will take the day for their testimony.

The first witness this morning will be Dr. Carl Taylor, followed by Mr. Ernest Holcomb. I would suggest swearing both witnesses at the same time.

Acting Chairman WILLIAMS. Will you be sworn, please? Do each of you solemnly swear the testimony you are about to give in the matter now pending shall be the truth, the whole truth, and nothing but the truth, so help you God?

Dr. TAYLOR. I do.

Mr. HOLCOMB. I do.

TESTIMONY OF DR. CARL TAYLOR AND ERNEST HOLCOMB, DIVISION OF FARM POPULATION AND RURAL WELFARE, DEPARTMENT OF AGRICULTURE, WASHINGTON, D. C.

Dr. ANDERSON. Might we have a brief résumé of your professional experiences and background to determine your competency as witnesses in this particular testimony?

Dr. TAYLOR. Well I was born and reared on an Iowa farm. After going through college I taught in the Agricultural College until I came to the Department here in Washington. I taught at the University of Missouri and the North Carolina State College of Agriculture and came here with some of the newer agencies and for the past 5 years I have been head of the Division of Farm Population and Rural Welfare.

Dr. ANDERSON. Dr. Taylor, you have published works in this field?

Dr. TAYLOR. Yes.

Dr. ANDERSON. Will you give us some indication of its character?

Dr. TAYLOR. I have a book on rural sociology which is just a textbook. I have a number of pamphlets, experiment-station pamphlets, having to do with farmers' organizations, community organizations, and so on.

Dr. ANDERSON. And scientific organizations?

Dr. TAYLOR. Yes.

Dr. ANDERSON. Mr. Holcomb, what is your professional background?

Mr. HOLCOMB. I was reared in Texas on a small poultry farm and educated at the Texas Agricultural and Mechanical College and have been with the Department of Agriculture for the past 4 years. Prior to that I worked at an experiment station in Texas.

Dr. ANDERSON. We will proceed with Dr. Taylor.

Dr. TAYLOR. I think Mr. Chairman, I will read a short statement, to give a sort of background for all the testimony that will be presented during the day.

TECHNOLOGY IN AGRICULTURE

Dr. TAYLOR. The information to be presented here has to do with the development of science and technology in farming, and their influence upon efficiency in production, employment, population movements, and the capital debt structure in agriculture. The story in brief consists of:

(1) an increasing efficiency in the production per man in agriculture, but a steadily diminishing opportunity for employment on farms;

(2) an increase in out-of-pocket and fixed costs of farm operations, and an increase in the economic risks involved in farming, due to expenses incurred in the purchase and operation of machinery, and interest charged for debts and tax services;

(3) an increase over several decades in the farm-mortgage debt in relation to farm values, resulting in a decreasing percentage of farm real-estate equities owned by those who till the soil:

(4) a cityward movement of farm population during periods of prosperity, and a tendency of this movement to reverse itself during periods of depression, which has resulted in recent years in the accumulation of a great surplus of persons of working age in the farm population;

(5) a fairly steady shift from owner to tenant operated farms since 1880, resulting in an ever-increasing number of persons in agriculture occupying the lower rungs of the agricultural ladder;

(6) an increasingly larger share of farm income now spent for farm implements and machinery and for their operation, which contributes to the rigidity of the farm operating cost structure and the disparity of farm income and parity income, and increases the competition between operating costs and farm family standard of living;

(7) a sizable shift in the ownership of farms from farmers to centralized lending agencies in satisfaction of debts, and an increase in the proportion of farm-mortgage debt held by the centralized lending agencies; and

(8) the effect of these trends to technological developments is seen in part in a somewhat different distribution of the number of farms in relation to size and to income. In a number of types of farming, we now have a somewhat larger number of small-sized farms and a more marked increase in the relative number of large-sized farms. Similarly, we now have a relatively larger proportion of income in the relatively low-income brackets, and marked increases in the proportion of income in the farms of the highest-income brackets.

That is an attempt to give a sort of over-all of the testimony to be presented during the day.

My particular part of the testimony has to do with the population movements, unemployment in agriculture, the increase in percentage of farm people who are in the working-age group.

The first chart that is before you presents the shift in the percentage of gainfully employed between the different occupations of the Nation, and shows a steadily diminishing percentage of all gainfully employed who are occupied in agriculture.

Acting Chairman WILLIAMS. It may be received.

(The chart referred to was marked "Exhibit No. 2637" and appears on p. 16924.)

Dr. TAYLOR. This chart gives information from 1870 to 1930. I don't think I need to say much about it because it is pretty graphic in its display, but the percentage of the total gainfully employed in the nation who were employed in agriculture fell from about 53 percent in 1870 to about 21 percent in 1930. This was undoubtedly chiefly due to the shift to urban centers of many occupations and processes at one time carried on on the farm: canning, smithing, milling, and things of that kind, to a point where a great deal of canning and even bread making and things of that kind have shifted into the city.

The occupations which picked up the losses in gainfully employed from agriculture during this period were manufacturing and mechanical pursuits, which picked up steadily until about 1910, but have held about steady since 1910, the domestic, professional, governmental services of all kinds, and the trade and transportation and finance group, which is in those groups at the top, which increased from around 25 percent of all gainfully employed in 1870 to about 38 percent now.

The next chart simply takes that agricultural block and projects it by estimation from 1930 to 1940, although the estimation is not complete because it is now 1940.

(The chart referred to was marked "Exhibit No. 2638" and appears below.)

Dr. TAYLOR. During that period the decline has been stayed, due to lack of opportunity for rural born and reared people to continue to shift into urban industries. The percentage, therefore, in 1940 is pre-

WORKING POPULATION IN AGRICULTURE, PERCENTAGE OF U.S. TOTAL, GAINFUL WORKERS 10 YEARS OF AGE AND OVER

sumably about the same, 21 percent as in 1930, but of course the increase in population makes that a considerably greater number of people. I have not attempted to estimate just how many those people were. It simply tells the story that over a long period of time there has been a steady shift of the people of employable age out of agriculture into urban industries.

The next chart is Movement to and From Farms, 1920-38.

(The chart referred to was marked "Exhibit No. 2639" and appears below.)

EXHIBIT No. 2639

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

MOVEMENT TO AND FROM FARMS, 1920-38

BIRTHS AND DEATHS NOT TAKEN INTO ACCOUNT

Dr. TAYLOR. That shows the story for the last 20 years of that movement of population, presumably either attracted by opportunities for employment in cities or pushed by lack of opportunity on the farms. The lower block of the chart shows the movement annually from 1920 to the end of 1938 (the estimates for 1939 are going through the mill at the present time) of the people who left cities to return to farms; there is a constant movement back and forth from farms to towns and cities and from towns and cities to farms. The upper curve, the one running from the bottom of the chart to the top, represents people who move from farms to cities, and the mottled section of the chart between the two curves is the net movement. You can see that for most of the period there has been a net movement of population from farm to city. Between 1922, which is the first high point in the top curve, and 1926, which is the second high point in the curve, there was a net movement; that is, there were 3,480,000 more people, or more moves, from the farm to the city than there were back, leaving a net migration to cities from farms during that 5-year period of 3,480,000. That was a period of relative urban prosperity, and I think you may safely conclude that was largely the reason for the great flow from the farms to the cities. From 1926 until 1932 there was an almost steady decline annually of the people flowing from the farms to the cities, with the result that in 1932, the only year of which this was true,

there was a net flow back to the farm. Taking the 5-year period preceding 1932, there was a net flow of 1,588,000, or less than half what there was in the first 5-year period; in 1932, at the depth of the depression, there was a net movement of 266,000 people back to the land from farms and cities. In 1933 there were 318,000 moving in the other direction, so 1932 and 1933 approximately balanced each other for that period.

Then take the 5-year period since that time: there has been a movement back to the city again, fairly steady, but you will see that it has not been as great in the last 2 years as it was in the 2 years preceding that. The net movement from farms to cities in the 5-year period since 1933 is about 1,604,000, or about \$320,000 per year. This movement, as you can see, is not a depression phenomenon. The shift back and forth is something that is going on in our national life all the time, and yet I suspect we can draw the conclusion that it does vary with the opportunities for employment in agriculture as contrasted with those elsewhere, except that when both agriculture and industry are down there seems to be a tendency for the people to seek shelter on the land.

The next chart is, Estimated Rural-Farm Population 15-64 Years Old.

(The chart referred to was marked "Exhibit No. 2640" and appears below.)

EXHIBIT No. 2640

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

ESTIMATED RURAL-FARM POPULATION 15-64 YEARS OLD, 1920-60
(ASSUMING THAT MIGRATION AFTER 1930 IS HALF AS GREAT AS BETWEEN 1920-30*)

BASED ON ESTIMATES OF FUTURE POPULATION BY STATES, NATIONAL
RESOURCES BOARD, WASHINGTON, D. C., 1934

U. S. DEPARTMENT OF AGRICULTURE

BUREAU OF AGRICULTURAL ECONOMICS

LABOR FORCE ON THE FARM

Dr. TAYLOR. This isolates the working-age group in the farm population and shows you the trend in numbers of those people, that is

people from 15 to 65 years of age. That doesn't mean that no one works on a farm before he is 15 years of age and that everyone quits at 65, but we use census data and say those of working age are from 15 to 65. You have a regularly increasing number of people in this group, because the migration to the city has slowed up, reversing itself in 1932, and recovering a little less than half the migration of the twenties, and because of the number of births in the farm population. That rural birth rate feeds a great many more people into the lower end of the age limit than move out at age 65, so the number of people in this group constantly increases.

That chart is projected to 1960, two decades in the future.

That is not a very wild guess, because all the people who are born in 1940 or before 1940 are now in existence and therefore the youngest of them will be 15 years old in 1955, so you don't have to guess on how many of them are going to be born. All you have to do is to take the mortality rates and the expectancy of deaths, and your calculation is pretty safe as to how many of those people will have reached 65, or 64, and so on down, because they are all in the population at the present time.

If the amount of migration from farms to cities which prevailed in the twenties, when in 1 year over a million net moved into the cities off farms, were to take place again, our farm population would gradually diminish, as it did fairly steadily between 1910 and 1930. It was about 1,900,000 less in 1930 than it was in 1910 because of this cityward migration. If that happened, our farm population by 1960 would fall to about 29,000,000. There is no evidence, however, in the present trend that it will fall that rapidly. On the other hand, if we were to have the phenomenon that we had in 1932 and 1933, when there were just about as many people coming back from the cities and towns as went into the cities and towns, and the farm population retained all of its natural increase, we would have about 45,000,000 in the farm population by 1960. We undoubtedly have today the largest farm population we have ever had because of this increase since the depression. So taking the migration from 1930 to 1940, which you saw in Exhibit No. 2639 was around 300,000 a year, or assuming that the migration in the next two decades will be one-half of what it was between 1920 and 1930 (and that is higher than it is running at the present time) we would then probably have in 1960 37,500,000 farm population.

I think I had better read the last paragraph of the explanation that you have before you.

Should the rate of net migration away from farms during the next two decades (1940 to 1960) be half as great as during the pre-depression decade of the 1920's (and half is considerably above the rate during the decade of the 1930's), the increase in farm population (by 1960) will be 16 percent, or 5,000,000 people.

Now because most of the people are in the age group from 15 to 65, 4,000,000 of those people would be in the working-age group, so we would add to the people now seeking employment in agriculture about 4,000,000 more people trying to find the way to make a living in agriculture.

The next chart shows that a little more graphically.

(The chart referred to was marked "Exhibit No. 2641" and appears on p. 16928.)

Dr. TAYLOR. The block to the right shows the male farm people of working age and the one to the left both male and female. The story of that chart is a continuation of the one which I just mentioned, that we have a steadily growing number of farm people of working age in agriculture.

And that number is far greater than the number needed to replace the people who die in agriculture, and far greater than the number needed to displace or to replace all the farmers who reach 65 years of age, if all of them quit farming at that age, so on the right-hand block even assuming that all farmers will retire at 65—and they won't—and that they have the normal death rate according to the experience tables of the life insurance companies, you will have

EXHIBIT No. 2641

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

RURAL FARM POPULATION: TOTAL ENTRANTS TO AGE GROUP 15-64, 1930-40

U. S. DEPARTMENT OF AGRICULTURE

BUREAU OF AGRICULTURAL ECONOMICS

1,886,000 boys in the farm population either hunting for opportunities to migrate into other enterprises or piling up on the farm trying to make a living there.

Now the last chart, which is a map.

(The chart referred to was marked "Exhibit No. 2642" and appears on p. 16929.)

Dr. TAYLOR. There are two maps, in fact, but this one is the important one. It is an attempt to get some judgment on what sort of an economic environment these 1,886,000 boys coming on in the farm population have. That doesn't assume that anybody is moving out from the city, but includes only boys who are on the farm now, who will graduate at 15 years of age. What sort of economic environment they are going to face, as best we can calculate? Those data are from the Unemployment Census, and with your permission I will read the page here, because while we may not know exactly how to interpret these as we project them into the future, they

present a pretty serious problem. This increased farm population of working age is not only confronted with the lack of farms to which to go, and a not too rosy picture from the standpoint of farm income, but they are immediately thrown into competition with a lot of people out there who are already unemployed. In the face of an almost certain increase in the number of farm-born persons seeking employment in agriculture, there is a great volume of unemployment already existing on farms. In 1937, according to the Unemployment Census, 1,547,000 males living on farms were either totally or partially unemployed, or had only emergency employment.

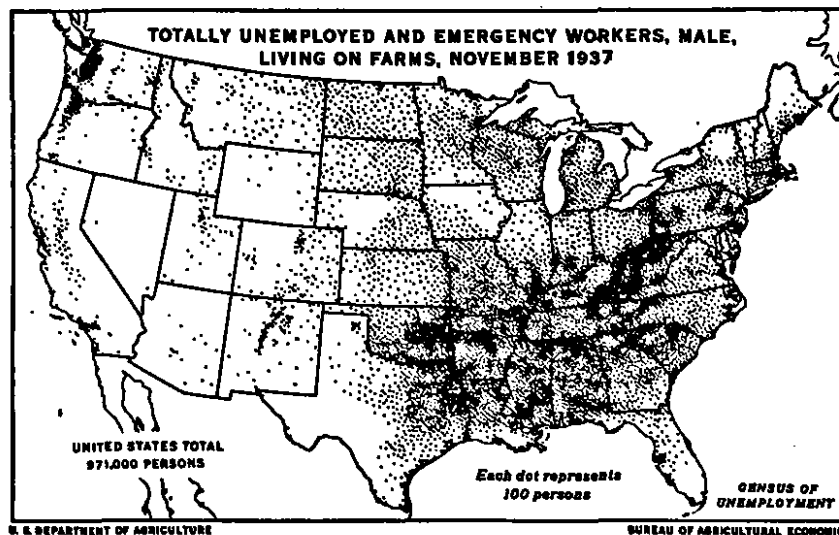

Acting Chairman WILLIAMS. At what age, just in that connection?

Dr. TAYLOR. That age, again, was, I think, 15 to 65, or was it 18 to 65? I think it was 15 to 65.

Of this number, 576,000 were partially employed and 266,000 were employed in emergency public works—W. P. A., C. C. C., N. Y. A., and so forth; the remaining 705,000 were totally unemployed.

EXHIBIT No. 2642

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

Unemployment on farms is not entirely due to the economic depression but in part to a combination of long-time trends. As has been noted, the proportion of the total gainfully employed in the Nation who were employed in farming declined at an almost constant rate from 1870 to 1930, but during this period the increase in nonfarm employment created opportunities for those not needed in agriculture. The result was a net migration from farms to cities, which reached a maximum of 500,000 to 1,100,000 each year from 1922 to 1926. This annual net migration now is only a little more than 300,000 per year.

In other words, as these people came on in the past they found an opportunity to leave the farm and find employment elsewhere. But that is not true now—neither the migration flowing to the cities as it did and unemployment piling up on the farm.

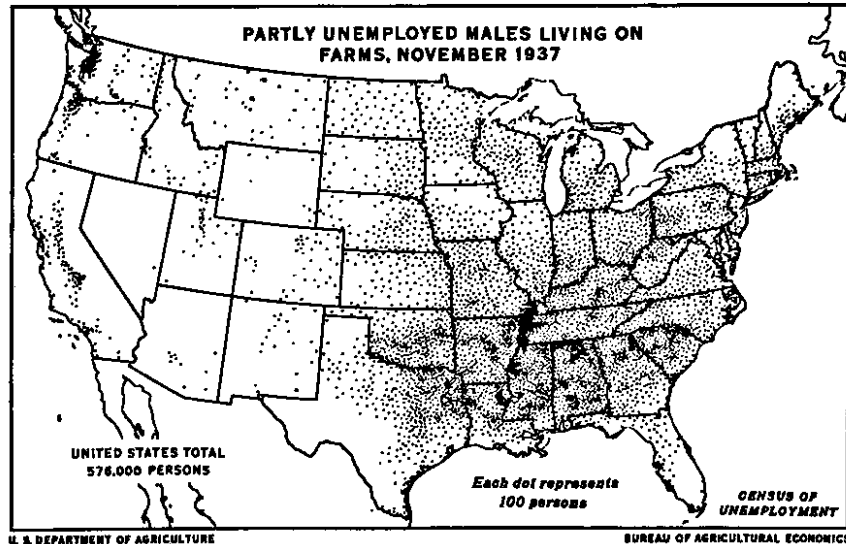

It does not, therefore, appear that the unemployment situation among farm families will correct itself through natural migration away from farms unless we have an industrial pick-up far beyond anything that has happened up to the present. Should the rate of net migration away from farms during the next two decades be half as great as during the decade from 1920 to 1930, the increase in the farm population of productive age from 1940 to 1960 would be 23 percent, and the problem of unemployment on farms would become one of the major problems of the Nation. Unless therefore net migration to the cities from farms develops in great volume, or new opportunities for employment are developed in agriculture, the problem of unemployment in the farm population will grow steadily worse.

The next chart simply shows the partially employed.

(The chart referred to was marked "Exhibit No. 2643" and appears below.)

EXHIBIT No. 2643

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

Persons living on farms who registered in the unemployment census of November 1937 as partly unemployed were numerous in the Cotton Belt, particularly in the Mississippi River bottom lands of eastern Arkansas and southeastern Missouri. But large numbers registered also in the Appalachian region, extending from Maine to northern Georgia and Alabama, in Ohio, Indiana, Missouri, and the Lakes States, also in the valleys of the Pacific Coast. Relatively few registered in the Corn Belt and the Wheat Belt.

Dr. TAYLOR. The only thing I do not comment upon in the written statement you have there is anything concerning the location of these unemployed and partially employed people. I might make one generalization concerning that, and that is that the greatest number of unemployed, partially employed, and employed in emergency works programs of different kinds appear in those very areas of the Nation where the birth rate is highest and where the farm population is stacking up in competition with itself in a most marked way.

Acting Chairman WILLIAMS. In that connection what is considered "partly unemployed" on a farm? What is the definition? What class do you cover with that term?

Dr. TAYLOR. These data are from the unemployment census and I'm sorry I don't know what they used for that. In the regular census \$150 income off the farm would make you partially employed in industry, but I am sorry I can't say what the unemployment census figures used. I don't know whether any of the other men know that definition for their unemployment or not.

Mr. Holcomb, Mr. Chairman, will take this story of the farm population and farm labor on through the next charts.

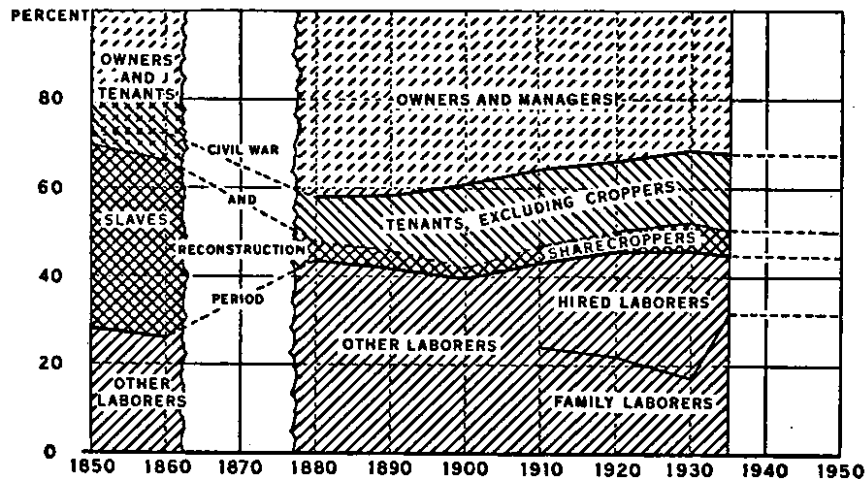

Mr. HOLCOMB. Dr. Taylor has already shown in the first chart that there has been a steadily diminishing percentage of the gainfully employed in agriculture. I am submitting a chart showing the percentage in each tenure class gainfully employed in agriculture.

(The chart referred to was marked "Exhibit No. 2644" and appears below.)

EXHIBIT No. 2644

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

PERCENTAGE IN EACH TENURE CLASS GAINFULLY EMPLOYED IN AGRICULTURE, UNITED STATES, 1850-1935, WITH ESTIMATED CONTINUATION OF TREND LINES PROJECTED TO 1940 AND 1950

U. S. DEPARTMENT OF AGRICULTURE

BUREAU OF AGRICULTURAL ECONOMICS

INCREASE OF FARM TENANCY

Mr. HOLCOMB. Since 1880 there has been a continuous decrease in the proportion of farm owners and an accompanying increase in the proportion of farm tenants. In 1880 owners were 42 percent of all those engaged in agriculture; in 1935 they were 31.8 percent. Because of debt, the real equity of operating owners was less in 1935 than these figures indicate. In 1880 the tenants formed 14.4 percent of all the persons employed in agriculture; in 1935 they formed 23.1 percent.

A part of the reported growth of tenancy in the United States since 1880 has consisted of movement from the status of laborer to that of cropper, which in many cases means little or no advance up the agricultural ladder, since the status of southern croppers is more like that of laborers than of tenants elsewhere. Between 1920, when it

first became possible to classify croppers separately from other tenants, and 1935 the proportion of tenants other than croppers increased from 16 to 17.3 percent, and the proportion of croppers from 4.7 to 5.8 percent of all persons employed in agriculture. In 1920 croppers constituted 22.9 percent of all tenants, and in 1930, 29.1 percent. Between 1930 and 1935 their numbers declined from 776,000 to 716,000, or to 25 percent of all tenants. As further technological improvements are made, their numbers are likely to decline still further.

The figures upon which this chart is based indicate a downward trend from 1880 to 1900 in the proportion of laborers and thereafter a trend upward. The imperfections in the census data for those years are such that, on slightly different assumptions as to the corrections to be made in the census figures, an increase in the proportion of farm laborers up to 1910 could be shown, and thereafter a definite slowing up of the rate of increase in the proportion of farm laborers. The main point to be observed is that during the past 30 years there has been no decrease in the proportion of laborers, but rather a tendency toward increase of that of hired hands. This development is as significant as the increase in the proportion of tenants. It is likely to continue. In many areas it has been offset to some extent by increasing use of power machinery.

I would like to point out, in connection with "Exhibit No. 2644," the line sloping upward between the family laborers and hired laborers between 1930 and 1935. We do not attach any particular significance to the magnitude of that change, but the direction of the change I think is significant.

Acting Chairman WILLIAMS. Have you got a reason for that?

Mr. HOLCOMB. Dr. Taylor has already pointed out one thing—the movement of population during that period. There was a net migration back to the farms, and during that period I believe the following witness will show that there has been a more rapid increase in mechanization. It is probably a joint phenomenon of increasing farm population and mechanization.

Dr. TAYLOR. May I add a remark, Mr. Chairman?

Acting Chairman WILLIAMS. Yes.

Dr. TAYLOR. I think it is partly due also, as Mr. Holcomb said, that when you get in a tough spot on a farm you simply quit paying the son, therefore he is no longer hired labor but a family worker; you quit hiring a hired man and you and the children do the work, so in a period like that you naturally have fewer hired men and more family labor. I would like to tie this chart up also a little bit to the testimony I gave by saying that I think it gives a part of the result of the heavy competition of farmers with each other when your population piles up, and they do compete heavily with each other. You find a greater and greater number of them shifting to the bottom rungs of the agricultural ladder, as is shown with the number of decreasing owners, and the increase of tenants and laborers and share croppers. That is happening in our total farm population, an ever greater number of them appearing on the lower rungs of the agricultural ladder.

Dr. ANDERSON. Dr. Taylor, if you substitute actual numbers for the percentages shown in this chart, would the number of owners be decreasing?

Dr. TAYLOR. Yes; over the period the number of owners would decrease. When you get down into the tenant group, during the last

few years the numbers would increase but the percentage would not increase, so your numbers would be different from your percentage figures.

Dr. ANDERSON. Is that true with respect to laborers as well? The number of laborers has grown.

Dr. TAYLOR. By and large I think the number has remained pretty steady in the labor group itself. After you drop below the owner group, you have a different meaning for labor there than you may have in hired labor. You have in the upper part of the chart owner operators, and below that "all others"; and you have the total farm population in considering your percentages, rather than just those operating farms.

Acting Chairman WILLIAMS. In order that we may have in the record a clear understanding of tenant and share cropper, what is the distinction upon which that chart is based?

Mr. HOLCOMB. The distinction is largely the one used in the census. The matter of ownership of work stock and equipment was the basis in the several censuses. The share cropper does not own his work stock and equipment, the renter does.

Acting Chairman WILLIAMS. And then what is the difference between the laborer—or is there such a term? You don't seem to designate it, as a farm laborer and sharecropper.

Mr. HOLCOMB. The wage laborer is the second group from the bottom. He works for a wage, monthly, weekly, or piece rate, while the sharecropper works for a share of the crop.

Acting Chairman WILLIAMS. Is that hired labor in cash or part crop? Always in cash?

EARNINGS OF FARM LABORERS

Mr. HOLCOMB. Yes. Of course, in many areas there is a custom of allowing them a dwelling place and garden patches and grazing privileges for their livestock, I should say, in addition to their money wage.

Acting Chairman WILLIAMS. That was my understanding of those terms, but I thought it might be well to make it plain.

Mr. HOLCOMB. In the next two tables we present some information as to the earnings of sharecroppers and wage laborers.

(The tables referred to were marked "Exhibits Nos. 2645 and 2646" and are included in the appendix on pp. 17440-17441.)

Mr. HOLCOMB. The first one compares the income of sharecroppers and wage laborers. The data of incomes of hired farm workers are so scattered and incomplete as to defy comparison. However, it is apparent that such incomes are low, and that they are lower in some farm areas than in others. Comparable data from cotton farms indicate that in recent years the net cash earnings of hired workers, whether sharecroppers or wage hands, only occasionally exceed \$100 per worker per year, and that even when goods for home use and perquisites are added, total annual net income per worker seldom exceeds \$150. Low net cash incomes of sharecroppers were reported in recent studies from both the eastern Piedmont and the Mississippi Black Belt and Delta areas. The highest net cash earnings were in the Piney Woods area of Texas in 1938, with an average of \$152 per worker. In the case of cotton wage hands, the lowest average

cash earnings reported were \$65 per worker per year in the Black Belt in 1934, while the highest earnings were in 1937 in the Delta areas at \$112 per worker.

The data indicate that as regards income the cropper is little better off than the wage hand. The slight income differential in favor of the former is almost wholly accounted for by the differences in the value of production for home use. Per family the difference is greater because of the larger average size of the cropper family.

I would like to point out, in addition, in connection with this, the percentage of their total net income that accrues from home-use goods and perquisites, as is shown in the third column. That ranges from about 30 percent in 1936 for the Yazoo-Mississippi Delta area to approximately 52 or 53 percent in that same area in 1932; the dollar values attached to those home-use goods and perquisites were not greatly different between the 2 years, but the percentage of the total increased materially.

For the wage hands, the percentage represented by home-use goods and perquisites did not range quite so widely. Their home-use goods and perquisites are quite a bit lower than that of sharecroppers, I think principally because of the relative instability of that group of workers, for at least the sharecropper has 1 year that he can count on being on the farm.

Passing on then to the next table, we show income figures for wage hands in various areas in the United States, from studies that have been made from time to time.

(The table referred to was marked "Exhibit No. 2647" and is included in the appendix on p. 17442.)

Mr. HOLCOMB. These are for the period between 1930 and 1938. With respect to other areas and crops than cotton, few comparable studies have been made, owing to variations with respect to home-use products, perquisites, total family earnings, and total earnings throughout the year. However, taking the figures as they stand, incomes of farm laborers in the various areas, the studies may be grouped as follows:

Arranging them from lowest to highest, from these spot studies, the lowest income appears to be in the tobacco area of Kentucky, between 1935 and 1936, with cash earnings of \$188. In the small-grains area of Minnesota and Kansas those earnings amounted to \$206 and \$205, respectively. In the truck area of New Jersey, in 1936, the earnings amounted to \$265, and in the Corn Belt in Illinois and Iowa in 1935-36 the cash earnings of wage hands amounted to \$306 and \$312, respectively.

A study made in four sugar-beet States in 1935 indicated that their earnings amounted to about \$340.

In the State of Washington, laborers working in hops earned \$352; that is, single persons. Heads of families earned \$496.

In California we have two studies during this period. The first was made in 1935 and indicated that the earnings of migrant workers who had applied for relief at the close of that year were \$261; and in another study in Placer County, a fruit county in California, the earnings amounted to \$651. That study took the workers as they came in the fields, irrespective of whether or not they were on relief.

Acting Chairman WILLIAMS. Does that mean that there has been that much increase in the earnings of the hired laborers in California during the period?

Mr. HOLCOMB. As a matter of fact, you will notice in section IV of "Exhibit No. 2647," between 1930 and 1935, there was an actual decrease in the earnings of these workers. These are migrant workers who applied for relief at the close of the particular year.

Acting Chairman WILLIAMS. What is the significance of the big difference between those two figures in the same State, of \$261 and \$651?

Mr. HOLCOMB. The figures shown under section IV (A) on the chart are obtained from the entire State from relief applicants who had worked as migrant workers in agriculture during the past year. Under IV (B), the study made by the Department of Agriculture was made in one county in California, and they obtained information from workers irrespective of whether or not they obtained relief.

Mr. PIKE. You got the lowest section, though.

Acting Chairman WILLIAMS. I don't quite understand yet what you mean by "relief." Does that mean the workers who were on public relief?

Mr. HOLCOMB. That is a study made by the State Relief Administration of California, and they obtained this information from clients as they applied for relief.

Acting Chairman WILLIAMS. Take the figure of \$261 in California in 1936. What does that represent?

Mr. HOLCOMB. That probably represents the lowest-down group employed in agriculture.

Acting Chairman WILLIAMS. But if they are employed, they are privately employed?

Mr. HOLCOMB. Yes.

Dr. ANDERSON. Mr. Chairman, I can explain the figure, because I know something about its source. Applicants for relief at the State relief station stated that during that year their earnings per family had totaled this amount.

Mr. PIKE. They were irregularly employed.

Dr. ANDERSON. They were casuals, migrants, and seasonal harvesters employed during that year at some sort of agricultural labor.

Mr. PIKE. That wouldn't be a fair section of the agricultural laborers in the State.

Dr. ANDERSON. That is precisely what Mr. Holcomb said. It is the lowest rung of the agricultural group.

Acting Chairman WILLIAMS. Is the 651 intended to be a fair average?

Mr. HOLCOMB. I think it is a fairly representative figure for that one county.

Acting Chairman WILLIAMS. Oh, just for the one county. That is what kind of industry, the fruit industry?

Mr. HOLCOMB. Fruit. It is in the section north and east of Sacramento.

Acting Chairman WILLIAMS. What, in addition to cash income, do these hired laborers receive? What other kind of income do they have, if any?

Mr. HOLCOMB. Most of them receive some perquisites. It varies from area to area. Some studies have been made along that line. In

the South and East it amounts to quite a bit. What it amounts to in the western areas I don't know.

Acting Chairman WILLIAMS. What is the nature of it?

Mr. HOLCOMB. Fruits, perhaps culls, lodging, occasionally board, and in some instances washing and ironing for the men.

Acting Chairman WILLIAMS. A garden patch for married men?

Mr. HOLCOMB. For those regular workers, yes; but not the seasonal workers.

Acting Chairman WILLIAMS. And a house or hut to live in?

Mr. HOLCOMB. That is right; a place to live.

Dr. ANDERSON. You wouldn't imply that the workers receiving \$651 in Placer County were year-round workers in that county who were provided these perquisites.

Mr. HOLCOMB. No; many of them were, as a matter of fact, migrant workers, and I don't know what the amount of perquisites amounted to in that particular study. I don't know that they obtained information with respect to perquisites. That figure probably should be taken into account, or it should be taken into account in that figure that the expense of moving about was not obtained in the study. How much that moving around from place to place was, I don't know.

Dr. TAYLOR. That includes the very best and the very lowest. It averages up pretty high, because it includes those permanently employed and those who have a house, and so forth.

Colonel CHANTLAND. Isn't it a fact that in certain sections the common practice is, in the employment of labor, that they are founded completely—they have their board and washing and ironing, so that what they get is net in that sense? These migrants are not in that class, are they?

Mr. HOLCOMB. No. Occasionally they do receive fruits, though.

Colonel CHANTLAND. I heard you say that.

Acting Chairman WILLIAMS. Have you made a study to indicate what influence this especially large migration in California has had on wage rates there when they hire farm labor?

Mr. HOLCOMB. A study was made a year or so ago. The tabulations are now going on in our regional office in Berkeley, Calif. Just what that will show I am not certain yet. The tabulations are not complete.

Acting Chairman WILLIAMS. I was just wondering whether John Steinbeck's portrayal was anything like accurate in his *Grapes of Wrath*.

Dr. ANDERSON. I might interrupt to say that Dr. Paul Taylor, who will be on the witness stand tomorrow afternoon, is the authority on this western problem. We brought him particularly because of the interest in it, and he is prepared to give such data as are available on that subject.

Acting Chairman WILLIAMS. Proceed.

Mr. HOLCOMB. These data are not shown on that chart. There were studies made in 11 different areas in the year 1936 by Folsom and Vasey of the Department of Agriculture which show cash earnings of workers in 11 different areas. The cash earnings range all the way from \$126 in the self-sufficing area of Tennessee to this same \$651 figure in Placer County, Calif. The lower incomes were in the southern areas, and the higher incomes were in California, the dairy areas, and in the Corn Belt.

Acting Chairman WILLIAMS. Is there any indication—let me ask you in connection with the various figures that you have given here—as to the time in which these laborers were employed during the year; for instance, whether their period of employment was much longer in one area of the country than it was in another, and for that reason perhaps their wages might be higher or lower, depending upon the period of regular employment? I am talking now about the ones who are regularly employed and considered so.

Mr. HOLCOMB. There is some data available on the seasonal distribution of employment, and we parleyed once about presenting that information, but we decided against it because of the length of testimony and the shortness of the time we were permitted to use. That information could be made available. I don't have it with me now.

Concerning the seasonal distribution of workers in the Southern States, they have two peak periods, particularly in cotton, around the cotton chopping and hoeing times, and again in the cotton-harvest times. That varies from one part of the Cotton Belt to the other. In the Southern States the first peak in cotton chopping and hoeing is far more significant than it is in the western end of the belt, in western Oklahoma and Texas. That particular peak is negligible in the Cotton Belt, but in the cotton harvest it is quite significant in all areas.

Acting Chairman WILLIAMS. The annual income might not be an index as to the hourly wage he received.

Mr. HOLCOMB. That is right.

Acting Chairman WILLIAMS. By reason of varying periods of employment in the same year in one place and another.

Mr. HOLCOMB. We have two studies, the manuscripts for which have been completed. One is for two counties in South Carolina, one in the Piedmont cotton area, and one in the Coast Plains tobacco section. Also, there is another study in Arkansas. A mimeographed bulletin has been released to three counties, and the manuscript is now in hand to be published in the near future for six additional studies, three of which are in the delta and three in the hills.

In those studies the seasonal distribution of employment and the earnings by month are shown. There is quite a significant change in earnings from January to May, the first peak, and it dropped along about in August, which is comparable, perhaps, with March or February, the peak rising again and continuing until early November, when it drops off to a low during the winter months. With that distribution of earnings and the hours of work, from the number of days worked, it is possible to show the daily earnings in terms of real wage rates received by sharecroppers and wage laborers, and as I recall in the South Carolina study, it runs around 70 cents a day.

Acting Chairman WILLIAMS. Of course, I believe you stated that it was a fact that the annual income, perhaps as the daily income, of the farm laborer in the South was lower than it was in Northern and Western States. That is pretty generally recognized, isn't it?

Mr. HOLCOMB. I think it is fairly true. There haven't been many studies made that can be used to compare it to make it a statement of fact, but there is reason to believe that.

"GAINFULLY EMPLOYED" IN AGRICULTURE

Mr. HOLCOMB. The next table shows the number of gainfully employed persons in agriculture. The table shows the total employment between 1909 and 1939. The index of the trend line, based upon the 1924-29 average, shows the number of family workers, which includes the operators of the farms themselves, and their dependents who worked with them without pay, and the number of hired workers.

(The table referred to was marked "Exhibit No. 2648" and is included in the appendix on p. 17443.)

Acting Chairman WILLIAMS. I don't believe we have had a definition in connection with this study here as to what you mean by gainfully employed.

Mr. HOLCOMB. I think, according to the Census definition used by the Agricultural Marketing Service in developing this series of data, it is those persons 10 years of age and over gainfully employed in agriculture.

Acting Chairman WILLIAMS. Just the expression "gainfully employed" itself is what I am inquiring about.

Mr. HOLCOMB. In this it is the number of persons who worked 2 weeks or more during the month of January, so it is conditioned by census enumeration data. However, these data were adjusted to indicate an average for the year, to eliminate the bias of a particular date of enumeration.

Acting Chairman WILLIAMS. I must confess that that isn't very clear to me yet. It may be to all the others, and I don't want to labor the question any further. It isn't entirely clear in my mind what is meant by the expression "gainfully employed."

Dr. TAYLOR. It simply means that the person does work. He may be past 10 years of age, but if he does no work in any occupation, he is not classed as gainfully employed.

Acting Chairman WILLIAMS. Regardless of the amount he does. If he worked 1 day during the year, he would be gainfully employed.

Dr. TAYLOR. If he earned money; yes. You asked a moment ago about the partially employed in the unemployment. I don't know what definition they used there, but if a fellow works and earns \$5, he would be partially employed.

Acting Chairman WILLIAMS. Let me see that I understand it. As I understand you now, it would mean anybody that was employed for any length of time during the year would be considered gainfully employed.

Dr. TAYLOR. That is right.

Acting Chairman WILLIAMS. If he did anything for which he received money during the year.

Dr. TAYLOR. That is right. And the figure that Mr. Holcomb gave of those who were employed for a given period of time preceding the taking of the census applied only to farm labor, as to whether he would be counted a farm laborer or not, provided he had been employed then, but there is a difference of meaning in the descriptions as to whether you are a farm laborer of working age, or gainfully employed. They are all different things.

Acting Chairman WILLIAMS. You might say all those who are available for employment within certain ages during that year, because if

he is only employed for an hour or a day, it would cover the entire field.

Dr. TAYLOR. It can't be quite all those who are available, because there would be some in there who didn't work.

Mr. HOLCOMB. As a matter of fact, I believe the census in 1930 showed about 8 percent of the females 10 years of age and over who lived in rural farm areas were employed in agriculture, and about 69 percent or 70 percent, something like that, of males working, came from employment in agriculture, but these figures are the average number of persons employed on the first of each month.

Acting Chairman WILLIAMS. It doesn't, then, include the family workers, the boys, and I will say the girls, who were working at home for their parents.

Mr. HOLCOMB. Yes; they are included in that middle column, family workers.

Acting Chairman WILLIAMS. They are included as gainfully employed, are they?

Mr. HOLCOMB. Yes; they are helping produce on farms—the number of family workers employed on farms, including the farm operator himself, on the first day of each month.

Acting Chairman WILLIAMS. Then it really includes everybody who does any work on the farm?

Mr. HOLCOMB. That is right—10 years of age and over.

Acting Chairman WILLIAMS. We are getting about down to it now, I think.

Mr. HOLCOMB. It appears that from 1909 to 1915 there was a slight decrease in agricultural employment which, after a slight increase in 1916, fell rapidly until 1919, owing to the competition of other industries with agriculture for manpower. From 1919 there was a slight increase until 1926, when a downward trend set in which continued without interruption in 1935 until 1939.

Wage laborers in agriculture numbered 2,868,000 in 1909, while in 1939 this number had been reduced to 2,479,000. However, between 1909 and 1929 the trend was slightly upward. Thereafter, until 1934, there was a decrease in hired laborers and an increase in the number of family workers. Although from 1935 to 1937 there was an increase in the number of hired laborers, in 1938 the trend was again downward.

Dr. ANDERSON. Mr. Holcomb, what was the proportion of hired laborers to family workers, including the farmer himself, in 1939—2,479,000 to 8,150,000?

Mr. HOLCOMB. The proportion of hired laborers represented by family workers?

Dr. ANDERSON. The proportion hired laborers are of the total, which would give the percentage rate.

Mr. HOLCOMB. I am not sure that I follow you.

Dr. ANDERSON. Let me put it this way. It would appear from this that about 30 percent of farm employment is hired-labor employment.

Dr. TAYLOR. Only about 25 percent.

Mr. HOLCOMB. About 25 percent of all persons employed in 1939 were hired labor. I think there is quite a variation in those proportions with changes in prices and changes in wage rates. You take both of them into consideration.

Dr. TAYLOR. It varies greatly in certain sections of the country, too.

Dr. ANDERSON. Well, I would like to have comment on this other point. In the census of gainful workers—and this will explain partly the chairman's question of a moment ago—which includes both employed and unemployed, but available for employment, the total in 1930 was 4,392,000 agricultural laborers. In your segregation of hired workers actually employed at a given time in the month average employment for the year 1930 was 2,850,000.

Mr. HOLCOMB. Yes; the census, I believe, obtained their information as to the number of hired workers as of the date of enumeration.

Dr. ANDERSON. That is right.

Mr. HOLCOMB. These are monthly averages as obtained from the crop reporters from the farmers.

Dr. ANDERSON. Would the difference, roughly, approximate the number of agricultural laborers available but unemployed? In other words, there is apparently a plentiful supply of agricultural labor.

Mr. HOLCOMBE. Yes; I am sure there must be.

Dr. ANDERSON. Would this indicate an oversupply of agricultural labor in terms of employment, available employment opportunities?

Mr. HOLCOMBE. I suspect that it would. I haven't that accurately.

Dr. ANDERSON. Mr. Chairman, that concludes the testimony, and we can go on to the next witness.

Acting Chairman WILLIAMS. Thank you, gentlemen.

(The witnesses, Dr. Taylor and Mr. Holcombe, were excused.)

Dr. ANDERSON. The next two witnesses are Dr. Sherman Johnson, Division of Farm Management and costs; and Dr. Louis Bean, the economist of the Bureau of Agricultural Economics; and I would like of have Dr. Kifer, of the Division of Farm Management and Costs, at the same time.

Acting Chairman WILLIAMS. Have you been sworn?

Dr. BEAN. I have, sir.

Acting Chairman WILLIAMS. Do you and each of you solemnly swear that the testimony you are about to give in this proceeding shall be the truth, the whole truth, and nothing but the truth, so help you God?

Dr. JOHNSON. I do.

Dr. KIFER. I do.

TESTIMONY OF SHERMAN E. JOHNSON, HEAD OF DIVISION OF FARM MANAGEMENT AND COSTS, UNITED STATES DEPARTMENT OF AGRICULTURE, WASHINGTON, D. C., AND LOUIS H. BEAN, ECONOMIST, BUREAU OF AGRICULTURAL ECONOMICS, UNITED STATES DEPARTMENT OF AGRICULTURE, WASHINGTON, D. C., AND DR. R. S. KIFER, DIVISION OF FARM MANAGEMENT AND COSTS, UNITED STATES DEPARTMENT OF AGRICULTURE, WASHINGTON, D. C.

Dr. ANDERSON. Mr. Chairman, we just asked for a definition of partially employed workers according to the 1937 census, and learned that the Census Bureau made no precise definition at the time for use by enumerators. The enumerators left cards with farmers, and they

were filled out on each farm according to approximation of partial employment on the farm.

Acting Chairman WILLIAMS. Have you a statement to make first?

Dr. ANDERSON. The witness may proceed.

Dr. JOHNSON. My testimony will be concerned primarily with four points: First of all, the reduction in the amount of labor used for producing different crops, largely accounted for by increases in mechanization; then some tendencies of increases in mechanization on the farm, shown by increase in tractors, and so on; thirdly, the effect of mechanization on physical efficiency in the use of labor on farms; and, lastly, the effect of mechanization on the investment in the farm business, and on operating expenses.

The first two charts show labor used in producing wheat and oats.

(The charts referred to were marked "Exhibits Nos. 2649 and 2650" and appear on pp. 16942-16943.)

PRODUCTIVITY IN AGRICULTURE

Dr. JOHNSON. They show the changes in the amount of labor used in producing wheat and oats. The first chart refers to the amount of labor used in producing wheat by different areas and in different periods from 1909 to 1936. The different perpendicular bars show the amount of labor used for these different periods, reading from left to right. The bar labeled A refers to the period 1909-13, the B bar, 1917-21; the C bar, 1927-31; and the D bar, 1934-36. That information is shown for different regions in the country, which are labeled. The first set of bars indicates the changes in the amount of labor used in wheat production for the United States as a whole. Then we come to the Corn Belt region, next the eastern dairy, which is largely the northeastern part of the country, and next the western dairy region, the Lake States.

Acting Chairman WILLIAMS. Before you go any further, I think I would like you to tie up those with the years.

Dr. JOHNSON. The first one is 1909-13, the second is 1917-21, the third is 1927-31, and the fourth is 1934-36; roughly, we can say pre-war, the World War period, the late twenties, and the post-war.

On the amount of labor used per acre in wheat production, taking it first for the United States as a whole, you will notice that only about half as much labor was used per acre in 1934-36 as was used in the first period, 1909-13. This is largely accounted for by the use of tractors, tractor equipment, combines, of course, along with tillage equipment for use with the tractor. There is also the question of shifting of wheat production to the plains areas, to the more level areas, where machines can be used to better advantage. The least amount of labor per acre is used in the small grain area which, as indicated in the exhibit here, includes the Dakotas, Montana, Nebraska, and Kansas; and also the region called the western cotton area, which is the wheat-producing area of Texas and Oklahoma.

Only about 3 or 4 hours of labor per acre were used in the small-grain areas and in the western cotton area, and those areas or regions actually used less labor in 1909-13 than some of the Eastern and southern areas did in 1934-36.

Mr. PIKE. Those are the highly important areas in grain growing?

Dr. JOHNSON. Those are the most important areas in grain pro-

EXHIBIT No. 2049

EXHIBIT No. 2650
[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

duction. One should include also the northwestern area, Washington, Oregon, and Idaho.

Dr. ANDERSON. Why do you use the measure of hours per acre?

Dr. JOHNSON. Hours per acre? Well, of course, one could use hours per hundred bushels, or hours producing a bushel of wheat.

Mr. PIKE. You have done that on potatoes?

Dr. JOHNSON. We have done that on potatoes, that is right, and also in the wheat tier; for the western cotton area and for the small grain area it runs from 0.3 to 0.4 hours per bushel. The average yield out there is about 10 bushels per acre. I might say that that is the customary method.

Dr. ANDERSON. That is the commonly accepted method?

Dr. JOHNSON. That is the commonly accepted way of portraying the amount of labor used in production.

Turning to the next set of charts, I want to discuss corn first.

(The chart referred to was marked "Exhibit No. 2651" and appears on p. 16945.)

Dr. JOHNSON. The labor used per acre for corn production does not show as marked a proportional decrease as does the labor used per acre in wheat production. The most outstanding evidence that we have of the effect of mechanization is on wheat production. However, as far as labor used per acre, the reduction in actual hours per acre is concerned, it amounts to about the same reduction in corn production for the country as a whole as it does for wheat production, namely, about 6 hours per acre; a change for the country as a whole from 29 hours in the 1909 period to 23 hours in the 1936 period.

A part of this decrease in corn production is due to the use of corn pickers in the Corn Belt, but probably more resulted from the use of tractors and multi-equipment. I think that is much more important.

I want to call attention also to the fact that a relatively small amount of labor is used in corn production in the winter wheat and spring wheat areas. They have less cultivation, less tillage, and very often, of course, the yields are much less.

The next chart is Labor Used Per Acre Producing Cotton in Major Areas.

(The chart referred to was marked "Exhibit No. 2652" and appears on p. 16946.)

Mr. PIKE. The chart is not complete?

Dr. JOHNSON. That is right. They were borrowed from another source. Reading from left to right, the first set of 4 bars is for the United States as a whole; the second one is for the eastern cotton area; the third set is the Delta area, Arkansas, Mississippi, Louisiana; and the last set is for the western area, Texas and Oklahoma, the latter representing the newer cotton areas where mechanization up to picking time has become very important. As a matter of fact, it is the only area where there is outstanding evidence of a reduction of labor in cotton production. Most cotton is still picked by hand.

The decrease shown, then, for the country as a whole is largely due to the shifting of cotton production during that period to the western cotton area.

I might say that the development of an acceptable cotton picker would, of course, make a revolution in cotton production comparable to that which has already taken place in wheat production, perhaps.

EXHIBIT No. 2651

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]
Variations by Areas in Labor Used Per Acre in Producing Corn, 1909-36

WPA - National Research Project
A-29

The next chart shows the amount of labor used in potato production by selected counties rather than for areas as a whole, and those counties are, first, Clay County, Minn.; second, Waupaca County, Wis.; third, Montcalm County, Mich.; fourth, Steuben County, N. Y.; fifth, Suffolk County, N. Y.; and, last, Aroostook County, Maine.

(The chart referred to was marked "Exhibit No. 2653" and appears on p. 16947.)

Dr. JOHNSON. In Aroostook County, Maine, there has been a net reduction of 14 hours per acre, and in that county the yields were increased nearly 90 bushels per acre between 1909 to 1936, so that the time used to produce and market 100 bushels of potatoes—and here we put it in the other terms—in 1936 was only 16 percent of that required in 1909.

EXHIBIT No. 2652

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

In Clay County the yields per acre were down during the period; consequently the man-hours per hundred bushels actually went up.

I am going to read a short statement here on mechanization in other lines.

Some of the most striking examples of labor saving equipment are those used on relatively minor crops. Although these types of equipment—the cane stripper, the pick-up baler, the field ensilage cutter, the mechanical beet blocker, etc.—have not been used on large acreages, they do have an actual or a potential influence on labor requirements in particular sections of the United States. A good example is the combination of mechanical pea harvester and huller in use with newly developed processes of quick-freezing and packaging in the preparations of peas for market.

(The chart referred to was marked "Exhibit No. 2654" and appears on p. 16948.)

Dr. JOHNSTON. I turn now to the second part of the testimony, some evidences of mechanization. The next chart is on tractors.

(The chart referred to was marked "Exhibit No. 2655" and appears on p. 16948.)

Dr. JOHNSON. This shows the number of tractors of all types on farms January 1, 1915, to January 1, 1939. Starting from an almost insignificant number in 1915 we see a spurt during the World War period which extended up to 1921, a slowing down during the depression of the early 1920's, and then again a spurt in the latter 20's, a slowing down again in the early 30's, and again a later spurt after 1935.

Labor Used in Potato Production in Selected Areas 1909-38

WPA - National Research Project
A-10

In 1930 there were 900,000 tractors on farms. These were mostly either the standard type or the crawler tractors. Some standard tractors were used in the Corn Belt, particularly on the large farms, but with the development of the general purpose tractor, and particularly with the addition of pneumatic tires to tractors, the use of tractors and mechanical equipment increased rapidly in the Corn Belt and in the Eastern States, so that we have estimated for 1939 1,600,000 tractors. With further improvement in tractor design and especially with the recent introductions of the small tractors, we can expect mechanization to take place in some of the eastern areas and the Southeastern States where tractor use has not made the advances that it has in the Midwest and the small grain regions.

TRACTORS (ALL TYPES); NUMBER ON FARMS, JAN. 1, 1915 - JAN. 1, 1939

U. S. DEPARTMENT OF AGRICULTURE

BUREAU OF AGRICULTURAL ECONOMICS

Acting Chairman WILLIAMS. Has there been a tendency toward the use of smaller tractors in recent years than larger ones?

Dr. JOHNSON. Oh, yes; there has been a very decided shift to the smaller, general-purpose tractor with pneumatic tires.

Acting Chairman WILLIAMS. That is perhaps due partly at least to using them on smaller farms than they did formerly.

Dr. JOHNSON. Right, and, of course, the general-purpose tractor is more adapted; it is adapted for a good many different operations, and with the power take-off the usefulness of the tractor has been vastly modified.

Mr. PIKE. That has been a development of the last few years.

Dr. JOHNSON. That has been a development in, you might say, the 30's, although, of course, the general-purpose tractor came in the middle 1920's.

Mr. PIKE. There has been a great change, though, in the last decade.

Dr. JOHNSON. Oh, yes, there has been a great change in the last 2 or 3 years, especially in the development of the small tractor suitable for a small family farm.

The other side of the story of tractor increase is shown on the next chart.

(The chart referred to was market "Exhibit No. 2656" and appears below.)

EXHIBIT No. 2656

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

HORSES AND MULES; NUMBER ON FARMS, JAN. 1, 1915 - JAN. 1, 1939

U. S. DEPARTMENT OF AGRICULTURE

BUREAU OF AGRICULTURAL ECONOMICS

Dr. JOHNSON. As the number of tractors has increased on the farms we have had a corresponding decrease of horses and mules. The chart of horses and mules shows the trend in numbers for the same period as was shown for the trend in numbers of tractors. The number of mules has decreased more slowly than horses, largely because mules are used in the South, where mechanization has proceeded more slowly, and also because they are serviceable to a longer age. We find this downward trend in horse numbers is pretty closely

related to lack of replacement of horses, that is young colts, and the horses that are on farms today average much older.

Acting Chairman WILLIAMS. I would think there would be another very important reason in there. It strikes me that the mule is an animal that is used almost exclusively on the farm, while the horse formerly was used as a means of transportation which has been supplanted almost entirely by the automobile.

Dr. JOHNSON. Yes; that is true. The horses were used, of course, for hauling and for going to town.

Acting Chairman WILLIAMS. And for riding horseback.

Dr. JOHNSON. Yes; but, of course, the horse numbers that are shown here are horses on farms.

Acting Chairman WILLIAMS. Well, of course, they would be on the farm. You don't mean the horses and mules that are simply worked on the farm as work animals.

Dr. JOHNSON. Oh, no; I mean kept on farms.

The decrease of about 10,000,000 head of horses and mules during this period releases approximately 50,000,000 acres of land for other purposes; that represents the amount of land that was needed to produce horses' feed, hay, grain, and pasture, horse and mule feed.

Colonel CHANTLAND. Five acres?

Dr. JOHNSON. Approximately five acres per animal, so that that becomes available for cash crops, for pasture and feed crops, for other livestock, for market, and it represents, of course, a part of our surplus crop situation.

The total number of horses and mules is now, roughly, 15,000,000, and it is probable that the number might be stabilized at about 12,500,000 head. However, the recent introduction of the small 1-plow tractor may reduce the horses and mules still further.

The next chart is Percentage of Wheat Acreage Harvested With the Combine.

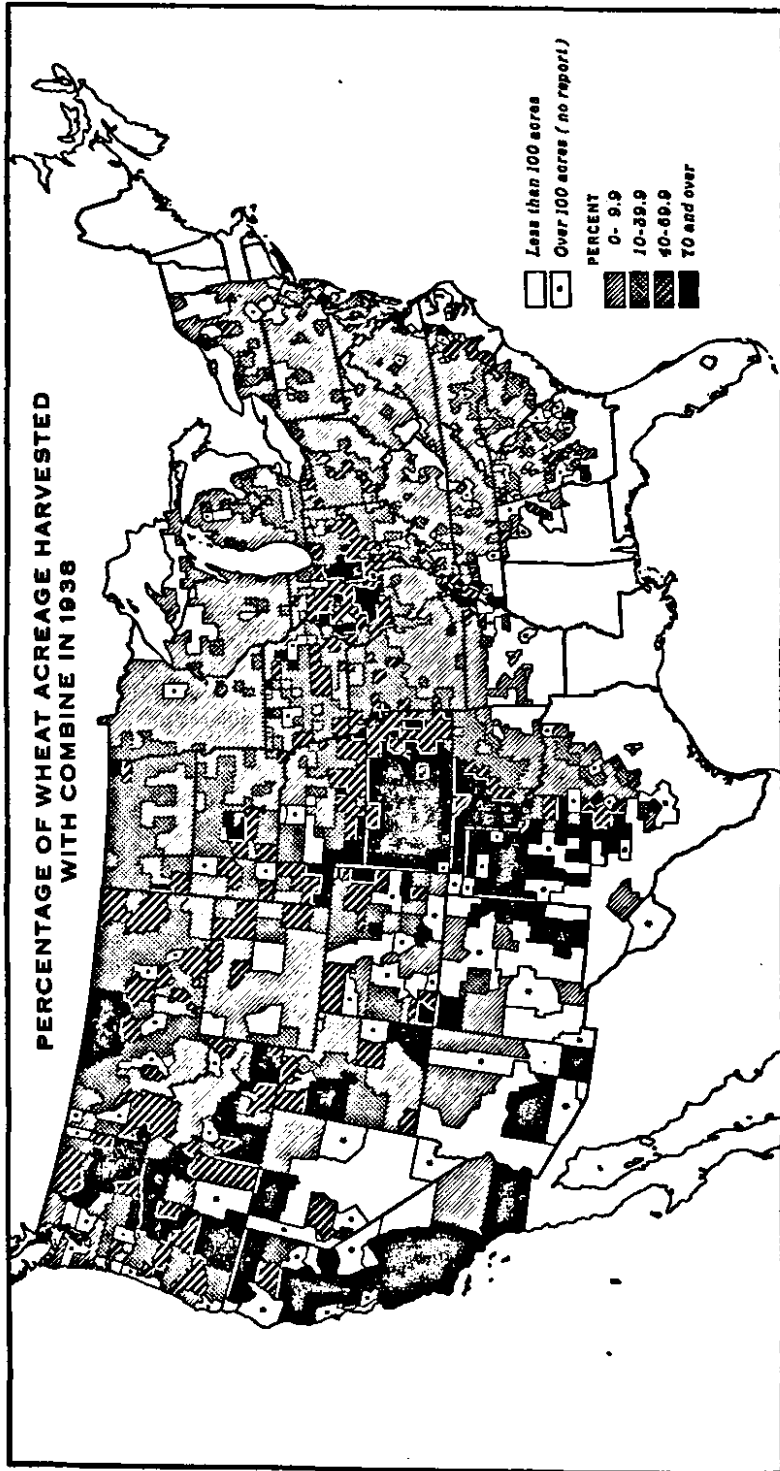

(The chart referred to was marked "Exhibit No. 2657" and appears on p. 16951.)

MECHANIZATION OF FARMING

Dr. JOHNSON. This chart shows the percentage of wheat acreage that was harvested with the combine in 1938. It indicates that the combine is almost universally used in the hard winter-wheat region, in Kansas, Oklahoma, Texas, and southwestern Nebraska. If the crops had been better in previous years, I would expect a much larger number of combines to have gone into the Red River Valley and a part of the important spring-wheat area. Of course, in the Pacific Northwest and in California the combine has been in use for a long time.

The combine is making a very strong bid for the wheat harvest in the soft winter-wheat country of Illinois, Indiana, parts of Iowa, and Minnesota, and Ohio as well. As a result of the use of the combine a crew of 3 men can now perform the same work that was performed by a crew of 8 to 10 men, and can do the work in less time. Probably 110,000 combines are now in use. It has been estimated that somewhere between 100,000 and 200,000 casual migrant laborers found employment in wheat areas in 1920. This opportunity for employ-

EXHIBIT No. 2857

ment has practically disappeared and the extra labor required at harvest is for the most part supplied from local sources.

The next chart is Percentage of Acreage of Corn for Grain Harvested With Mechanical Field Picker, 1938.

(The chart referred to was marked "Exhibit No. 2658" and appears on p. 16953.)

Dr. JOHNSON. I want to call attention to a difference between this chart and the one preceding on combines. The percentages are lower; that is even the areas of greatest concentration here start with 35 percent of the corn harvested with the picker rather than 70 percent in the preceding chart. You will notice, of course, the field pickers have made the greatest inroads in the heart of the Corn Belt, although it is interesting to see that it goes up pretty far into southwestern Minnesota and the eastern Dakotas.

Mr. PIKE. How recent a development is that?

Dr. JOHNSON. The corn picker has been on the market for, I should say, about 15 years, but there have been some very decided improvements in recent years.

Mr. PIKE. They probably have got the cost down to where they have on the combines.

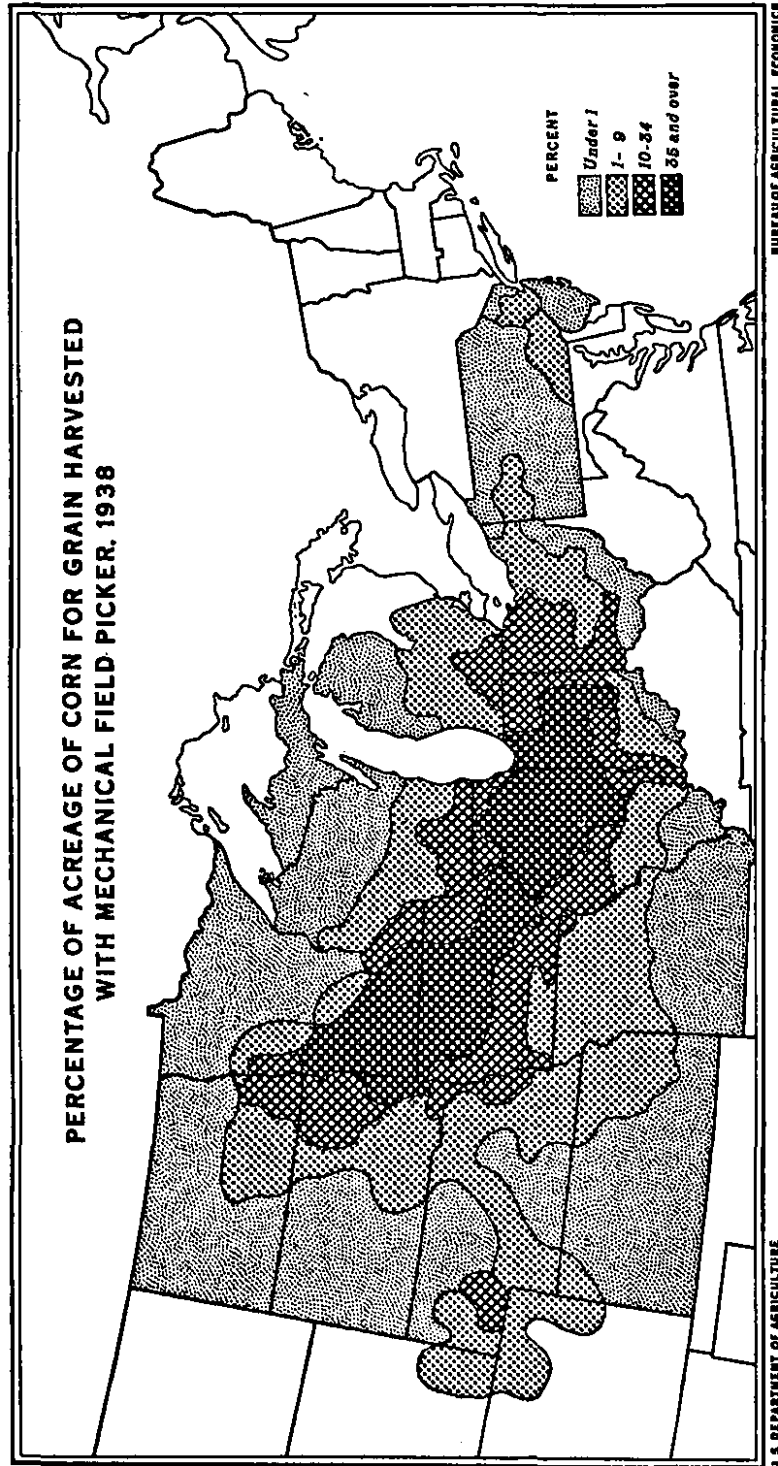

Dr. JOHNSON. They have got the cost down and it is a much more manageable machine. With a 2-row picker and facilities for hauling and cribbing corn yields of 60 to 70 bushels per acre can be harvested with only $1\frac{1}{2}$ to 2 man-hours per acre. Hand picking and scooping would require about 9 man-hours per acre to harvest a 70-bushel yield. Thus it cuts down the labor of harvesting about one-fourth and probably where the picker is used the work will be done largely with family labor.

The next chart is Labor on a 320-Acre Central Kansas Farm.

(The chart referred to was marked "Exhibit No. 2659" and appears on p. 16954.)

Dr. JOHNSON. This chart portrays the changes in the seasonal use of labor, the seasonal distribution of labor, on a half-section central Kansas wheat farm before and after the purchase of tractors. The solid perpendicular bars show the man labor actually used, by weeks, on this farm when it was operated as a horse farm, that is, with horses for power and horse equipment. The cross-hatched bars represent an estimate of the amount of man labor required by weeks when the same farm is operated with tractors and tractor equipment. You will find a broken horizontal line running across the chart which shows the available family labor, available for work on the farm. It represents a man and boy who goes to school part of the year but is available for work in the summertime. You will note, by comparing the solid and the cross-hatched bars, the very important reduction in the amount of labor needed in excess of the family labor, especially during the peak periods which are largely represented there by harvest, first of all, and alfalfa cutters. They have different seasons for the summer months. On this farm when it was operated with horse equipment a hired man was used on the farm for approximately 90 days, or 3 months. With a shift to tractor equipment only about 10 days in extra labor would be required, and this could probably be furnished by exchanging labor with the neighbors. Thus 3 months of hard labor has been eliminated.

EXHIBIT No. 2658

Dr. ANDERSON. Eliminated by the purchase and use of one tractor?

Dr. JOHNSON. By the purchase and use of one tractor and complementary equipment, combine and tillage equipment to go with the tractor.

Dr. ANDERSON. Is this a typical example of what would occur on that size farm generally?

Dr. JOHNSON. It is a typical example of what would occur on that size and type of farm.

Mr. PIKE. That is a mixed farm?

Dr. JOHNSON. No.

Mr. PIKE. It is mostly wheat?

Dr. JOHNSON. Mostly wheat, with some alfalfa and some livestock, but the major income comes from wheat.

Mr. PIKE. And the major work involved, peaks of work, is wheat.

Dr. JOHNSON. Peaks of work represented largely by wheat.

EXHIBIT No. 2659

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

LABOR ON A 320-ACRE CENTRAL KANSAS FARM, BY WEEKS

Mr. PIKE. It is winter wheat. *

Dr. JOHNSON. Winter wheat. You do the seeding in September.

We turn now to the third part of the testimony which indicates the effect of these mechanization changes on physical efficiency in agriculture as a whole.

(The chart referred to was marked "Exhibit No. 2660" and appears on p. 16955.)

INCREASED EFFICIENCY IN AGRICULTURE

Dr. JOHNSON. The solid line represents the employment figures from column 3 of "Exhibit No. 2648," the number employed in agriculture the first of each month, averaged for the year. The line is an index line, with the 1924-29 average considered 100, and the changes are

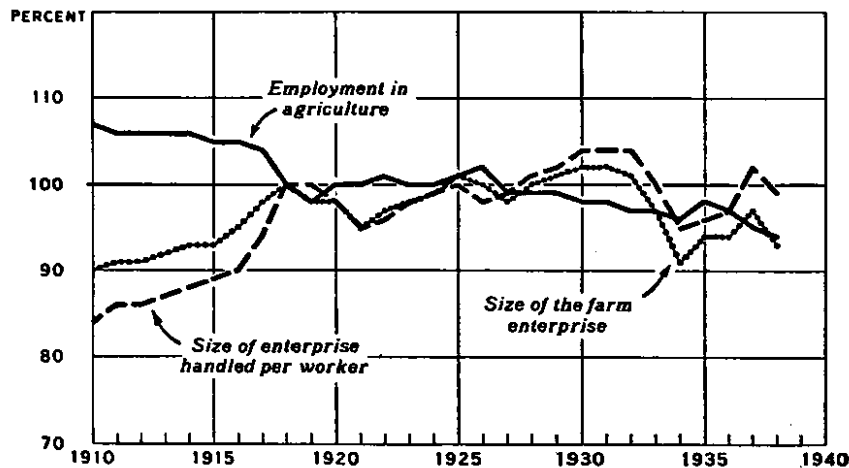

percentage changes from that base. The circled line represents the size of the total farm business in this country in terms of acres of crops and numbers of livestock, weighted on a 1924-29 base, and combined according to the amount of labor that was used during that period. The third line, the broken line, shows the change in size, that is, in acres of crops and numbers of livestock handled per worker, from 1910 to 1938. In the period from 1910 to '16, '17, or up to 1920, we had a rather constant increase in the size of the farm plant, the total size of the farm business. We had a constant decrease in employment in agriculture because of the city-ward movement which has already been portrayed by Dr. Taylor, but, because of the increased efficiency of production, that expansion of agriculture took place with a constant decrease in employment and with a constant increase in the acres of crops and numbers of livestock handled per worker.

EXHIBIT No. 2660

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

RELATION OF EMPLOYMENT IN AGRICULTURE TO THE SIZE OF AGRICULTURAL ENTERPRISE

INDEX NUMBERS (1924-29=100)

U S DEPARTMENT OF AGRICULTURE

BUREAU OF AGRICULTURAL ECONOMICS

Mr. PIKE. The type of expansion we were having is mostly extensive farming of new wheat lands on the western edge of the plains?

Dr. JOHNSON. Yes, at that time; but also a considerable extension in farming; you find increase of dairy farming during that period, which is fairly intensive.

Mr. PIKE. I was thinking about western Kansas and the Panhandle, and so on.

Dr. JOHNSON. Yes; I think that is the most important development. The later part of the period, of course, 1934 to 1938, is very much influenced by the very serious drought years of 1934 and 1936, with not very much of a recovery in 1935. Still this index shows a larger enterprise handled per worker in that last period than in 1910.

Dr. LUBIN. It is rather significant, is it not, that the really great increase in productivity in the agricultural industry occurred between

1910 and 1918, and nothing since then, despite the tractor and all the new equipment, has caused an increase of productivity anywhere near approaching it in an equal length of time?

Dr. JOHNSON. Well, I think that that question will be answered a little bit better by the next chart.

(The chart referred to was marked "Exhibit No. 2661" and appears below.)

EXHIBIT No. 2661

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

RELATION OF EMPLOYMENT IN AGRICULTURE
TO AGRICULTURAL PRODUCTION

INDEX NUMBERS (1924-29=100)

U. S. DEPARTMENT OF AGRICULTURE

BUREAU OF AGRICULTURAL ECONOMICS

Dr. JOHNSON. This chart shows the same employment in agricultural index as the previous chart did, but the other two lines, the total agricultural production and production per worker, are made up in terms of the output from acres in crops and the output in numbers of livestock; in other words, the total physical crop. That goes up rather constantly throughout the period with the exception of the severe drought years which are outstanding here, 1934 and 1936. You will note also that total output is the highest, and production per worker in terms of output is also higher, in the latter period than at any other time.

Dr. LUBIN. What is the difference between the two charts? When you talk about size of farm enterprise are you talking in acreage or values?

Dr. JOHNSON. In acreage and numbers, in terms of acreage in crops and numbers of livestock. In the last chart we are talking in terms of bushels of wheat, pounds of cotton, pounds of butter, and so on.

Dr. LUBIN. In other words, you are getting a larger yield per acre?

Dr. JOHNSON. We are getting a larger yield per acre, especially in recent years. The corn crops have been very high in yield per acre, the cotton crop has been high in yield per acre.

Dr. LUBIN. Which then would be the better measure of productivity? I noticed in your earning charts you talked in terms of the number of hours per acre. I take it that would cover the preceding chart, namely the relation of employment in agriculture to the size of the agricultural enterprise. Wouldn't the former chart be the better index of what has actually happened to productivity?

Dr. JOHNSON. The acreage chart?

Dr. LUBIN. Yes, the acreage and numbers.

Dr. JOHNSON. Of course, production varies more from year to year—that is especially true of crops—than does acreage, and therefore the acreage measure is a more stable measure. I should say that we need both in order to get the picture.

Dr. LUBIN. I mean, in one case, you are dealing with a fortuitous element. If you haven't got a rain and good weather conditions, you get a big crop and get more off that acre than you otherwise would, but in the preceding chart, you are dealing with the actual size of the enterprise, the number of acres taken care of and number of livestock taken care of.

Isn't that really the best measure of what the productivity of labor is? If, by the use of better fertilizer, you get more of that production, that isn't attributable to the workers or—

Dr. JOHNSON. My reply would be that it is a more stable measure, but that we do need to look at this other measure, too, because there has been an increase in yields per acre and output per man-hour.

Dr. LUBIN. Isn't it rather significant, however, and your preceding chart shows an actual decline in the efficiency of labor on farms, and as a matter of fact, for the year, the last year on your chart, which I think is 1939, we are way below—

Dr. JOHNSON (interposing). It is 1938.

Dr. LUBIN. We are way below any point since 1914.

Dr. JOHNSON. Yes, because of the drought influence, and in small part because of acreage adjustment programs.

Dr. LUBIN. But if you take that whole period, however, let's take the peak of 1930 and 1931, you were slightly above where you were in 1918—hardly any above.

Dr. JOHNSON. Yes.

Dr. LUBIN. So that in terms of the amount of territory covered, as it were, and livestock taken care of, there has been relatively little increase since the war years in the efficiency of labor on farms, as measured by the size of the enterprise handled per worker.

Dr. BEAN. I think you need to take into account the size of enterprise as it would have been if you had not had adjustment programs in effect, do you not?

Dr. JOHNSON. Yes; and also the drought.

Dr. LUBIN. That would apply to any economic activity, the production policy of a given industry—in other words, the policy of some industries of cutting down on production when prices fall.

Dr. BEAN. If you put it on production per factory and if you defined the industrial plant in terms of the number of factories involved, and you put two out of use because of a depression, I think you might have the same sort of showing you have here.

Dr. ANDERSON. If in the previous charts you used a bushel, or production, basis, instead of an acre basis, you got an accentuated pic-

ture, didn't you? You got an increased productivity which corresponded to the last presentation you have made.

Dr. JOHNSON. That is correct. In any area where the yield per acre grows during the period that will be true.

Dr. ANDERSON. Is it possible to distinguish between the effects upon productivity of these natural factors of climate and weather conditions, man's increased productivity due to mechanization?

Dr. JOHNSON. Well, it is very difficult to isolate the effect of the two.

Dr. ANDERSON. In other words, both are included in this chart.

Dr. JOHNSON. That is correct, because even the acreage harvested was reduced on account of the drought.

PROSPECTS FOR INCREASED EMPLOYMENT

Dr. ANDERSON. Granted this increased productivity per worker employed, and the absorptive powers of the market which I presume will be discussed, do you expect an increased or decreased number of workers on the farm?

Dr. JOHNSON. I think the evidence points toward a decrease.

Dr. ANDERSON. Do you attribute much of that to the technological change which has occurred?

Dr. JOHNSON. Yes; I would say quite a little. The evidence as we have had it presented by types of farms, on the wheat farms, and the amount of labor used in wheat production in the different areas—

Dr. ANDERSON (interposing). In other words, a summary chart such as Exhibit No. 2660 conceals very important and vital information concerning productivity increases?

Dr. JOHNSON. Well, I wouldn't say that it conceals—

Dr. ANDERSON (interposing). Fails to reveal, let's put it.

Dr. JOHNSON (continuing). Productivity increases. I would say that it fails to differentiate between increases in productivity per worker due to technological developments, and increases due to other causes.

Dr. ANDERSON. And it fails, of course, to distinguish vital movements and changes that might be occurring in such a crop, for example, as corn or cotton, or has occurred in wheat?

Dr. JOHNSON. Yes.

Dr. ANDERSON. And it would also fail to distinguish such differences by geographical areas, and the impact of such changes on particular localities?

Dr. JOHNSON. Right.

Dr. ANDERSON. It won't tell us the story of the depressed condition of the Dakotas, for example?

Dr. JOHNSON. No.

Table I, the next exhibit here, has already been discussed by Mr. Holcomb, so we will pass over it.

Dr. ANDERSON. Is that already in the record?

Dr. JOHNSON. It is already in the record in Mr. Holcomb's testimony, for a longer period.

The next chart begins the last phase of the testimony and percentage.

Dr. ANDERSON. Combined investment in work stock, machinery, and mechanical power on farms operated with horses and tractors.

(The chart referred to was marked "Exhibit No. 2662" and appears below.)

EXHIBIT No. 2662

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

COMBINED INVESTMENT IN WORK STOCK, MACHINERY AND MECHANICAL POWER ON FARMS OPERATED WITH HORSES AND TRACTORS

U. S. DEPARTMENT OF AGRICULTURE

BUREAU OF AGRICULTURAL ECONOMICS

EFFECT OF MECHANIZATION ON INVESTMENT

Dr. JOHNSON. This phase of the testimony is concerned with the effect of mechanization on investment in the farm business, largely, of course, in the part of investment represented by machinery and mechanical power, and different both in the amount and the nature of the operating expenses that result. We have taken here again some typical situations.

The first is an Iowa Corn Belt farm of 160 crop acres, on April 19, 1937. The equipment investment on farms using horses for power and horse equipment (which includes work stock) is less than for the Corn Belt farms of the same size that used tractor power and tractor equipment. It should be said, however, that those farms actually had more equipment. In other words, when they bought a tractor, they bought a combine, perhaps, to go with it, or a corn picker, so that they actually had more equipment, and part of the increased investment in equipment made it possible for them to reduce the amount of the contract work or hired labor on that farm, such, for instance, as threshing.

Acting Chairman WILLIAMS. Does your term "traitor" there include the investment of all the equipment that goes with it, or just confined to the tractor alone?

Dr. JOHNSON. No, no.

Acting Chairman WILLIAMS. It includes all the equipment to go with it?

Dr. JOHNSON. It includes all the equipment to go with it, with its present value of work stock, machinery, and mechanical power on those farms.

Acting Chairman WILLIAMS. It is contrasting horsepower formerly used on the farm with the mechanized farming of the present.

Dr. JOHNSON. It is contrasting the farms of that same size that used horses in 1937, and had horse equipment, with the farms that used tractors and had tractor equipment, as of the same date, the same sized farm.

Acting Chairman WILLIAMS. Do you mean, now, that is the investment in the animals, in the one case, and in machines in the other?

Dr. JOHNSON. It is the total value on both kinds of farms. It is the total present value of horses, if they had them, and most of them do, you see, even though they have tractors—horses, tractors, and other machinery.

Mr. PIKE. There would be different types of plows say, if you had horses, and if you had tractors?

Dr. JOHNSON. That is right; yes.

The next situation, then, is on small grain farms. We had to go back to 1931 for a comparable situation; that is, where we could compare horses with tractors in a small-grain area, because mechanization is just about complete in the wheat-producing areas. We took there a comparison for South Dakota, 360 crop acres, and again you will notice that the tractor-operated farms had a larger present value of investment in their work stock, machinery, and mechanical power than did the horse-operated farms.

You will find a little different situation on a Mississippi Delta cotton plantation. This represents a fairly large business, of course—750 acres—and the data are for 1937. When you take the present value of work stock, machinery, and mechanical power on such a plantation, you will find that the mules represent a very important part of the investment and that therefore the actual present value of that part of the plantation investment represented by those items is larger on mule-operated farms than it is on the tractor-operated farms.

Mr. PIKE. Would it be fair to guess that in general the differential in investment against this mechanized farm increases as the size of the farm decreases? In other words, with the small farm, your added acre, let's say, would be rather larger than if you could split it—

Dr. JOHNSON. I didn't have any evidence readily available, but my own judgment is that on a smaller cotton farm you would have a larger investment resulting from the use of tractor power.

Mr. PIKE. You probably won't be able to make as full use of your mechanization on a small farm.

Dr. JOHNSON. That is correct. I might add another statement to that, and that is that on a good many farms and in a good many types of farming areas, and on a good many different kinds of farms, when you add a tractor, and when you substitute a tractor for horsepower and the complementary equipment that goes with the tractor, you have capacity for operating a larger acreage than you had before. Consequently, there is a constant pressure because of unused capacity for attempting to increase the number of acres operated per farm.

Dr. ANDERSON. These displays are made up on the basis of actual farms that were in operation on the dates mentioned?

Dr. JOHNSON. Oh, yes.

Dr. ANDERSON. In the same area, and covering how many farms, say, in the Iowa Corn Belt farm under review here?

Dr. JOHNSON. I cannot answer that. Can you, Mr. Kifer—how many farms are covered?

Mr. KIFER. I can't tell you exactly how many farms there were of this particular size, but I think it was something like 56 or 60.

Dr. ANDERSON. So that you take it to be typical of what occurred?

Mr. KIFER. I think the sample was large enough so that the average was reasonably stable. The group of South Dakota farms included a few more than 100.

Dr. ANDERSON. Do you comment on the substantially larger margin of difference there between tractor-operated farms and horse-operated farms in the Corn Belt as compared with the other two, the difference in cost being, say, five-hundred-odd dollars?

Dr. JOHNSON. Yes.

Well, I would expect that the relationship would be in that direction. I would not make a great point of any wide disparity.

The next exhibit is a table showing comparative costs in operating a 320-acre wheat farm with horses and with tractors.

(The table referred to was marked "Exhibit No. 2663" and is included in the appendix on p. 17444.)

Dr. JOHNSON. This shows the operating expenses in terms of cash outlay, broken down by direct crop expense and other expense, machinery, replacement, the total charges, and receipts, and the difference between the cash farm receipts and expenses, including machinery replacement.

Hired labor expense is reduced materially. The threshing expense disappears, but there is an increased expense for machinery, repairs, fuel, and oil. Total cash expense increased somewhat; machinery replacement, depreciation charge on machinery considerably increased.

There is an increase of income from wheat because more wheat is produced.

The difference between cash receipts and the expense is indicated as approximately the same, so that one offsets the other. A higher investment in equipment is shown.

That doesn't quite tell the full story, because the significant difference to the wheat farmer is that the expense for operating and replacing equipment is no longer a variable cost, varying directly with his production, and consequently with his income. The necessity for meeting these payments in years when incomes are low, because of low prices or drought, has added to the agricultural distress in drought areas. I mentioned a moment ago that, of course, when this change takes place on a half section farm of this size, there is some unused capacity, so that in good years this farmer will have that inducement for renting or purchasing additional land, and increasing the size of his business, which in good crop and price years would be profitable for him.

COMPARATIVE COSTS OF OPERATION

Dr. JOHNSON. The next table shows the comparative cost of operating a 200-acre Corn Belt farm with horses and horse equipment as compared with tractor and tractor equipment.

(The table referred to was marked "Exhibit No. 2664" and is included in the appendix on p. 17445.)

Dr. JOHNSON. We find here approximately the same changes in expenses; a decrease in direct crop expense, a decrease in hired labor, an increase in expense for operating equipment, an increase in machinery replacement expense, and some increase in receipts, so that there is a slight increase in the difference between receipts and expenses, and a small increase in investment in equipment and horses.

The next table shows the comparative expenses of operating plantations in the Mississippi Delta situation, with croppers and mules, with wage hands and mules, and with wage hands and tractors.

(The table referred to was marked "Exhibit No. 2665" and is included in the appendix on p. 17445.)

Dr. JOHNSON. The first column shows the cash outlay and the depreciation for work stock and equipment, and the net income to the plantation for the investment in the business as well as for labor and management. The first column shows figures for operation with cropper labor and mules, the second column with hired labor rather than cropper labor, but operating with mule equipment, and the third column with hired labor and tractor power.

Now, for the situation that prevailed in 1938, with the prices that prevailed at that time, a very considerably higher net income to the plantation would result from operating with hired labor and tractor power. More cotton could be produced, by the way. There would be a reduced number of families on the plantation. That comparison is for a situation with a picking charge at 90 cents per 100 pounds of seed cotton, and other labor at \$1 a day.

The last table compares the net plantation income under two different systems with different prices of cotton and different wage rates. The first comparison, with cotton lint selling for 12 cents a pound, labor \$1 a day, and the yields as above, 350 pounds of lint per acre, shows a very considerable advantage of operating with wage hands and tractors. When labor is raised to \$1.50 a day, with the price of cotton remaining the same, that advantage of operating with wage hands and tractors is very much reduced. With cotton down to 6 cents a pound and labor \$1 a day, a plantation operator would lose less money by operating with cropper labor and mule power than he would by operating with wage hands and tractor power. If labor were 50 cents a day, the situation would be reversed, and it would pay him to shift to wage hands and tractors.

(The table referred to was marked "Exhibit No. 2666" and is included in the appendix on p. 17446.)

Dr. ANDERSON. Mr. Chairman, might we break for lunch and come back?

Acting Chairman WILLIAMS. I suppose you have concluded with Dr. Johnson. We appreciate your statement.

The committee will be in recess until 2:30.

(Whereupon, at 12:50 p. m., a recess was taken until 2:30 p. m. of the same day.)

AFTERNOON SESSION

The hearing was resumed at 2:45 o'clock, upon the expiration of the recess, Senator O'Mahoney, the chairman, presiding.

The CHAIRMAN. The committee will please come to order.

Dr. ANDERSON. Mr. Chairman, we are proceeding with the remainder of the testimony from the Department of Agriculture experts.

We have composed them into a panel for this purpose, each giving his testimony with as few interruptions as possible, and they are going to remain thereafter for questioning on the entire day's testimony.

There are two witnesses this afternoon, Mr. Louis Bean and Mr. Norman J. Wall. Mr. Wall will proceed next. He is head of the Division of Agricultural Finance of the Bureau of Agricultural Economics of the Department.

The CHAIRMAN. Mr. Wall has appeared before us before. You may proceed.

TESTIMONY OF NORMAN J. WALL, DIVISION OF AGRICULTURAL FINANCE, BUREAU OF AGRICULTURAL ECONOMICS, DEPARTMENT OF AGRICULTURE, WASHINGTON, D. C.

Mr. WALL. During the forenoon you listened to the exposition which showed the great increase in productivity in agriculture. During this same time there was also a very rapid rise in farm-land values, which was the basis for a large increase in farm-mortgage indebtedness.

The CHAIRMAN. Would you mind summarizing for me, because I was absent attending the Committee on Appropriations this morning, the story of the increased productivity of agriculture?

Mr. WALL. I am sorry, Senator, but I was also absent.

The CHAIRMAN. Well, then I will read the record.

Mr. WALL. This chart shows that there has been a very substantial increase in farm-mortgage indebtedness from 1910 to about 1934.

(The chart referred to was marked "Exhibit No. 2667" and appears below.)

EXHIBIT No. 2667

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

TOTAL FARM MORTGAGE DEBT AND RATIO OF DEBT TO VALUE OF FARM REAL ESTATE, UNITED STATES, 1910-39

Mr. WALL. Farm-land values, however, rose more rapidly, and as consequence the ratio of debt to value did not show as large an increase in the total farm-mortgage debt in the 1920's. However, the situation was reversed; as you will note that total farm-mortgage debt continued to decline, but the ratio of debt values stayed at practically a constant value during the period. Farm-land values also declined.

You will note the high peak in the ratio of debt to value in 1933, at which point it amounted to 28 percent of the total value of farms, and since that time, it has been reduced to about the level of the twenties.

Representative WILLIAMS. You are talking now about the entire farm values, as compared with the entire farm-mortgage indebtedness; is that true?

Mr. WALL. That is right.

Representative WILLIAMS. Are you going to show later on, or have you the figures there, to show the relation of the farm debt to the farms upon which the debt is placed?

Mr. WALL. We do have some information on that, showing the ratio of debt to value, which I can supply for the record, if you wish. Of course, it is much higher on the mortgaged farms. About 34 percent of all farms are mortgaged, so you can see that the ratio of debt to value on the mortgaged farm would be substantially higher.

Representative WILLIAMS. Oh, yes, undoubtedly. I was just wondering about what that was, whether it was 65 or 80 percent?

Mr. WALL. Well, I would judge, just offhand, that it might run around 50 percent.

The CHAIRMAN. Now, to explain this chart, which I understand you want to admit to the record?

Mr. WALL. Yes, sir.

FARM INDEBTEDNESS AND FARM VALUES

The CHAIRMAN. It represents, in a solid line, the curve of the farm-mortgage debt of the United States from 1910 to the present time, in terms of dollars.

Mr. WALL. That is correct.

The CHAIRMAN. And in the dotted line, it represents the ratio of debt to the value of the farm property mortgaged, in terms of percentage.

Mr. WALL. The value of all farms, including those not mortgaged.

The CHAIRMAN. All right. The chart represents the ratio of the entire mortgage debt to all of the farms in the United States.

Mr. WALL. That is correct, Senator.

The CHAIRMAN. In terms of percentages?

Mr. WALL. That is correct.

The CHAIRMAN. The dollar scale appearing at the left-hand side and the percentage on the right-hand side.

Mr. WALL. That is correct.

The CHAIRMAN. So that it would appear that in 1915, when the farm mortgage debt amounted to about \$5,000,000,000, that debt was approximately 12½ percent of the value of all the farms in the United States; is that correct?

Mr. WALL. That is true.

The CHAIRMAN. In 1930 the farm debt amounted to almost \$10,000,000,000, and the percentage had risen to 20 percent?

Mr. WALL. That is correct.

The CHAIRMAN. Then there was a very sharp rise between 1930 and 1934 of the ratio of debt to value?

Mr. WALL. From 1930 to 1933.

The CHAIRMAN. In 1931 or 1932, the ratio for the first time went above 21 or 22 percent.

Mr. WALL. Yes.

The CHAIRMAN. And it is now back to about 20 percent?

Mr. WALL. That is correct.

The CHAIRMAN. That shows a trend of reduction of the farm mortgage debt at the present time, and likewise of the ratio.

Mr. WALL. And a lower level of land values as compared to the twenties.

The CHAIRMAN. There is nothing on this chart to indicate any lower level of land values, is there?

Mr. WALL. "Exhibit No. 2668" is a short table showing the mortgage debt, the value of farm real estate, and ratio of debt to value. In 1935 the value of all farm real estate was about \$35,000,000,000, which is lower than at any time during the twenties.

(The table referred to was marked "Exhibit No. 2668" and is included in the appendix on p. 17446.)

The CHAIRMAN. Yes; but in 1933 the value of farm real estate was only \$30,724,000,000.

Mr. WALL. That is correct.

The CHAIRMAN. Which was far lower than it was in 1910.

Mr. WALL. Yes, sir.

The CHAIRMAN. And it has been increasing since that time?

Mr. WALL. That is right.

The CHAIRMAN. Now, what have you to say about the future as indicated by these trends?

Mr. WALL. It is probable that the total farm mortgage debt will not decline much further, assuming that we have a reasonable prosperity in agriculture. In other words, we would rather look for an increase in farm mortgage debt as the acquired farms of leading lending agencies are sold back to farm operators.

The CHAIRMAN. You think we can make that assumption?

Mr. WALL. Well—

The CHAIRMAN. Of a reasonable prosperity in agriculture?

Mr. WALL. That is up to Congress. [Laughter.]

The CHAIRMAN. Oh, I wish it were. [Laughter.] It would be settled tomorrow. Don't you agree with me on that, Congressman?

Representative WILLIAMS. Yes; but I won't say what I think. I would like to say it off the record. [Laughter.]

Let me ask you a question in connection with this. There has been an actual reduction in the farm indebtedness from about \$11,000,000,000 to \$7,000,000,000.

Mr. WALL. That is right.

Representative WILLIAMS. Along what line has that been? Has that been the result of foreclosures, scaling down of the indebtedness between the mortgagor and mortgagee or simply the paying off of the indebtedness?

Mr. WALL. I think it represents a combination of all those factors.

Representative WILLIAMS. What has been the main factor?

Mr. WALL. In the period from 1930 to about 1934, I think perhaps the major factor was the liquidation of debt through foreclosure and assignment, yet we find from our studies that in certain areas where income has been fairly favorable there is a fairly sizeable amount of loans liquidated through payments. There is another factor of increased debt put on for one cause or another, so that you have a combination of several factors there. Of course, debt adjustment was another factor, particularly during the period of commercial financing of the Farm Credit Administration, but I would judge that if you were going to single out any one single factor, it probably would have been foreclosure.

Representative WILLIAMS. Have you those separate figures, the figures which would indicate the extent which each of these factors played in that farm-mortgage reduction?

Mr. WALL. It would be difficult to give you exact figures because there are so many outstanding factors. We could put into the record some indications of the different factors, such as foreclosures and new loans closed, which would tend to give you a fair picture of the situation. We do come to some material later on in the exhibit that does have some bearing upon that.

The next table shows a break-down of the total farm-mortgage indebtedness by geographic divisions.

(The table referred to was marked "Exhibit No. 2669" and is included in the appendix on p. 17447.)

Mr. WALL. I think the most significant thing the table brings out is the change in the importance of the West and the South during the 30-year period. The North Atlantic States accounted for roughly 11 percent of the entire farm-mortgage debt in 1910, as compared with 8 percent in 1939. On the other hand, the Southern States, which accounted for only 16 percent of the total in 1910, now account for about 22 percent of the total. The Western States now account for about 17 percent, as compared with 8 percent in 1910.

The CHAIRMAN. This is the table representing the estimated amount of farm-mortgage loans outstanding by geographic divisions.

Mr. WALL. It is merely a break-down of the heavy black line which you see on the chart before you.¹

The CHAIRMAN. How were these figures obtained?

Mr. WALL. The estimates of farm-mortgage indebtedness are based upon the data for the known sources, that is for the Federal land banks, life-insurance companies, commercial banks, and State credit agencies, and in addition to that a W. P. A. study was conducted in which data were obtained on farm mortgages filed and recorded in the several hundred agricultural counties, and these were used to estimate the loans other than those of the known agencies. Then in each census period, the Census Bureau obtained a figure on the total amount of debt on owner-operated farms, and on the basis of this information and special surveys we develop estimates for debt on part-owned farms and on tenant farms, so that the other data are linked to the census dates as bench marks.

¹ See "Exhibit No. 2667," supra, p. 16963.

The CHAIRMAN. What is the significance of this division into regions? Is there very much significance in the table without figures to accompany this table indicating the value of farm lands in those same areas?

Mr. WALL. I think that is a very good point, Senator. I have right before me a chart which we do not include in the exhibit which shows that the rise in land values in the five divisions, Mountain States, Pacific States, South Atlantic, East South Central, and West South Central States, has been much more rapid than in other sections of the country or for the United States as a whole, and that in part explains why there has been a more rapid increase in mortgage debt in these geographic divisions. These are the sections of the country which have been developed very rapidly during the last three decades, and as a consequence have provided a greater amount of security for obtaining loans.

The CHAIRMAN. So that increasing debt in a particular region might only be an indication of increasing values.

Mr. WALL. Increasing development of that particular area.

FARM OWNERSHIP AND OPERATION

Mr. WALL. The next chart deals with the percentage of the value of farm real estate belonging to the farm operator, United States, for census years 1890-1935, and by States, 1930 and 1935.

(The chart referred to was marked "Exhibit No. 2670" and appears on p. 16968. The statistical data on which this chart is based are included in the appendix on p. —.)

Mr. WALL. You will note at the top of this chart several black bars, which indicate the percentage of the value of farm real estate belonging to the farm operator, and there has been a very significant trend in this series from 1890 to 1935. In the earlier period, the equity of the farm operators in their real estate was 59 percent of the total value of that farm real estate, while in 1935 it represented only 39 percent. In the two maps you will note the differences by individual States from 1930 to 1935, and during this period there was also a decrease in the equity from about 41 to 39 percent. This decrease occurred in practically every State. Only about six States showed slight increases. The decrease in equities during the 5-year period were particularly marked in some of the Mid-West States, where there had been a high ratio of debt to value, and a sharp drop in farm income caused a very large number of farms to come under foreclosure.

Mr. O'CONNELL. When you refer to the equity of this group, do you mean the percentage of the total of farm property that is at present owned by the farm operators, or do you mean the equity of individual farmers as against the value of the property?

Mr. WALL. This refers to the total value of farm real estate, and refers only to the equity of owners. In other words, it excludes the mortgage debt. It is the equity of owners, compared to the total value of farm real estate.

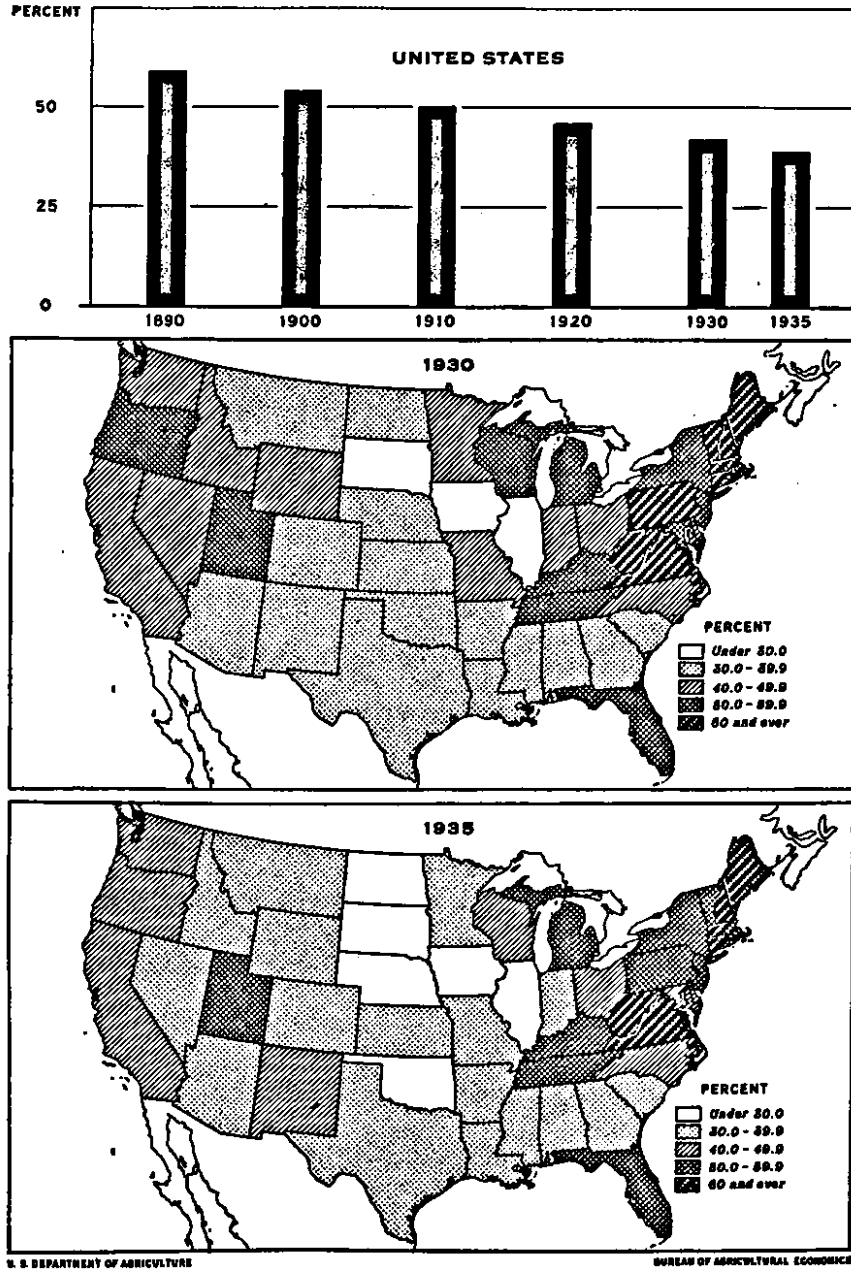

The next table shows a breakdown.

(The table referred to was marked "Exhibit No. 2671" and is included in the appendix on p. 17448.)

EXHIBIT No. 2670

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

PERCENTAGE OF THE VALUE OF FARM REAL ESTATE BELONGING TO THE FARM OPERATOR, UNITED STATES, FOR CENSUS YEARS 1890-1935, AND BY STATES, 1930 AND 1935

Dr. LUBIN. Do you mean the figures for 1930 and '35 refer to the value existing in those years of all farm real estate that is owned, or do you use a fixed base for both periods?

Mr. WALL. It refers to the value of farms in each of those periods.

Dr. LUBIN. So despite the fact that the values in these farms went down, the equities went down as well.

Mr. WALL. More rapidly.

If there are no further questions on that particular chart, we will turn to the table entitled "Total farm mortgage debt and amounts held by principal lender groups, January 1, 1910-39.

(The table referred to was marked "Exhibit No. 2672" and is included in the appendix on p. 17449.)

Mr. WALL. I think the chief significance of this table is to indicate that there has been a rapid shift of the mortgage indebtedness into the hands of the centralized lending agencies and out of the hands of individual investors.

(Representative Williams assumed the chair.)

Mr. WALL. For instance, on January 1, 1939, the land banks and the Land Bank Commissioner, life insurance companies, and commercial banks held about 60 percent of the entire farm mortgage debt. Individuals and others held about 40 percent of the total, as compared with 75 percent in 1910. A large part of this shift to the centralized lending agencies, of course, represents the substantial increase in the holdings of the Federal land banks and Land Bank Commissioner as a result of the emergency refinancing program following 1933 and 1934. Life insurance companies have reduced their outstanding loans by more than one-half in the past 10 years; commercial banks have shown a very substantial reduction, and the joint stock land banks, which are now in liquidation, of course, have shown the greatest decrease of any of these groups.

The picture of the indebtedness situation of the American farmer, however, is incomplete if we consider solely the farm mortgage indebtedness, as in addition to such debts he also borrows various amounts from commercial banks, government sponsored agencies, individuals, and others.

The next chart which you see before you, "Short-Term Loans to Farmers Held by Commercial Banks and Federal Agencies, Compared with Index of Prices Received by Farmers," will give you a picture of the changes that have occurred in non-real estate debt of farmers.

(The chart referred to was marked "Exhibit No. 2673" and appears on p. 16970.)

Mr. WALL. There has been an even more drastic reduction in personal and collateral loans to farmers held by commercial banks than there has been in the farm mortgage indebtedness. On December 31, 1920, commercial banks held commercial and collateral loans to farmers in the amount of about \$3,870,000,000. By the end of 1936 this had been reduced to about \$593,000,000, and since that time there has been an increase of about 100 percent, but this has represented largely commodity loans under the Commodity Credit Corporation loan program. The loans from federally sponsored agencies of the character similar to those made by commercial banks, which are indicated in the chart as of bankable quality, now amount to about \$195,000,000,

or roughly about one-fifth of the loans held by commercial banks. This type of loan has not increased materially since 1934. The biggest increase was in 1931-32, when the regional Agricultural Credit Corporations were established to cope with the emergency that existed in agricultural areas at that time. There has been, however, a very substantial increase in another type of loan made by Federal agencies, and that is represented primarily by emergency crop and feed loans, rehabilitation loans, and loans made to stabilize the prices of agricultural commodities, the latter under the Commodity Credit Corporation loan program.

EXHIBIT No. 2873

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

**SHORT-TERM LOANS TO FARMERS HELD BY COMMERCIAL BANKS
AND FEDERAL AGENCIES, COMPARED WITH INDEX OF
PRICES RECEIVED BY FARMERS**

U. S. DEPARTMENT OF AGRICULTURE

BUREAU OF AGRICULTURAL ECONOMICS

We might make a rough estimate of the total indebtedness of American agriculture, which would be roughly about \$10,000,000,000, representing about \$7,000,000,000 of farm mortgage indebtedness, about \$2,000,000,000 of short-term loans obtained from commercial banks and Federally-sponsored agencies, and the balance of roughly 1,000,000,000 representing loans obtained from individuals, amounts owed to merchants and dealers, and so forth.

You will note that we have charted the index of prices received by farmers along with the data for the short-term loans, and it will be noted that as prices rise there is a general tendency for the volume of agricultural loans of this character to expand, and conversely, when prices decline, there is a consequent reduction in the volume of that type of loan.

Changes in farm income naturally result in a change of the value of the collateral that the farmer has to offer in obtaining credit, and also influence his ability to repay advances already obtained.

Dr. LUBIN. Mr. Wall, do these figures include short-term loans in the sense that they represent debts of farmers for purchases of equipment, in other words, if the financing is done by the selling agency rather than the bank?

Mr. WALL. No; they would not, these are direct loans to farmers. If the advance were financed through, say, an implement manufacturer who, in turn, obtained credit from a commercial bank, that would not be in these figures, but would be in this rough catchall figure of \$1,000,000,000, that I mentioned a moment ago.

Acting Chairman WILLIAMS. What, taking the entire farm indebtedness, is the indebtedness of the farmers at the present time, compared with what it was at the peak, its highest point?

Mr. WALL. Well, I would say about \$15,000,000,000, compared with \$10,000,000,000. It was up around \$15,000,000,000 in the very early twenties. Then, as the mortgage indebtedness increased following 1920, there was some refinancing of short-term loans which didn't represent an increase in the total debt but merely resulted in a shift from the short-term category to the long-term category.

That likewise occurred to some extent following 1933; the increase in loans, we will say, of the Farm Credit Administration represented a refinancing of a considerable amount of short-term indebtedness.

Acting Chairman WILLIAMS. There has been, roughly, then, a decrease of \$5,000,000,000 in farm indebtedness.

Mr. WALL. Yes; as a rough figure.

Acting Chairman WILLIAMS. What about the rate of interest during that same period of time? How does the entire interest load which he carries now compare with what it did at that time?

Mr. WALL. Well, I have with me material on the total farm mortgage interest payments. I do not have immediately available the interest payments on the short-term indebtedness. In 1922 total interest charges on the farm mortgage indebtedness amounted to about \$680,000,000, and in 1938 that had been reduced to about \$357,000,000. That represents, of course, a substantial reduction in the mortgage debt, but also some decrease in the rate of interest.

FARM INTEREST RATES

Mr. WALL. For instance, the average rate of interest paid on outstanding farm mortgages in 1923 was 6.35 percent, and in 1939 that had decreased to 4.99, or about 5 percent. There has also been a reduction in interest rates and short-term indebtedness to the increasing proportion of short-term indebtedness held by Federal agencies, of course, reduces the average rate in all outstanding short-term indebtedness, and we know from fragmentary data that commercial banks have also reduced quite sharply, particularly in some areas, the interest rates that they charge farmers on personal collateral security.

Acting Chairman WILLIAMS. It would appear from that that the interest load today was perhaps not over half what it was in the early twenties.

Mr. WALL. Well, the relation of farm mortgage interest payments to farm income is about the same now as it was in the pre-war period, 1909 to 1914. The next table shows total farm real-estate taxes and farm-mortgage interest payable, and the percentage they form of cash

farm income. In 1938 the total of both taxes and interest charges represented about 9.5 percent as compared with 6.4 percent in 1910, but that increase in percentage is accounted for largely by an increase in farm taxes in relation to farm income.

(The table referred to was marked "Exhibit No. 2674" and is included in the appendix on p. 17450.)

Dr. LUBIN. Mr. Wall, in your previous charts you have an item called "Loans of bankable quality held by Federal agencies." You mentioned emergency legislation in the early thirties. Are there any Government sources to which a farmer can go for a so-called commercial loan of a bankable quality that will make loans today?

Mr. WALL. Yes, indeed. There are something over 500 production credit associations located throughout the United States, in which farmers can obtain credit on good collateral at interest rates around $4\frac{1}{2}$ percent per annum. These production credit associations cover the entire United States.

Dr. LUBIN. Evidently the number of loans they have been making since the value of loans has not been increasing, judging by these borrowers, but has held more or less the same since 1936?

Mr. WALL. That is just about right. I have before me some figures here for December 1936, \$172,000,000; and in 1938, \$181,000,000; in December 1939, \$194,000,000. Of course, these are year-end figures, at which time such loans are lower than they are in the middle of the year, which is the peak season for short-term advances.

Dr. LUBIN. Does this mean that commercial banks are meeting their needs, so they don't have to have recourse to these commercial credit agencies?

Mr. WALL. Well, there are a number of factors involved there. In some areas the commercial banks are giving very active competition in obtaining loans of this sort, so that these production credit associations have not shown as large an increase as they did in earlier years. On the other hand, there are certain areas, like the livestock areas, where the local institutions are not able to handle all the loan business, and in those areas the production credit associations have shown a very satisfactory business.

Dr. LUBIN. Are they incorporated?

Mr. WALL. Yes; each borrower must take stock in the amount of 5 percent of his loan.

Acting Chairman WILLIAMS. In that respect they parallel exactly the Federal land-bank system?

Mr. WALL. That is correct.

Acting Chairman WILLIAMS. And what about the rural rehabilitation program?

Mr. WALL. Those are direct loans made by the Farm Security Administration to farmers who cannot qualify for credit from other agencies.

Acting Chairman WILLIAMS. That is an additional agency to make these nonbankable loans?

Mr. WALL. That is right.

The next table, which is entitled "Number of Farms Changing Ownership by Voluntary and Forced Sales, Per 1,000 of All Farms, by Geographic Divisions, 1926-39," will have some bearing on the question which you raised earlier in connection with the factors that accounted

for the sharp reduction in mortgage indebtedness. The amount of forced sales rose rapidly after March 1931 and reached a peak during the year ended in March 1933, at which time they were about two and a half times the average prevailing during the 5-year period 1926 to 1930. The portion of that that is just sales has been quite large in the West and North Central States, and this is accounted for by the larger percentage of farms mortgaged, together with the relatively high rates on the mortgage debts to land values in these particular areas before the depression set in.

(The table referred to was marked "Exhibit No. 2675" and is included in the appendix on p. 17451.)

Mr. WALL. Now, if you want to see the result of all these developments, you might turn to the following table, which shows farm real estate held by leading lending agencies.

(The table referred to was marked "Exhibit No. 2676" and is included in the appendix on p. 17451.)

Mr. WALL. As a result of the depression and the large volume of forced sales, there has been a considerable shift in the ownership of farms from owners to the large lending agencies.

At the beginning of 1939 a group of five of the most important lending agencies held acquired farms in an estimated investment of slightly over \$1,000,000,000. This represents roughly around 28,000,000 acres. These holdings are largely concentrated in the Midwest States, where land values were relatively higher in other sections of the country, and with, as I mentioned a moment ago, the ratio of debt to value and percentage of farms mortgaged were both quite high before the depression set in.

Acting Chairman WILLIAMS. Are there any further questions? I think that is all; thank you.

Dr. ANDERSON. The next witness of the panel is Dr. Louis Bean. He has been previously sworn.

TESTIMONY OF DR. LOUIS BEAN, ECONOMIST, BUREAU OF AGRICULTURAL ECONOMICS, DEPARTMENT OF AGRICULTURE, WASHINGTON, D. C.—Resumed

Dr. BEAN. I should like to begin, Mr. Chairman, with the very last tabulation in that small document that was brought together.

Acting Chairman WILLIAMS. What is the title of it?

Dr. BEAN. The title of that tabulation is "Gross income from farm production, expenditures for labor, and value of farm implements and machinery on farms, by types of farms, 1899 and 1929."

(The table referred to was marked "Exhibit No. 2677" and is included in the appendix on p. 17452.)

Dr. BEAN. The purpose of this table is to give a very general impression as to the relation between expenditures for labor and the expanded use of farm machinery during the period of 30 years, 1899 to 1929, with the assumption that there will be a great deal more detailed information presented for the most recent decade.

Another reason for presenting this table is that it gives information which has not been presented so far, on the relation of expenditures for labor and machinery, by types of farms.

The contrast is presented here in terms of the expenditures for labor as estimated or tabulated by the censuses in these 2 years, as percentages of gross value of production, sometimes called the gross income from agricultural production.

Similarly, I have used the value of machinery on farms as reported by the Census, as a ratio to gross income, merely to get some indication of the changes in these two items as between types of farms and over this 30-year period, not purporting to say that this represents the situation of 1939 but merely to supply the committee with material for that 30-year period as a background for more recent data. As indicated by the testimony of this morning, much more striking changes have taken place in the past few years than took place during the earlier 20 or 30 years.

The gist of this tabulation, then, is that between 1899 and 1929, expenditures for farm labor as a percentage of gross income declined from 9.7 percent to 8.7 percent.

Dr. LUBIN. Does the series in the 1929 figure include the same things as the 1899 figure? They are labeled differently, but taken as a whole, are they the same?

Dr. BEAN. That is right. They are essentially the products of agriculture, exclusive of products fed to livestock, sometimes defined as the value of sales plus the value of products consumed in the farm home.

In that same interval, the ratio of farm machinery inventory to income increased from 20.2 percent to 30 percent.

Dr. ANDERSON. Your ratio for farm machinery is based on inventory and total gross income?

Dr. BEAN. That is right.

Dr. ANDERSON. Let me ask you, first, what does farm machinery include?

Dr. BEAN. It includes all of the farm implements plus the motor equipment that farmers have bought during the past generation or so. In other words, you had, in 1899, farm implements and machinery exclusive of the motor equipment which is now typical of farming.

Dr. ANDERSON. In other words, it would include automobiles?

Dr. BEAN. Automobiles and tractors.

Dr. ANDERSON. And trucks?

Dr. BEAN. That is right.

Dr. ANDERSON. And would it include household machinery, sewing machines, and so on?

Dr. BEAN. No; this is only machinery on farms, for productive purposes.

Dr. ANDERSON. The ratio in 1899 was 20 and in 1929 it was 30. Do you have any break-down to indicate what would make the difference?

Dr. BEAN. I will come to that a little later. We have some information on the relative increase in the purchases and costs of motor equipment.

Dr. ANDERSON. But this is an inventory figure, and would not be taken to mean in any sense the proportion of an income that would be spent for machinery—

Dr. BEAN. Not directly, only as indicative of the, say, incidence of costs for machinery in relation to gross income. Insofar as a

change in the value of inventories is representative of a change in depreciation costs.

Dr. ANDERSON. And we will discuss the detail of it later?

Dr. BEAN. I will have a little more detail on that in another tabulation.

If you will take the cash grain farms for that interval, we find that in 1899 the inventory figure increased from 21.8 percent to 46.7 percent. That is the largest increase of any of the types of farms shown here. The proportion of income paid out for labor in this group of farms declined from 10 percent in 1899 to 8.3 percent in 1929. In the case of cotton, the proportion going for wages was the same in 1929 as in 1899, namely, 5.9 percent; while the farm machinery inventory figure rose from 10.4 to 16.4 percent. Similar changes took place on dairy farms. There, wages took 13.3 percent in 1899, and 8.6 percent in 1929. Farm machinery inventories increased from 25.6 percent to 34.4 percent.

On livestock farms the shift in the wage proportion was from 8.2 to 6.2, and the machinery item increased from 19.1 to 29.5. The smallest change occurred on fruit farms. There wages took 20.1 percent of income in 1899 and 23.7 in 1929, the machinery item rose from 19.1 to 24.7.

EFFECT OF MECHANIZATION ON LABOR COSTS

Dr. LUBIN. Is it fair to conclude from these figures that in some instances the large increase in the use of machinery had little or no effect upon percentage of income that went to labor whereas in other instances the relatively small increase through this machinery affected labor costs rather markedly?

Dr. BEAN. Well, I present this material for such inferences as any of you may make, and I think you are in about as good a position to draw inferences from this as I am. I thought that you were interested in such quantitative expressions of that question as we can bring to you.

Dr. LUBIN. Evidently the table shows that a 50-percent increase in machinery inventory resulted in about a 9-percent decline in the amount of farm income that went to labor.

Dr. BEAN. That is the over-all evidence, that you could have a substantial increase in machinery costs and not have a similar offset in the reduction in the wage bill.

Dr. LUBIN. In many instances no offset at all, in fact an actual increase.

Dr. BEAN. That is possible.

Mr. PIKE. You probably had a much higher rate of wages in 1929 than in 1899.

Dr. BEAN. All values were different.

Mr. PIKE. But the man-hour reduction doesn't show.

Dr. ANDERSON. Dr. Bean, the question I raised earlier was to fix the point you have just brought up about an increase in machinery costs. Do I take it that we can consider inventory figures as machinery-cost figures?

Dr. BEAN. Sometimes, lacking better information, it is possible to take an inventory item and allow, say, 10 percent of inventory as cost of depreciation, or some such formula; it doesn't have to be 10 percent.

It is for that purpose that I have used this over-all impressionistic ratio of inventory to gross income. I think it represents fairly well a shift or change in the relative importance of this item as a cost, not an absolute, but a relative change. I think we come a little closer in answer to your question in the next exhibit, which is called "Cash Farm Income From Marketings and Cost of Operating Farm Machinery, Depreciation, and Wages Paid for Labor as Percent of Farm Cash Income, 1910-39."

(The table referred to was marked "Exhibit No. 2678" and is included in the appendix on p. 17453.)

Dr. BEAN. The Bureau of Agricultural Economics is in the process of making estimates of items in the cost of producing the annual farm production, and I have utilized that material, which has not yet been fully published, in the form of ratios to cash income from the marketings of farm products.

The estimates of depreciation allowance on all farm machinery and farm equipment as a percentage of cash income appear in the second column, and you will notice that in the pre-war years that figure represented close to 6 percent of the annual receipts. In the post-war years of the 1920's, that percentage is something over 6 percent, between 6 and 7 percent. In 1931-32, naturally that proportion rises sharply as it did in 1921 because of the sharp shrinkage in income. In the more recent years, 1938 and '39, that depreciation ratio stands at about 9 percent.

Mr. PIKE. It is a pretty high depreciation there, better than 20 percent. The only year where it is comparable, in 1929, you had 30 percent inventory and 6.8 depreciation.

Dr. BEAN. That would be a fifth.

Mr. PIKE. Yes; you were amortizing there in less than 5 years on your farm machinery.

Dr. BEAN. These are the facts and if you would like to argue about them I will get you the reasons for them. For the moment I think all that I want you to use these figures for is to get an impression of relative change. The 5 or 6 percent before the war isn't absolutely significant, but the change from 5 or 6 before the war to 8 and 9 now I think is.

The next column represents the net cost of operating farm machinery, which is essentially automobiles, trucks, and tractors, including gasoline, tires, oil, things of that sort. And you will notice that in the pre-war years that cost was insignificant because this type of farm equipment didn't exist. In the 1920's, it had risen to over 7 percent of annual receipts, and in the last 2 years, it was slightly under 12 percent, or 11.7.

Mr. PIKE. For a man operating equipment with his own horse, you wouldn't charge that—

Dr. BEAN (interposing). No; it is cash outlay.

Dr. LUBIN. What would the percentage be now if the level of farm prices were equal to what they were in 1929?

Dr. BEAN. Farm prices now are approximately 100; in 1929 they were 50 percent higher. I suppose this ratio would drop to perhaps 8.

Dr. LUBIN. You would be close to where you were in the '20's.

Dr. BEAN. That's right. The wage proportion is shown in the next column, and here it appears that in the pre-war years farmers paid out

annually a little over 9 percent as cash wages. In the 1920's it was something under 9 percent, but not a great deal. In 1929, it was 8.5, compared with 9.1 in 1910; since then it has fallen off to 7.1 in 1939, having gone lower in 1934.

Dr. LUBIN. Do these wages include all wages on the farm or only those wages for the cost of operating machines?

Dr. BEAN. This is all wages, cash wages for hired labor. The sum of these three cost items in relation to income is in the last column, and we find here that nearly 16 percent of receipts in the pre-war years went for these three costs. By 1929, the figure amounted to 23 percent, and in the last 2 years, it has averaged 28 percent. As you study the make-up of this aggregate figure, it is clear that there has been some offset as between the increase in the depreciation column and the decrease in the cash wage column, so that the net increase in the relative importance of these three cost items is almost entirely accounted for by the increased importance in the cost of operating automobiles, trucks, and tractors.

Dr. LUBIN. Has there been an increase in the cost of operation, or an increase in proportion of income that has been devoted to it?

Dr. BEAN. All this information shows is that there has been an increase in the proportion of income going for this type of expenditure.

Dr. LUBIN. The costs may have gone down.

Dr. BEAN. Whether or not other costs have gone down to offset this is another question, and I think on that I can tell you that there have been some reductions naturally in the past few years, taxes and interest—

Dr. LUBIN (interposing). Even in operation, I mean if you had the same cash income in 1939 that you had in '29, your actual percentage of income that goes to operation of these machines would have been lower.

Dr. BEAN. Oh, naturally.

Dr. LUBIN. In other words, it isn't cost of operation that has gone up, that may have gone down for all we know, but as a ratio to total cash income—

Dr. BEAN (interposing). That is right; and I thought it was important to give you the relation of costs to income and not merely the absolute figures which you already have.

Colonel CHANTLAND. Wasn't there a figure given this morning that indicated that the farm help without the payment of wages did go up during this time at the same time that these other costs went down?

Dr. BEAN. "Exhibit No. 2648" gave the annual average of persons employed, divided into three groups, total employment, family workers, and hired workers. I have just been studying this tabulation, because I wanted to see what relation it bore to the course of the number of tractors on farms,¹ and if you wish I will give you the relation of those two.

Colonel CHANTLAND. In other words, if they did pay less wages, but had more of their own family on without paying the wages, the cost still was there, if the boy is entitled to anything.

Dr. BEAN. If you will hold that "if" for a moment, we will see if it is really pertinent.

¹ See "Exhibit No. 2655," appendix, p. 17445.

I would like to give you the figures for three separate periods. You may recall from "Exhibit No. 2655" that the number of tractors on farms rose fairly persistently from 1913 to 1939. It was pointed out that there were three periods when the expansion in the use of tractors was more marked than in other periods. We had a rapid expansion which culminated in about 1920, then you had another expansion which was more rapid than in other years, which culminated shortly after 1930, and then you had another expansion in the last few years.

CHANGES IN FARM LABOR FORCE

Dr. BEAN. I want to present the figures for your question for these three periods. Family workers, during that first period of expansion in farm machinery of this type, dropped from an index of 107 to 101, the years being 1915 to 1920. In other words, you had a 7-percent decline in family workers. During that same period you had a decline of 2 percent in hired workers.

Colonel CHANLAND. But that is family wages. Supposing they don't pay family wages, or do you figure it at any rate?

Dr. BEAN. May I first present the physical aspect of the question, numbers of people, because it underlies the problem of evaluation. That family workers declined 7 percent, hired workers 2 percent during that first period when farmers went into motor equipment fairly heavily. During the second period of expansion, which I mark off as between 1925 and 1932, over that period of 7 to 8 years there was no change in the number of family workers, the index being 102 in each of those 2 years, but during that interval family workers declined from 102 in 1925 to 99 in 1929, which is a decline of 3 percent prior to the onset of the depression, so that the subsequent increase in family workers from 99 in 1929 to 102 in 1932 is apparently a function or a result of the low prices and the depression.

During that same period, from 1925 to 1932, we have a decline in the number of hired workers from an index of 97 to 85; in other words, 12 points, or approximately 12 or 13 percent.

Now we come to the final, the most recent, period of expansion, and there, taking the period from 1935 to 1939, we find a reduction in the number of family workers of 6 points, from 103 to 97, or, roughly, 6 percent, but no change in the number of hired workers, the index being 84 in 1935 and 84 in 1939, with some increase in that interval, and a subsequent decrease. The net change over that 5-year period is zero.

So that over this period you have a reduction in the number of people producing as one of the factors in this wage bill, and at the same time I think you see the relation between the change in the number of workers to possibly one of the factors which is at least logically associated with that change.

Dr. ANDERSON. Dr. Bean, why do you select the particular periods of time that you do?

Dr. BEAN. They are selected for me by the data.

Dr. ANDERSON. Let's see that clearly, sir.

Dr. BEAN. Is it possible to get "Exhibit No. 2655" back on the easel?

Dr. ANDERSON. In other words, you are basing it upon that distribution of time? We would like to see the connection between the two sets of data.

Dr. BEAN. While the predominant record here is of a sharp increase in the inventory of tractors on farms, it is clear that the changes in that rate of expansion are an indication of the more or less rapid rate of accumulation or purchases. This curve peaks up at January 1920, indicating that there was a rapid increase in purchases or expansion in purchases of tractors. In 1922 the inventory figure was about the same, indicating that there was practically no additional purchase of tractors in that year, or at least a very small one. To put it another way, it was only enough to offset depreciation.

The next period of rapid accumulation occurred during the late 1920's, culminating with 1932, and the final, or the most recent period, occurred during the last 5 or 6 years, so I select these three periods merely because the record suggests that those are the periods when, if this has any relation to employment of farm labor, you would expect to find it in the record.

Dr. ANDERSON. Would it be possible to take, instead of the inventory of farm tractors, actual increased sales?

Dr. BEAN. I think, if you can visualize numbers of tractors around this line, you will have essentially annual purchases, assuming that you have a constant purchase for replacement, but these variations in the rate of increase of this line represent variations in annual purchases.

Dr. LUBIN. Dr. Bean, I am sorry I wasn't here this morning when the question of farm population was discussed, but evidently, judging by the tables which were submitted, and the charts, there has been a very marked increase in agricultural population in the last 15 or 20 years.

Dr. BEAN. No.

Dr. TAYLOR. Since 1932 there has been, Mr. Lubin; up to 1932 there was a gradual decline.

Dr. LUBIN. The chart here—

Dr. BEAN (interposing). That is certain groups in the farm population. That is not the total farm population. May I give you the total farm population? In 1909 it is estimated at 32,000,000; in 1920 at 30,200,000, in 1939 at 32,000,000. In other words, between 1909 and 1939 there has been no real change in the farm population. The change that you have there represents the changes in the age groups.

Dr. LUBIN. That was a 6-percent increase, roughly.

Dr. BEAN. Between 1929 and 1939 you have an increase of about 1,800,000; yes; about 6 percent.

Dr. LUBIN. The increase in your family workers, however, at the maximum, was 4 percent, is that right?

Dr. BEAN. The increase in family workers? There has been no increase in family workers.

Dr. LUBIN. Between 1929 and 1935 there was an increase of about 4 percent.

Dr. BEAN. Yes; for that period there has been.

Dr. LUBIN. Well, now, what do these people do? You have increased your population by 6 percent on farms. Do you assume that most of these people are doing nothing on the farm, that they don't help at all?

Dr. BEAN. I personally assume that they are doing very little, if anything; that some of them are on relief work and some of them perhaps are doing nothing. We have no—

Dr. LUBIN (interposing). Although you have 6 percent more people on the farm, about 2 percent less of them are working, which means they are either on relief or do nothing at all. They are not helping on the farm.

Dr. BEAN. All I can say is that we have a general impression that there is a surplus population on the land, both total and working.

Dr. LUBIN. There may be a surplus in terms that they are not necessary, but the question is, are they doing anything?

Dr. BEAN. Well, what do you think they are doing?

Dr. LUBIN. I get the impression that they have been doing odds and ends and, consequently I can't reconcile your decline in the number of family workers since 1929 with the increase of farm population since 1929. It assumes not only that everybody who went back to the farm is doing nothing, but all new additions are doing nothing, plus some others who formerly were doing something who are now doing nothing.

Dr. BEAN. Unfortunately, I don't have any qualitative impression of this thing, and I doubt if anybody has, so that whatever I say is hardly worth the saying. You might, however, assume that since a larger proportion of your population is in the higher-age groups, over 60 or above 65, perhaps they are not working as much as they used to, if they can rely on some of the folks who have come back from the cities onto the land. But that is all speculation.

Dr. LUBIN. That assumes that everybody who came back from the city, plus 2 percent more who formerly were working, are not working today.

Dr. BEAN. I don't know that it is worth while pursuing this. I don't have any information, and I don't think anybody else has, as to what this excess of population is. If they are working, then it is clear that they are not working economically.

Dr. LUBIN. I will agree with that. That we can all agree on. But I am just wondering; it seems unreal to assume that the net difference, the increase in farm population, both through migration and birth, is not doing anything—let's not use the word "employed" because that has an economic significance—plus 2 percent more who formerly were working who aren't doing anything at all.

Dr. BEAN. It is your privilege to make that assumption. I might assume something different, but I don't think either of us knows.

Dr. ANDERSON. The designation "family worker" has never been precise, and any small percentage of change would mean nothing significantly in a series of data. As a matter of fact, we are getting more improved data as we go along, but nobody would stake his life on the precise meaning of "family worker" in 1 year of collection of data as compared with another. I think that would have something to do with the interpretation to be made of the changes that have occurred.

Dr. BEAN. Your remarks lead me to add that between 1929 and 1935 there was an increase in the number of farms, and therefore presumably an increase of something like 600,000 or 700,000 persons who are engaged on these farms as part of this farm family labor group.

Dr. LUBIN. But they seem to have disappeared since '35, because you are down below where you were in 1929.

INCREASE IN FARM PRODUCTIVITY

Dr. BEAN. I think we will be a little clearer on that point as soon as we have the next census data. But this happens to be the best information we have, and roughly, the data indicate that your total farm population is the same as it was 25 years ago; there has been some increase, of uncertain magnitude, in the past few years and that all the evidence we have indicates that there are more people on the land than are now required for production.

Colonel CHANTLAND. Omitting all idea of exports, how many more people in the United States have they had to take care of during these same periods?

Dr. BEAN. You might say, very roughly, that 32,000,000 people on the land are now feeding or taking care of 99,000,000 people.

Colonel CHANTLAND. Besides themselves.

Dr. BEAN. Besides themselves; whereas in 1909 they took care of nearly 58,000,000. In other words, the same number of people on the land now feed roughly 70 percent more people. If you make one further assumption, which is not unrealistic, that over this period of years there has been no material change in the per capita consumption of food products for the Nation as a whole, the annual intake of agricultural products tends to be a pretty constant figure per person.

If that is so, then you might say that 32,000,000 people on the land today are 70 percent more productive than 32,000,000 people on the land in '99.

Colonel CHANTLAND. That is assuming that your export remains at a sort of constant factor. If it changed it would throw it out of kilter.

Dr. BEAN. We know within what period that change may take place. Before the war—I am giving you a figure from memory now—something like 18 percent of our total output went out as exports. In the past few years it has been only 7 or 8 percent.

Colonel CHANTLAND. That makes quite a difference.

Dr. BEAN. It makes a difference of 10 percent.

Dr. ANDERSON. But let's put in the import picture and see what happens. What were our imports before the war as compared with what we import now?

Dr. BEAN. I don't have that here.

Dr. ANDERSON. As I remember it, it cuts it down materially, so that 10 percent doesn't look quite like that.

Dr. BEAN. Let's put it this way: in 1909 you had 100 units of domestic consumption plus 18 units of exports; today you have 100 units of domestic production and 8 units of exports, giving you a total of 118 in one case and 108 in the other. That is a difference of 9 percent in the 70 percent figure I gave you.

Colonel CHANTLAND. But Dr. Anderson says that 108 is to be reduced by certain imports.

Dr. BEAN. Let's leave it this way.

Colonel CHANTLAND. I think we had better not pursue it because we haven't the figures.

Dr. BEAN. I would like to leave an impression as to where that figure might lie. If it isn't 70 it might be 60 or it might be 50, but

it isn't less than 50 percent increase in productivity in terms of people engaged on the land.

Colonel CHANTLAND. That is really all we can say.

Dr. BEAN. And that is, I think, the long-time history of agriculture in this country, that a fairly constant number on the land is decade by decade able to produce for an increasing industrial population, without increasing the number of people on the land.

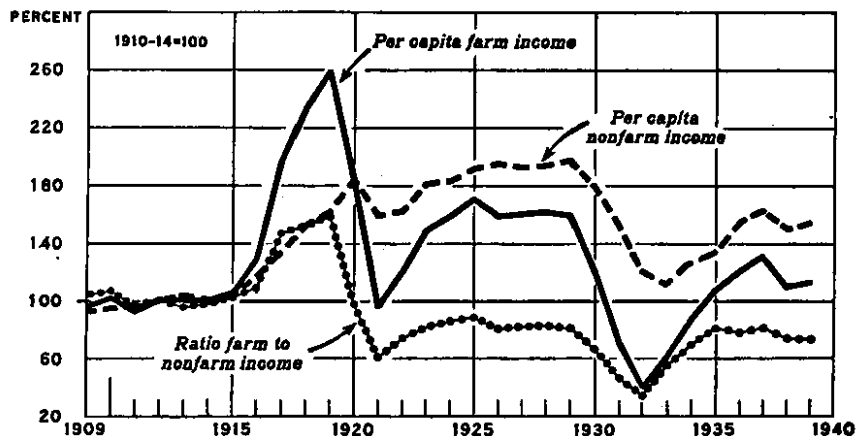

I have two items that I would like to call to your attention. One is in connection with the chart labeled "Per Capita Farm and Non-agricultural Income Available for Living."

(The chart referred to was marked "Exhibit No. 2679" and appears below.)

EXHIBIT No. 2679

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

PER CAPITA FARM AND NONAGRICULTURAL
INCOME AVAILABLE FOR LIVING, 1909-39

U.S. DEPARTMENT OF AGRICULTURE

Dr. BEAN. I want to use this material in relation to the cost items that we discussed earlier.

FARM INCOME

Dr. BEAN. There are two sets of data in this illustration. One represents the per capita income received by individuals not on farms. It is the income per person of the nonfarm population. If you will, it is the national income, exclusive of agricultural income, on a per capita basis. That is the dotted line which reaches the high point in 1929 above the other lines that you see there. The second set of data is income available to persons on the land derived from agricultural production. It is obtained by deducting from the gross income from farm output a selected list of business expenditures, including these machinery cost items that we have here before us—costs of feeds and fertilizer and building materials and various other things—so that we have here the amount of money available per person living on farms for living purposes, as contrasted with income available for business purposes.

Acting Chairman WILLIAMS. Are you talking about cash income?

Dr. BEAN. I am now talking about cash plus the value of things consumed, goods consumed in the home, derived from farming.

In 1939, the last point on the chart, income per person not on farms was roughly 156 percent of the pre-war level. Agricultural income available to people living on the land—that is, income from farm production—was approximately 120 percent of the pre-war figure, and the difference between those two is represented by a ratio of 80. In other words, had farm income been higher by the equivalent of \$1,500,000,000, the farm-income line would have been up where the non-agricultural income line is in 1929. The nonagricultural income line, incidentally, is what the Department of Agriculture calls parity income; it is the level of income of nonfarm people to which farm income would need to rise if parity income for agriculture were attained, and that difference in 1929, in addition to the Government payments made to farmers, approximates \$1,500,000,000.

Dr. LUBIN. Where would that be if you would change your base from 1915 to 1920?

Dr. BEAN. It would have to turn back and make some mental computations.

Dr. LUBIN. The farm income would be greater than nonfarm income average per capita.

Dr. BEAN. Naturally that relationship depends upon the base period selected. If you want to go into why that period is selected I will do that, but I don't think that is what you need this afternoon.

Dr. LUBIN. I am trying to find out what significance this is. If you change to a different base you find the farm income higher than that.

Dr. BEAN. If you took 1919 as a base, then, of course, farm income would be much lower in relation to other income than it is; if you took it at 1929 it might not be quite as low. Perhaps that disparity would be completely wiped out.

Acting Chairman WILLIAMS. I had the impression that when we were talking about parity we were talking about that period between 1909 and 1914 or '15. The purchasing power of the farm products as compared with the value of manufactured products would be that period on which that line seems to run about parallel from 1909 to 1915. I have always understood that when legislators talk about parity of agriculture to industry it meant that period of time.

Dr. BEAN. There are two things. This represents parity income. You are referring to parity price. In concept, they are essentially the same except that one is a price comparison and this is an income comparison. It is true that in both cases the pre-war years are taken as a point of departure, and the relationship of the pre-war years constitutes the parity relationship. The parity relationship, these two lines, may come together at any point. They may come together at 156, in which case you have restored parity. That is, one would have the same relation to the other at this higher level of 156 as they had in the pre-war years, when they were equated at a lower level.

The main point is that equation; that is, the two series of data have the same numerical value. They have been given a value of 100 before the war, and if they both should have the value of 156 in 1939, then they would have parity of income.

Similarly with prices. Industrial prices are now, speaking from memory, about 125 or 128 percent of the pre-war level; farm prices are

at about the pre-war level, so you have a discrepancy there indicated by a ratio of 80 or 82. I think 80 is the most recent figure, so that both in terms of price ratio and income ratio, we come to practically the same point in terms of the parity level.

Acting Chairman WILLIAMS. What in figures was the farm income for 1939, if you have that?

Dr. BEAN. The cash income figure was about \$8,500,000,000. A gross income figure, including the value of things consumed from farm production, would bring it close to \$10,000,000,000. In 1929, it was around \$12,000,000,000. That is gross income.

For the purposes of this comparison, it is necessary to deduct business expenditures from that gross-income figure to obtain income available to farm families for living purposes, and to make it comparable with the income of the nonfarming population, because no business expenditures or income are included in the non-farm-income line.

May I make one other observation about this discrepancy of \$1,500,000,000? In one of the previous tables, I indicated that there has been a net increase in the cost of operating farm machinery from 0.2 percent of income in 1910 to 11.7 percent in 1939. Part of that increase represents the use of automobiles for home or pleasure use as against production use so that not all of this increase of nearly 12 percent is to be associated with the increased costs of running the farms. If we assume that only about 8 percent of this increase is to be so associated, then that net increase of 8 percent is the equivalent of something like \$500,000,000 to \$600,000,000 in an annual cash income of nearly \$8,000,000,000. Six billion dollars of income represented in this column of expenditures associated with machinery is approximately 40 percent of this discrepancy between actual farm income in 1939 and parity income.

Now, I would like to turn to a table entitled "Distribution of gross farm income in each of 10 equal groups of farms arranged according to the size of income," for the years 1899 and 1929.

(The table referred to was marked "Exhibit No. 2680" and is included in the appendix on p. 17454.)

Dr. BEAN. This material has been gotten together hastily. It was done last night, so that many questions about it I may have to stall on, or ask you to give some additional time. There are additional comparisons that we need and want to make and hope that we can either present at a later occasion or for the record. As it stands, this material gives some impression as to what is happening to farm income in relation to the number of farms in the different income brackets.

You will notice that in the column marked "All farms," the number of farms up to the first 10 percent in the lowest income group there, we find less than 1 percent of the value of farm products in 1899 and a little more than 1 percent in 1929.

If you go to the other extreme and examine the income which falls in the last 10 percent of the farms associated with the higher-income brackets, namely, in a group I have marked 90 to 100 percent, we find nearly 40 percent of all farm income in that group of 10 percent of the farms in 1899 and 41 percent in 1929—in other words, a shift of 1.5 points.

As you look down the third column of that tabulation marked "Difference," it is clear that there has been some shift in income into the

lowest-income groups, and some shift into the very highest income groups. There is an additional comparison given so that you may see whether that increase in the highest income brackets took place evenly as between the last 5 percent and the next to the last 5 percent.

When you take all farms you find that the increase in the highest income bracket occurred for that bracket which I have marked 95 to 100 percent; in other words, the 5 percent of the farms getting the highest income in 1929 got a little bit more than similar farms got in 1899.

The next column is labeled "Cotton farms." Here we also find that there has been some increase, not a great deal, but some increase in the proportion of income associated with the farms in the lowest-income brackets and some decrease in the farms associated with the highest-income brackets. It is particularly in connection with this column that we want to do some more work to examine this type of data with respect to the owner-operated farms, the tenant farms, and the share-cropper farms.

Mr. PIKE. The present census will affect that.

Dr. BEAN. We are really waiting eagerly for the 1939 results. It is really in anticipation of that that we are preparing this background material.

In the case of the grain farms, the same situation appears, with a somewhat lower concentration in the grain farms, with a somewhat higher concentration in the last 5 percent of the high-income farms.

In the case of livestock, the thing which differentiates that column from the others is the increase of 7.5 points in the group of 90 to 100 percent of the farms, and there, too, the increase occurs chiefly in the last 5 percent. The most striking of these groups is the fruit-farm group. Here we have a decrease in the proportion of income for each of the income brackets except the lowest 10 percent, and a very marked increase in the last income bracket, an increase of 16.7 points in the 95- to 100-percent bracket. In the final column, labeled "Crop specialty farms," which is a catch-all, including vegetable farms, truck crops, tobacco, and sugar, we have the same general showing, that there has been an increase in the proportionate income in the low-income brackets, and only a very slight increase in the highest-income brackets.

With respect to that last column, I think it would be worth while to show that in its detail because the groups that are included here represent a great diversity. In general, then, I would say that the low income brackets have received somewhat more than the former share and that the middle income brackets have received somewhat less, but that the very high income brackets are receiving, or in 1929 received, relatively more. That fact checks also with the usual data supplied by the census on the size of farms, and just to give you a brief comparison in these terms, if you take the number of farms with 20 acres or less, we find that in 1920 there were 12.4 percent of all farms in that low acreage group.

Mr. PIKE. That is just number of farms?

Dr. BEAN. That is number of farms. In 1930, it is 14.6, an increase of 2.2. In all other size groups, there is a relative reduction similar to what I have just discussed in terms of income. When we get to the group of 500 to 1,000 acres, we find a slight increase, from 2.3 percent of all farms in 1920 to 2.5, about an 8-percent increase

relative to numbers; and in the size of farms over 1,000 acres, the proportion goes from 1 percent in 1920 to 1.3 in 1930. Also, contrasting this size of farm with the relative importance of farm implements and machinery, we find something of the same general characteristic, that in the lowest size group, under 20 acres, the value of implements and machinery rises from 3.2 percent of the total in 1920 to 4 percent of the total.

In the next size groups up to above the average, we find relative reductions, but in the group of 175 to 500 acres, the value of farm implements and machinery rises from 31.7 percent of the total in 1920 to 32.2 percent in 1930, and in the next two groups, or all the rest, above 500, the increase is from 11.3 in 1920 to 15.1 in 1930, so that you have three sets of data here, the distribution of your farm machinery by size group, the distribution of the number of farms by size, and the distribution of the number of farms by income group, which seem to present three patterns of the same general characteristics.

Mr. PIKE. You would infer some increase in corporate farming, what is happening in the larger farms, wouldn't you?

Dr. BEAN. That would be an inference but I don't know whether that is a fact.

Mr. PIKE. It isn't necessarily so but it sounds very much that way.

Dr. BEAN. It would lead one to investigate that question.

Acting Chairman WILLIAMS. What is your definition of "farm"? What do you consider "farm"?

Dr. BEAN. I have adopted the census definition, whatever it is. I think it is generally 3 acres or more, producing something like \$250 worth of goods. That figure has changed over the years, but I think between 1900 and 1929 the definition hasn't been much different.

Acting Chairman WILLIAMS. I notice you spoke of an average. Do you mean an average-size farm?

Dr. BEAN. The groups that I have here run under 20 acres, 20 to 49, 50 to 99, and 100 to 174, and the average-size farm falls within that bracket of 100 to 174 acres to a farm. It is beyond that bracket of 100 to 174 that we find a relative concentration of farm implements and machinery.

Acting Chairman WILLIAMS. Have you figured actually how many farms there are in the country?

Dr. BEAN. For 1900 the number of farms is given as 5,700,000; for 1929 it is given as 6,200,000 in rough figures, and for 1935, 6,800,000.

Acting Chairman WILLIAMS. Something was said a while ago by someone about the number of farms that were mortgaged. Have you that figure?

Dr. BEAN. Mr. Wall, who I hope is still here, had that.

Acting Chairman WILLIAMS. I don't know whether he gave the number.

Mr. WALL. It is 34½ percent of all farms.

Dr. BEAN. Which would be a third of the 6,800,000, which is 2,200,000, for a quick calculation.

Dr. LUBIN. I wonder whether you would repeat for the record the percentage of gross farm income that goes to the upper 10 percent in each of these groups.

Dr. BEAN. Do you want the contrast for each group?

Dr. LUBIN. No; just for the year 1929.

Dr. BEAN. Just the 1929 figure?

Dr. LUBIN. Yes.

Dr. BEAN. For all farms, 41 percent of the value of products, or gross income, went to the highest 10 percent in 1929, 32 percent in the case of cotton farms, 31.5 percent in the case of cash grain farms, 41.3 percent in the case of livestock farms—that livestock includes what the census called animal specialty, poultry, and stock ranches—48.3 percent in the case of fruit farms, and 42.8 percent in the case of crop specialty farms.

May I say that this proportion would probably be a little larger if it were put on a cash-income basis.

Dr. ANDERSON. Mr. Bean, I wish some of the other members of the staff would come up to the "mikes" so we could talk a little better.

PROSPECT OF GREAT TECHNOLOGICAL CHANGE

Dr. ANDERSON. Several questions occurred as we were going along, some of which were not cleared up during the morning session. There was one point raised just in passing, I think by Mr. Taylor, concerning impending technology on the farm. Your testimony this morning indicated major changes that have occurred and suggested that should one or another thing happen, there would be drastic results. You mentioned the Rust cotton picker. As experts in the field, have you come to any conclusion about impending technology which would drastically alter the material that we have been discussing today?

Do you anticipate any such drastic changes in the immediate or near future, and if so what do you think the trend would be?

Dr. JOHNSON. It is awfully difficult to anticipate something like that, and you have this kind of situation. A good many of these machines are on the horizon for a good many years before they are finally perfected, and also priced low enough in relation to the price of the product and of hand labor so that they will be widely adopted. I confess that I do not know at what stage the various kinds of pickers that are being experimented with will be adapted. We know that they are not ready for adoption today. How long it will be before they are generally adopted is a real question. For instance, the combine harvester was being experimented with, I think, as early as 1850, just quoting the date from memory, and, of course, it was used in the Pacific Northwest for a good many years before it got into the Great Plains country. Finally now in the last 4 or 5 years it is coming into wide use in the Corn Belt. If the cotton picker does become perfected so it can be widely adopted it will create a revolution in cotton which will be at least as important, perhaps much more important, than the revolution in wheat machinery—the combine and the associated tillage machinery in the small-grain areas.

Mr. PIKE. Just one question occurs to me. From what I have heard about the cotton pickers, my memory is that the trouble is not with the picker but with the cotton plant. I wonder what your idea would be in agriculture toward giving the country a cotton plant, if you thought you could.

Mr. JOHNSON. Well, I am not a plant breeder, but I do know that plant breeders are working on that at the present time. Of course, the unevenness of the ripening period varies in different sections of

the cotton South. You have much more uniform ripening periods and the cotton is left so that it can be picked much more at the same time in the western cotton area than in the Delta.

Mr. PIKE. Say, the Texas Panhandle area? They do use some mechanical means now and have for some years.

Mr. JOHNSON. Yes, but the Texas station especially is working with cotton plants more adapted to machine picking.

Dr. BEAN. The changes are slow. Perhaps it is easier for Mohammed to come to the mountain than it is for the plants to accommodate themselves to the picker.

Mr. PIKE. Well, you have done some very funny things with plants in the last several years.

Dr. BEAN. Or shall I say the time involved is too long?

Dr. LUBIN. That raises a very significant question, and I wonder whether we can get an opinion for the committee from this group, on the relative importance of machine technique and the other scientific information which has become available in the last generation. Now, Dr. Bean stated that the same number of people today are producing food for a much larger population than, say, 25 years ago, which means in turn an increased productivity of the farm population as a whole, of something between 50 and 70 percent.

Now, how much of that increased productivity is the result of better fertilizer, better breeding, the use of better seed, more efficient operation of farms, better use of land in the sense that it is selected and the more efficient acreage being used, and how much of it is attributable to machines as such?

In industry, several witnesses have stated that the big improvements of productivity have not come necessarily from machines in their particular cases, but from better organization, better knowledge of their products, and things of that sort.

One gets the impression, by looking at these figures that were submitted here today, that if you are going to explain that 50 to 70 percent increase in productivity, you must explain it in terms of scientific information, of the sort I mentioned, rather than in terms of the machine as such, although the machine must have played an awfully important part.

Now, is there any way of measuring the relative importance of the machine as opposed to these other things in measuring this increased productivity? Would it be 50-50 or 75-25 or what?

Dr. JOHNSON. I wouldn't have any quantitative basis for judging. I can give one illustration. Hybrid corn, for instance, has been tremendously important already because it has been widely adapted in the Corn Belt. Now, as it spreads out from the Corn Belt, it will, perhaps, be again as important in increasing the yield of corn as it has been today. So that you would have there an increase of about 200 bushels of corn as against an average corn crop of—speaking from memory—2,500,000,000 bushels.

Now, there is one significant increase in productivity of agriculture, coming from a scientific discovery. It is just an illustration.

Dr. LUBIN. Your land utilization problem would come into the picture there, wouldn't it? I mean, you select the better acreage?

Dr. JOHNSON. That has been done in recent years; yes. You have some increase in production per cow; you mentioned the question of commercial fertilizer. The sales of fertilizer are very closely asso-

ciated with the prices and income of the previous year in the fertilizer-using areas.

Dr. LUBIN. Have there been improvements in fertilizer?

Dr. JOHNSON. Oh, yes.

Dr. LUBIN. So that it is advantageous?

Dr. JOHNSON. Yes.

Dr. BEAN. May I supplement that comment? Insofar as fertilizer has been used chiefly in the South, you would expect to find some evidence of that increased use of fertilizer in terms of increased acreage, increased yield per acre in the South. My impression is that there has been no change in the level of acreage, or yield per acre, in the cotton South, up to recent years, say, the early 1930's. There has been a marked change in the level of yield per acre, in the average yield per acre, in the past 3 or 4 years, which apparently is associated with neither weather nor—I was going to say, with the fertilizer use, but I want to qualify that because I don't have those fertilizer figures per acre well enough in mind.

The fact that the change came rather abruptly in the years 1935 and 1937 would suggest that it may have been associated with the adjustment programs, where the emphasis, after 1935, was on improving yield per acre.

Mr. PIKE. Of course, in a great many cases, fertilizer is used more to check a decline—or as much to check a decline as it is to increase yield. I think that perhaps has been true in the South, that it became absolutely necessary to use fertilizer to get any reasonable return at all, and perhaps it dampened or checked the decline in that area that otherwise would definitely have occurred.

Dr. BEAN. I wonder, Dr. Lubin, if the answer to your question might not be put tentatively in this form, that insofar as you have an increase in productivity as the result of a reduction in the number of persons engaged in farming, that proportion of it may be associated with the increased use of machinery, and the excess or the balance of that increase of productivity might be associated with the scientific advances of hybrid seeds, more efficient use of feed, and the various other things?

Dr. LUBIN. In other words, the ratio would be about 4 to 1? In other words, 80 percent of the increased productivity of the agricultural plant country is attributable to science and the application of—

Dr. BEAN (interposing). No, I would put it more nearly 50-50, because you have had something like a 25 percent increase in productivity per person—no, you have had a reduction in the number of people engaged, which would account for what? About 20 percent increase in productivity?

Dr. LUBIN. No, in the past 25 years, you say there has been no change in the number of people who are feeding the country.

Dr. BEAN. But that is not exactly talking about workers in agriculture. I meant to check you on that earlier. The fact that we have 30,000,000 people on the land today and had 32,000,000 in 1910 doesn't mean that the same number of people are engaged in production; in fact, I am inclined to think that you have fewer people engaged in production, but the same number of people, the total number of persons, on the land.

Dr. LUBIN. Well, there has been a decline since 1915 of 1,300,000 people, which is approximately a 10-percent decline, in the total employment on the farm?

Dr. BEAN. Yes.

Dr. LUBIN. During that period of time, however, that 25 years, the population has increased by what? About 30 percent? So the ratio is 3 to 1. In other words, science has contributed 3 times as much to the increased efficiency as machinery.

Dr. BEAN. Well, you have come down from 8 to 1 to 3 to 1, and you might come down to 2 to 1.

Dr. LUBIN. So then it is 2 to 1? Is it 66-33?

Dr. BEAN. Well, I would like to—

Dr. ANDERSON (interposing). May I ask it in this way, Dr. Bean: aren't we dealing with things that are so vague and difficult to get at, that it is impossible, at this stage of our knowledge, to make even a rough estimate of the proportionate weights of these influences?

Dr. BEAN. That is why I would suggest that if the committee must have a figure, 50-50 is about as good a one as it can take. [Laughter.]

Dr. ANDERSON. I was going to put it a little bit differently, but isn't it possible to be much more precise by making your analysis in terms of particular crops for particular areas? In other words, just a moment ago you talked about the cotton in a certain area. This morning we saw some relationship to corn in a certain area. Isn't it possible, when you go into a specific crop and area, that you can get very much closer to the answer to Mr. Lubin's question?

Dr. BEAN. Yes; but you should not be too hopeful, because even on this question of hybrid corn, which has been talked about a great deal, there is no exact estimate as yet as to how much that scientific development has increased productivity. A figure of about 20 percent has been bandied about, but I happen to know the origin of that figure, so that I am inclined to say that we still don't know exactly what the truth is.

Dr. ANDERSON. Well, it would be true, would it not, that some areas in the country show a much higher rate of productivity, in volume of products and workers employed, than other areas?

Dr. BEAN. You mean a greater change in productivity?

Dr. ANDERSON. That is right.

Dr. BEAN. Yes.

Dr. ANDERSON. Are any scientific studies now in progress or recently completed which would attempt to measure these factors and their relative weights?

Dr. BEAN. I think, Dr. Johnson, that is yours.

Dr. JOHNSON. There are studies in progress that have not reached conclusion by any means, but the attempt is being made to measure it by commodities and by types of farms in the way that you have indicated.

Dr. ANDERSON. What is the purpose of making such a study? Why do we want to know precisely the weights of the relative influences?

Dr. JOHNSON. Well, I would say that that is the first requisite to understanding the situation. I think that it gives a much better background if we understand the forces that make up the total change.

Dr. BEAN. May I say something on that, too? Another reason for trying to discover the answer is to see whether we can anticipate the

number of people that will be required on the land to supply the food that the Nation is going to need over the next 5 or 10 years.

(Senator O'Mahoney resumed the chair.)

FUTURE MOVEMENT OF FARM POPULATION

Dr. ANDERSON. That leads to a question we have been asking almost every witness we have had before us, and we would like to put it here now. You indicated this morning a surplus labor supply on the farm available for migration, and you also indicated that, with conditions as they are in urban communities, this migration might not take place. Will that farm population, then, continue to grow; will there be more people on the farm in the immediate future, and possibly more unemployed on the farm also in the immediate future?

Dr. BEAN. Do you want to answer that, Mr. Taeuber?

Mr. TAEUBER. I see no escape from that conclusion, if there is no resumption of the migration sufficient to offset the excess of births over deaths on farms, which is now between 300,000 and 400,000 per year.

Dr. ANDERSON. So that the farm, in your opinion, does not offer the opportunity to these unemployed city workers that it did in the past?

Mr. TAEUBER. No.

Dr. ANDERSON. Well, in that connection, what happens to the whole program of so-called public subsistence farming, the maintaining of people on the land even though they are not able to compete on commercial terms?

Dr. BEAN. You mean what is the significance of it?

Dr. ANDERSON. That is right, and its future.

Dr. BEAN. Well, in my mind, if we have a subsistence farming program, we would be altering our notions as to the kind of life that certain groups in the country should lead.

The CHAIRMAN. It would be a complete alteration of the American idea of what constitutes society, wouldn't it?

Dr. BEAN. Yes. So far we have accepted the notion that if you can't make a living on the land you move into town and try your hand there. A subsistence kind of existence would mean that, since you can't find a place in the cities and since by remaining on the land you are just producing more and lowering the general standard of living for those commercially engaged, you'd better find yourself another kind of life which would be neither commercial farming nor industrial activity. What that intermediate is is something that we will probably have to do some tall thinking about.

Representative WILLIAMS. After all, that might be better than to be in the congested cities and in the slums without anything to do, and dependent entirely upon charity relief.

Dr. BEAN. There is a great deal behind that word "better," and it is there where you begin to deal with different notions of standard of living.

Representative WILLIAMS. I have been interested in one thing I wanted to ask, and that is, the effect that our agricultural adjustment program has had on production. It seems that from 1934 to 1937 this production rose from a percentage of 82 in 1934 to 104, according to the plat I have here in front of me. During that same period there was considerable acreage taken out of cultivation, wasn't there?

Dr. BEAN. I think you can bring those two together by studying not only the index of production but the size of the farm enterprise.

Representative WILLIAMS. That is the fact, though, is it—the production was very much greater in 1937 than it was in 1934?

Dr. BEAN. Well, you have there the extreme difference between a drought of 1934 and the most abundant year of 1937.

Representative WILLIAMS. All right; you take 1937 and it is above all time.

Dr. BEAN. Yes; you have record production of cotton and substantial production of grains.

Representative WILLIAMS. And in 1938 it had come down; 1938 is the last one shown there, but it is still far above the average. That has taken place notwithstanding the fact, as I understood this program, that it was to at least try to adjust production to consumption and maintain a higher standard for the farmers of the country, and to that end the Government itself has spent many, many million dollars. It doesn't seem to be working, and that is what I would like to know; if we are not doing any good along that line, I feel like we ought to quit the program, maybe.

Mr. HOLCOMB. I believe in 1937 the volunteer program was on, and quite a few of them did overplant in cotton acreage.

Dr. BEAN. The Secretary of Agriculture commented with respect to the production changes after 1936, that prior to the Supreme Court decision, the programs were more exact, more specific, in that they dealt with specific crops. After that decision the agricultural programs became general. They became soil-conservation programs, where you didn't have exact control of acreage, because you were dealing with a general program instead of commodity programs. The combination of an expansion in acreage under that system, and good weather, produced, say, the bumper crop of 1937, part of which we still have on hand.

Representative WILLIAMS. The fact is, isn't it, that there has been a very substantial reduction in acreage? Is that a fact or not?

Mr. HOLCOMB. Of certain crops.

Dr. BEAN. That is indicated in this measure labeled "Site of the farm enterprise," which is really nothing more than the aggregate acreage harvested.

Dr. JOHNSON. Plus numbers of livestock.

Dr. BEAN. Which went down from an index of 102 or 103 in 1931 or 1932, to about 93 in 1938, so that you had approximately a 10-percent reduction in aggregate acreage and livestock.

Representative WILLIAMS. That was the very deliberate purpose of the program, wasn't it?

Dr. BEAN. Yes. There was an attempt to reduce production for export.

Representative WILLIAMS. In order to adjust production to domestic consumption and, therefore, give the farmers a better price. Now, that was the very fundamental of the program, as I understood it. Is that correct?

Dr. BEAN. Yes; farmers have better prices, have higher incomes, but I am not sure that this is where you want a dissertation in defense of A. A. A. programs.

Representative WILLIAMS. I was just wondering and asking you men who have made a study of it what effect it has had on production

and prices. It is sometimes claimed by some who are not in favor of the program that it has been disastrous to the farmers, and not effective. I have not been one of those, but I was wondering how the men who have made a particular study of the situation think of it.

Dr. BEAN. In general, I find myself in your company on that question.

Representative WILLIAMS. But on the other hand, it does seem that there has been a very substantial increase of production there, and the piling up of an inordinate surplus in some products, especially cotton.

Dr. BEAN. There is no denying that acreage control by itself doesn't effectively control production, where you have variations in the weather to contend with, and for that reason Congress has written into the law certain controls of marketing as well as control of acreage, to deal with the weather factor as well as with acreage.

The CHAIRMAN. I like this euphemism, "Congress has written into the law." We pass the law that you fellows write.

Dr. JOHNSON. You flatter us.

The CHAIRMAN. I was very much interested in some of the charts that were presented here earlier in the afternoon, which illustrate the fact which is well known to all students of the agricultural problem, that the percentage of farm ownership is steadily decreasing in the United States, the number of farmer-owner operators has been steadily decreasing year by year for more than 50 years. That is a fact, isn't it?

Mr. WALL. That is true.

INCREASE OF CORPORATE FARM OWNERSHIP

The CHAIRMAN. Corporate farming, institutional farming, has been increasing during this time; isn't that true?

Mr. WALL. Particularly during the last decade.

The CHAIRMAN. Exactly.

Dr. JOHNSON. Corporate ownership, wouldn't you say, more than corporate farming?

Mr. WALL. Corporate ownership.

The CHAIRMAN. Tenant farming has been increasing and corporate ownership has been increasing, but all of these farm programs are based not upon any concept of the effect upon the operator or the tenant as an individual, but in terms of production. Am I right?

Dr. BEAN. I think that statement would cover pretty well the agricultural adjustment philosophy of 1933, where the problem was prices, volume, and income for the Nation as a whole, the creation of a new flow of purchasing power.

The CHAIRMAN. Isn't that a correct statement of the present philosophy? Soil conservation is carried on and the payments are made regardless of the type of ownership.

Dr. BEAN. Well, I think you have additional things that have been created since 1933. The farm-security program, I think, is not quite the way you describe it.

The CHAIRMAN. No; of course, the farm-security program, I think, is separate and distinct policy, and that has to do with an attempt to preserve families upon the land; that is true.

Dr. BEAN. You have the tenant program in the same category. True, it is very small, but at least the philosophy has been developed, and here and there accepted.

The CHAIRMAN. Yes; but neither of those is geared to production, and soil conservation is geared to production.

Dr. BEAN. That's right.

The CHAIRMAN. That's correct, isn't it?

Dr. BEAN. Yes.

The CHAIRMAN. So that in whatever benefits or subsidies we extend to the farmer, we make no differentiation between the corporate farmer and the flesh-and-blood farmer. Is that right?

Dr. BEAN. That is right.

Dr. JOHNSON. We limit the size of the benefits.

Representative WILLIAMS. We limit the size of the benefits we pay to them.

The CHAIRMAN. That is one concession that has been granted to them.

Dr. BEAN. That may also affect the noncorporate farmer of large size as well.

Mr. PIKE. How does this control tie in—well, I just went back to the country last year and found a barn half full of superphosphates that the Government had given me to improve what was left of the acreage, so that I could raise, perhaps, as much on, I should think, about one-third of the acreage as I did on the whole of it before. I couldn't tie that in, lying for 2 or 3 years. It would make good farmers cramp themselves, I am afraid, by holding down, taking out of production here, and then all this refertilization. I couldn't rationalize it. We had to take it and put it on the land. It was sort of contradictory.

Dr. BEAN. In general, I would say that the philosophy probably is that if we are going to produce, we might as well produce as efficiently whatever the country requires, and if you are going to produce a certain amount of bales of cotton, say 12,000,000 or 13,000,000 bales, you want to produce it as efficiently as possible.

Mr. PIKE. That still isn't quite clear.

Dr. BEAN. Also, if you want to produce 5,000,000 automobiles, you produce those as efficiently as possible in terms of manpower and other costs. That is what I take it is society's frame of mind at the present time.

The CHAIRMAN. Have you, in these discussions, indicated the trend of agricultural development in relation to employment?

Dr. ANDERSON. Yes.

The CHAIRMAN. You have. And what is that trend?

Dr. BEAN. In general, it is that over the years we can expect to produce either more agricultural products with the same number of people that are now on the land, or the same volume of production with fewer people on the land, and unless there is an opening up of an entirely new channel of consumption, it would be difficult to see any opportunities on the land for people who are not now there. In fact, there is difficulty to see opportunities for all the people that are now living on the land.

The CHAIRMAN. Well, what opportunities do you see for new uses of agricultural products?

Dr. BEAN. There are a thousand and one uses of agricultural products, new uses, that are being experimented with but, for some reason or other, these uses just don't occur rapidly enough for the immediate situation within the next 2 or 3 or 4 years.

Dr. JOHNSON. For the future, but not for the immediate time.

Dr. BEAN. We have an exhibit in the Department of Agriculture now of the many uses of cotton that have been developed—gears and handles and what-not, all sorts of things it is difficult to imagine that you can use cotton for, but in the aggregate those things at present don't consume a great deal of cotton. They may in time, but that is in the lap of genius of the scientists.

The CHAIRMAN. What can be done to stimulate the development of new uses?

Dr. BEAN. The Department of Agriculture, I believe, has quite an extensive program of effort in that direction.

The CHAIRMAN. The opportunity is there, is it not, and it is recognized.

Dr. BEAN. I would say the hope is there. Whether opportunity is, I don't know. For example, a good deal—

The CHAIRMAN (interposing). I didn't mean opportunity in the commercialized sense. You speak of all these possible uses of cotton but for some reason or another they don't develop. Is that because they have not been made commercially profitable as yet?

Dr. BEAN. That is probably a factor.

The CHAIRMAN. Is it true, for example, that the use of alcohol as a fuel has long been recognized but it cannot yet be produced at a price to make it competitive with oil or gasoline? Is that correct?

Dr. BEAN. Yes, sir.

The CHAIRMAN. So science, chemistry, already can point out to us innumerable new uses for agricultural products which are not being taken advantage of because they are not yet in a competitive stage.

Dr. BEAN. Yes; but that same science needs to make one more remark, namely, that we scientists need to discover how to use agricultural products in these new ways on a commercial basis, but it isn't up to the farmer or to any of us who are not scientists to develop the new uses, after scientists merely tell us that here is a place; it is still the scientists' job to discover the next trick, which is to bring that process down onto a commercial level.

The CHAIRMAN. Well, could we bring it to a commercial level by using the same device that we used to bring so-called infant industries to a commercial level?

Dr. BEAN. I am not sure I have in mind—

The CHAIRMAN. Tariff as an exclusion policy, an isolation policy.

Dr. BEAN. That is a question of many, many colors.

The CHAIRMAN. It presents itself to any student of this problem because the alternative seems to be the subsistence homestead and the reduction of a large proportion of our people to a peasant class.

Dr. BEAN. Not necessarily.

The CHAIRMAN. What is the alternative if that isn't it? We have the Farm Security Administration, which is an effort to keep farm families on the land, whereas we know that your testimony here is absolutely correct, namely, that production per man is increasing, and the market is not increasing.

Dr. BEAN. If you will allow me to make a statement without spelling it out in detail, because I don't have the detail, I would say this: We ought to be able to look forward to opportunities of employment which are not in the industrial centers and not in commercial agriculture, but somewhere in between where we utilize our resources more effectively than we now do. Some people call that a rural works program, or some kind of a set of opportunities for work which doesn't necessarily have to be a subsistence type of living.

EFFECT OF INCREASED EMPLOYMENT ON FARM PRODUCTION

Dr. LUBIN. Mr. Bean, let's assume the per capita consumption of all goods in America were equal today to what they were in 1929, which means in turn, let's say, that we would be employing in industry and in service trades and transportation, just for the sake of argument—I don't know what the figures would be—6,000,000 or 7,000,000 more people than we are employing in those forms of activity today. What would that mean in terms of consumption of farm products? Or put it this way, wouldn't an increase in employment by 7,000,000 or 8,000,000 in other types of economic activities so increase the demand for farm products that this problem you are talking about would disappear?

Dr. BEAN. It all depends on how much time you are going to take to get that increase in employment. If you can do it immediately, overnight, then, of course, you have a stepping-up of agricultural consumption. The extent of that stepping-up will depend on the extent to which consumption by the unemployed is now below standard, and it probably isn't as much below standard as the overall impression would suggest. It would still leave us, incidentally, with an unemployment problem on the land, because when you merely absorb 6,000,000 people in your industry, you are not even doing a good job of employing the number that are variously estimated to be unemployed in the cities. In the testimony this morning, you had various figures which, while the figures were of wide range, nevertheless indicated a substantial unemployment problem in the rural and farm areas, somewhere perhaps around 2,000,000 people.

The CHAIRMAN. Are you indicating to us that if all of the unemployed were capable of purchasing food and agricultural commodities as though they were receiving \$1,200 a year, there would still not be an appreciable increase of the market for agricultural products?

Dr. BEAN. Yes; I think there would be an increase, but I think it would be an increase which the farmers on the land now can supply and still leave us with a block of people on the land who ought to be working more effectively in other pursuits.

The CHAIRMAN. On what do you base that conclusion? Is that an impression that you get from your readings and your studies, or is it a well-developed conclusion? I ask you that question because the Surplus Commodities Corporation seems to feel that there would be a very substantial increase of consumption.

Dr. BEAN. Provided you channelize that increased purchasing power into food or farm products. Do I make myself clear? The Surplus Commodities Corporation adds purchasing power to the family with the proviso that that increased purchasing power be spent for food.

Whether or not you would get the same increase, the same use of purchasing power, if it were created without any strings tied to it, I don't know. The fact that so-called size of farm income, the average of acreage harvested in the past few years, has been roughly 10 percent less than in 1930, with from 8,000,000 to 10,000,000 people employed in agriculture today as against 11,300,000 in 1929—which suggests to me that there are additional people around there somewhere that are not working—all that suggests to me that the people now on the land can produce more than we are now producing to supply this increased consumption that you might expect from an increase in purchasing power.

The CHAIRMAN. Of course, what is true of our economy, of our agricultural economy, is necessarily true of every other agricultural economy, too, in varying degrees. The capacity of the land to produce is not altered by the flag that flies over the land, is it?

Dr. BEAN. Well, if you have in mind such technological advances as we make, they are easily and quickly transferred to other countries, in expansion of agricultural output, just as in the United States.

The CHAIRMAN. So that leads us to the question whether we should be content to see our future in the marketing of surpluses in other countries which eventually, if not immediately, will be producing their own surpluses.

Dr. BEAN. That, of course, opens up the area where statesmanship has its task for the next few years, dealing with the international flow of surplus raw materials.

Dr. ANDERSON. Dr. Bean, the National Resources Committee's study of consumer expenditures indicates that it would take an expenditure of about \$2,000,000,000 for food to move the lowest third up to the level of the middle third. Would that size expenditure, in your opinion, alter the employment situation in agriculture?

Mr. BEAN. You assume that an increase in expenditures for food must be effected in the form of an increase in the volume of intake, which I think isn't a necessary assumption.

Dr. ANDERSON. It would take an additional expenditure of \$2,000,000,000 on food to move these people into the level of consumption expenditure with the middle third of the Nation.

Dr. BEAN. I say that that increase in expenditures doesn't necessarily mean a comparable increase in volume.

Dr. ANDERSON. That is quite likely.

Dr. BEAN. We have the whole question of change of diet and quality.

Mr. WALL. If we were to increase consumer income by the proportions that you have indicated, the increase in farm income would give rise to additional employment in the service occupations and in perhaps farm construction, because with a higher level of farm income you would open up, I think, a certain amount of additional employment in agricultural areas, in rural areas.

Dr. ANDERSON. In the over-all.

Mr. WALL. In the over-all.

Dr. BEAN. That is right. Let's see if we can get a little closer to the implication of that figure. You have \$1,900,000,000 increase in consumer expenditures. Farmers would get roughly half of that, close to \$1,000,000,000. Then the question is, will consumers buy 10 percent more in volume, or will they merely be changing their type of intake without increasing their volume, merely paying for another

set of services? If half of that increase in purchasing power means increased volume, that would mean what, roughly, a 10-percent increase in the aggregate volume of farm products?

Dr. ANDERSON. Possibly.

Dr. BEAN. But you have the underlying fact that over the years the aggregate volume of consumption of farm products doesn't vary with the rise and fall of the national income, and this computation is based partly on that concept, so that it is difficult to conclude that that much increase in income would actually give you that much more employment in agriculture for additional production.

Dr. ANDERSON. There is one other problem that has bothered me all day long during the discussion. Having something of a farm background, I have been led to regard farming and independent ownership as somehow linked with the concept of Americanism, that as landed people we have the right to own a farm and operate it. In your discussion this morning you showed that apparently the rungs are being taken out of the agricultural ladder and we can't move so readily from the bottom to the top. Is that a continuing trend which will foredoom an increasingly large number of people to tenancy, and keep them from ever becoming independent owners on the farm?

Mr. HOLCOMB. I don't know about the doom, but I think that there is reason to believe it will become increasingly difficult to rise from the lower rungs of the ladder to the higher ones, as we increase the amount of capital necessary to become owners or tenants. If the machinery is made available to them at lower and lower prices, that may facilitate the rise in the ladder. However, the increased productivity of individuals may tend to shunt out an increasing number of workers in the field.

The CHAIRMAN. Have any of these farm experts testified as to any relationship between the machine and the amount of food consumed by the individual who uses the machine? In other words, did a hand worker in the old days eat more than a machine worker today?

Dr. BEAN. Have we had that kind of testimony for the rest of the economy?

The CHAIRMAN. No.

Dr. BEAN. None was brought here this morning.

I have a feeling that that is a real question.

The CHAIRMAN. I would naturally assume that a person who worked with his hands laboriously would consume a great deal more food than one who didn't work so laboriously. I would assume, for example, that an outdoor worker, a laborer, would eat more than an office worker because of the increased demand upon the body for effort, and naturally an increased consumption of body forces. I wondered if the statisticians and philosophers of the Department of Agriculture had ever studied that possibility.

Dr. BEAN. Like yourself we have thought about it and have come to about the same conclusion, that it must be so.

Mr. LUBIN. I think in many types of industrial activity the amount of energy a man uses is much greater, concentrated for a shorter period of time, of course, than work by hand; I should assume that running a caterpillar tractor 8 hours a day probably takes more energy out of you than if you were digging a hole.

The CHAIRMAN. Undoubtedly that would be true in many instances, but I think it is also probably true that the use of the machine by and large has reduced the amount of physical effort which all workers must exert.

Dr. BEAN. I think that a complementary question to yours has to do with the increase in the service industry, and that probably is related to the reduction in the per capita consumption of such things as wheat.

The CHAIRMAN. Of course we do know that there has been a very marked change in the diet, the change from meat to salads has been marked. Some of your experts in domestic economy have testified from time to time with respect to that.

Dr. BEAN. We have had a net reduction in the per capita consumption of pork and cereals in the past generation.

The CHAIRMAN. And it seems to me that I have a very distinct recollection of an intensive drive that was made several years ago against some of the publications of the Department of Agriculture, because it was alleged that they were tending to impair the consumption of wheat and flour.

Well, are there any other questions? If not, what is your program?

(Off-the-record statement by Dr. Anderson.)

The CHAIRMAN. Then we will stand adjourned until 10:30 o'clock tomorrow morning, in room 357.

(Whereupon, at 5:20 o'clock, a recess was taken until Wednesday, April 24, 1940, at 10:30 a. m.)

INVESTIGATION OF CONCENTRATION OF ECONOMIC POWER

WEDNESDAY, APRIL 24, 1940

UNITED STATES SENATE,
TEMPORARY NATIONAL ECONOMIC COMMITTEE,
Washington, D. C.

The committee met at 10:40 a. m., pursuant to adjournment on Tuesday, April 23, 1940, in room 357, Senate Office Building, the chairman, Senator Joseph C. O'Mahoney, presiding.

Present: Senators O'Mahoney (chairman), and King; Representative Sumners (vice chairman); Messrs. Kades, Lubin, O'Connell, Pike, Kreps, and Brackett.

Present also: S. Abbot Maginnis, Department of Justice, William T. Chantland, Federal Trade Commission, and Dewey Anderson, economic consultant to the committee.

(The committee meeting was preceded by the showing of moving picture films of mechanization in farming operations.)

The CHAIRMAN. The committee will please come to order. Your first witness this morning.

Dr. ANDERSON. The first witness this morning is Mr. Fowler McCormick, vice president of the International Harvester Co., of Chicago, Ill. Mr. McCormick has prepared a statement which he wants to read and offer certain exhibits.

The CHAIRMAN. If Mr. McCormick will come forward, we will begin.

Do you solemnly swear that the testimony you are about to give in this proceeding shall be the truth, the whole truth, and nothing but the truth, so help you God?

Mr. McCORMICK. I do.

TESTIMONY OF FOWLER McCORMICK, VICE PRESIDENT, INTERNATIONAL HARVESTER CO., CHICAGO, ILL.

The CHAIRMAN. Won't you please give your name to the reporter, for the record.

Mr. McCORMICK. My name is Fowler McCormick.

The CHAIRMAN. And your position.

Mr. McCORMICK. I am vice president of the International Harvester Co.

The CHAIRMAN. How long have you occupied that position?

Mr. McCORMICK. I have been vice president since 1934.

The CHAIRMAN. And are you not a descendant of the original McCormick who was the inventor of the first harvester?

Mr. McCORMICK. I am a grandson, Senator.

The CHAIRMAN. You are his grandson?

Mr. McCORMICK. Yes, sir.

The CHAIRMAN. Are there any other questions that you wanted to ask?

Dr. ANDERSON. Mr. McCormick, how long have you been engaged in the business of farm implements?

Mr. McCORMICK. Well, I have been in the business for 41 years, in a sense, in another sense, 15.

Dr. ANDERSON. In other words, you grew up in the business.

Mr. McCORMICK. Just about.

Dr. ANDERSON. And you observed its effect and growth and development.

Mr. McCORMICK. For a considerable period I have been directly connected with it; yes.

The CHAIRMAN. Mr. McCormick, the committee is indebted to you and to your associates for the presentation of the motion picture which we have just seen exhibited in another room in this building. It certainly leaves no doubt that farming is much less a back-breaking job in 1940 than at any other time in the long history of upward progress of the human race. There can be no question about that. I suppose, however, that there still remains unanswered the problem of markets for increased production. All the testimony which we have had presented to us to date in this committee, from every angle, whether from the point of view of the manufacture of machines or from the point of view of the representatives of labor, has been to the effect that by reason of technological advance we are now having much greater production per man than ever before. The machine is unquestionably a labor-saving device, and there is some testimony to the effect, a good deal of testimony, I may say, that it is also a job-displacing device, and, of course, it is obvious that the use of machines and the purchase of the product of the machines depends upon the ability of people to buy the machine and to buy the product, so finally we come down to the question of how we are going to promote markets for the products of the farm and of the factory.

Mr. McCORMICK. That is very true.

The CHAIRMAN. You may proceed.

The VICE CHAIRMAN. Mr. Chairman, just before Mr. McCormick proceeds, may I make a little observation, a very short one?

The CHAIRMAN. We will be very, very happy to have you do so. Your observations are always interesting and constructive.

The VICE CHAIRMAN. This observation I suggest for the consideration of the country as a whole in connection with this record. It was stated in connection with this magnificent exhibition to this effect. The question was asked, "Where are the people who could or would do the work now done by machine?"

That query would indicate a great progress in the strength and efficiency of the machine, probably a corresponding deterioration in the strength and courage and determination and capacity of the human being. I don't make that observation in any criticism of what we call progress, but it seems to me that society should give some consideration in connection with its progress as to whether or not it is developing, whether or not it is making strong machines and weak people, whether or not the capacity to do things and the responsibility of doing things is being shifted from people to machines.

One of the interesting observations that was made in connection with this exhibition—and I want to repeat that certainly what I am saying is no criticism of anything that is being done—was that it wasn't any strain on the fellow's suspenders to operate those machines. There is not much strain on his muscles, and muscles grow stronger with us. There is not awfully much strain on his head. It doesn't tend to strengthen the thinking machine. Of course, it is a little more difficult to operate a complex machine, but, after all, there was a good deal of individual resourcefulness required when a fellow was plowing on a hillside with a bull-tongue plow in the days of long ago.

Something was said about putting hay up on the wagon by the Armstrong method. It musn't be forgotten that when you changed from putting it up on the wagon by the Armstrong method, the tendency was for the arms to cease to be strong, because nature is not disposed to let strength remain where it is not used.

Now, I hope I make myself clear. I am not at all criticizing. I do have a good deal of the fogie in me; I admit that, but I am reasonable. I am not criticizing this progress. I know that machinery has done a great thing in progress. But in connection with this appreciation of what machinery is doing, it seems to me, as indicated by our chairman, we are going to probably have to be cautious that we don't develop a sort of warfare between machinery and human beings. He has indicated that. That is one of the big problems that you are not here to talk about, but I think you will probably have to think about it. When I was looking at the work that was being done by the magnificent machine, I was thinking of the picture I see when I go home, of these tenant farmers sitting around on the streets, living off direct or indirect contributions from other people. It presents a serious question.

I want to continue to repeat, because I don't want to be misunderstood about it, I am not saying this in any criticism of what you gentlemen have done who are making this wonderful progress, but I think society is well able to realize it charges them with some additional responsibility, and we have to meet that.

That is the line of talk that I thought might impress my people. I have got to come up for reelection pretty soon.

The CHAIRMAN. Well, the vice chairman's talk to his constituents prompts the chairman to add a few remarks to what has already been said in this record. I think there can be no doubt that the machinery has done a great deal to improve the living standards of the human race. No one, I think, would have the hardihood to deny that. The trouble, as I see it, is that it hasn't done enough. Our problem is to find a way by which it can do the remaining job, which is, of course, to provide full employment for all who want and need jobs. The machine has certainly been very successful in contributing to the creation of abundance, abundance of farm products and abundance of all types of natural resources, abundance of all types of commodities that the human race needs or desires. There can be no doubt that the machine has also created a great deal of leisure. We saw the leisure in the farm home on the picture that you presented this morning, Mr. McCormick. The long, long day of the farmer has been made unnecessary by farm machinery, and the long day in the shop has been made unnecessary. There is no question about that.

The machine has created leisure. The trouble is that it has also created a certain amount of unpaid leisure. That is the forced leisure of the workman who, though he wants a job, can't find a job, and because he can't find a job, if he is a farmer or a farm tenant he can't get the land upon which to buy the tractors that the International Harvester and Allis Chalmers and the others make.

I'm sorry.

Dr. ANDERSON. May we proceed?

The CHAIRMAN. That was also a speech to my constituents. [Laughter.]

Senator KING. May I make an observation, but not in the way of explanation? I am listening, and after the testimony is all in, than I may submit a statement for the record.

Dr. ANDERSON. Very good.

Mr. McCORMICK. Mr. Chairman, if I might defer any comment on the Congressman's remark, I think they are very pertinent indeed, and perhaps we can go into them more fully a little bit later. I want to express at the beginning our appreciation of the time that you gentlemen have taken to see those pictures given by Allis Chalmers, the Deere Co., and ourselves. We had a feeling that they might be illustrative of some of the modern practices in the industry, and we very much appreciate the time you have taken.

Mr. Chairman, if I may ask your permission, we have prepared a statement on behalf of our company which I will ask your permission to insert in the record because there are two exhibits in the back of the statement, and than I should like to read the greater proportion of the statement, if I may.

The CHAIRMAN. To avoid duplication, this statement now presented will appear in the record as the statement which you are making.

Mr. McCORMICK. If that is permissible.

The CHAIRMAN. Without objection that will be the rule.

(The charts referred to were marked "Exhibits Nos. 2681 and 2682" and appear facing p. 17604 and on p. 17005.)

Mr. McCORMICK. I am glad to come here to give any assistance I can to your study of the progress of technology. No such inquiry, naturally, could be complete without a careful examination of the technology of farming, for the farm is the basis of our civilization. If there had been no developing farm technology, there could be no industrial America as we know it today.

That is true, I believe, because the farm has furnished two of the absolute essentials of an industrial society—adequate food and available manpower. Today we take those things for granted. This could not have come about unless farm technology had removed the fear of famine and set men free to work in industry, at manufacturing, selling, and transporting goods of all kinds.

In addition to these general benefits, the progress of farm mechanization has made the farmer's life more attractive and enabled him to raise his income by reducing his costs of production.

There are many questions touching on farming which I am not competent to discuss. I do not come before you today as an agricultural economist or a sociologist. I am able to suggest no panacea for unemployment, on or off the farm. I think it is obvious that advancing technology, whether in farms or in industrial regions,

PRICE COMPARISONS FARM MACHINES AND OTHER PRODUCTS

This chart shows how the 1937 wholesale prices of typical farm machines and other manufactured products used by farmers compare with the pre-war (1913) prices of these same products. The chart also compares 1913 and 1937 prices of materials and 1936 wage rates (1937 rates not available). The figure before each item shows the percentage which the 1937 price is of the 1913 price.

HOW TO READ THIS CHART

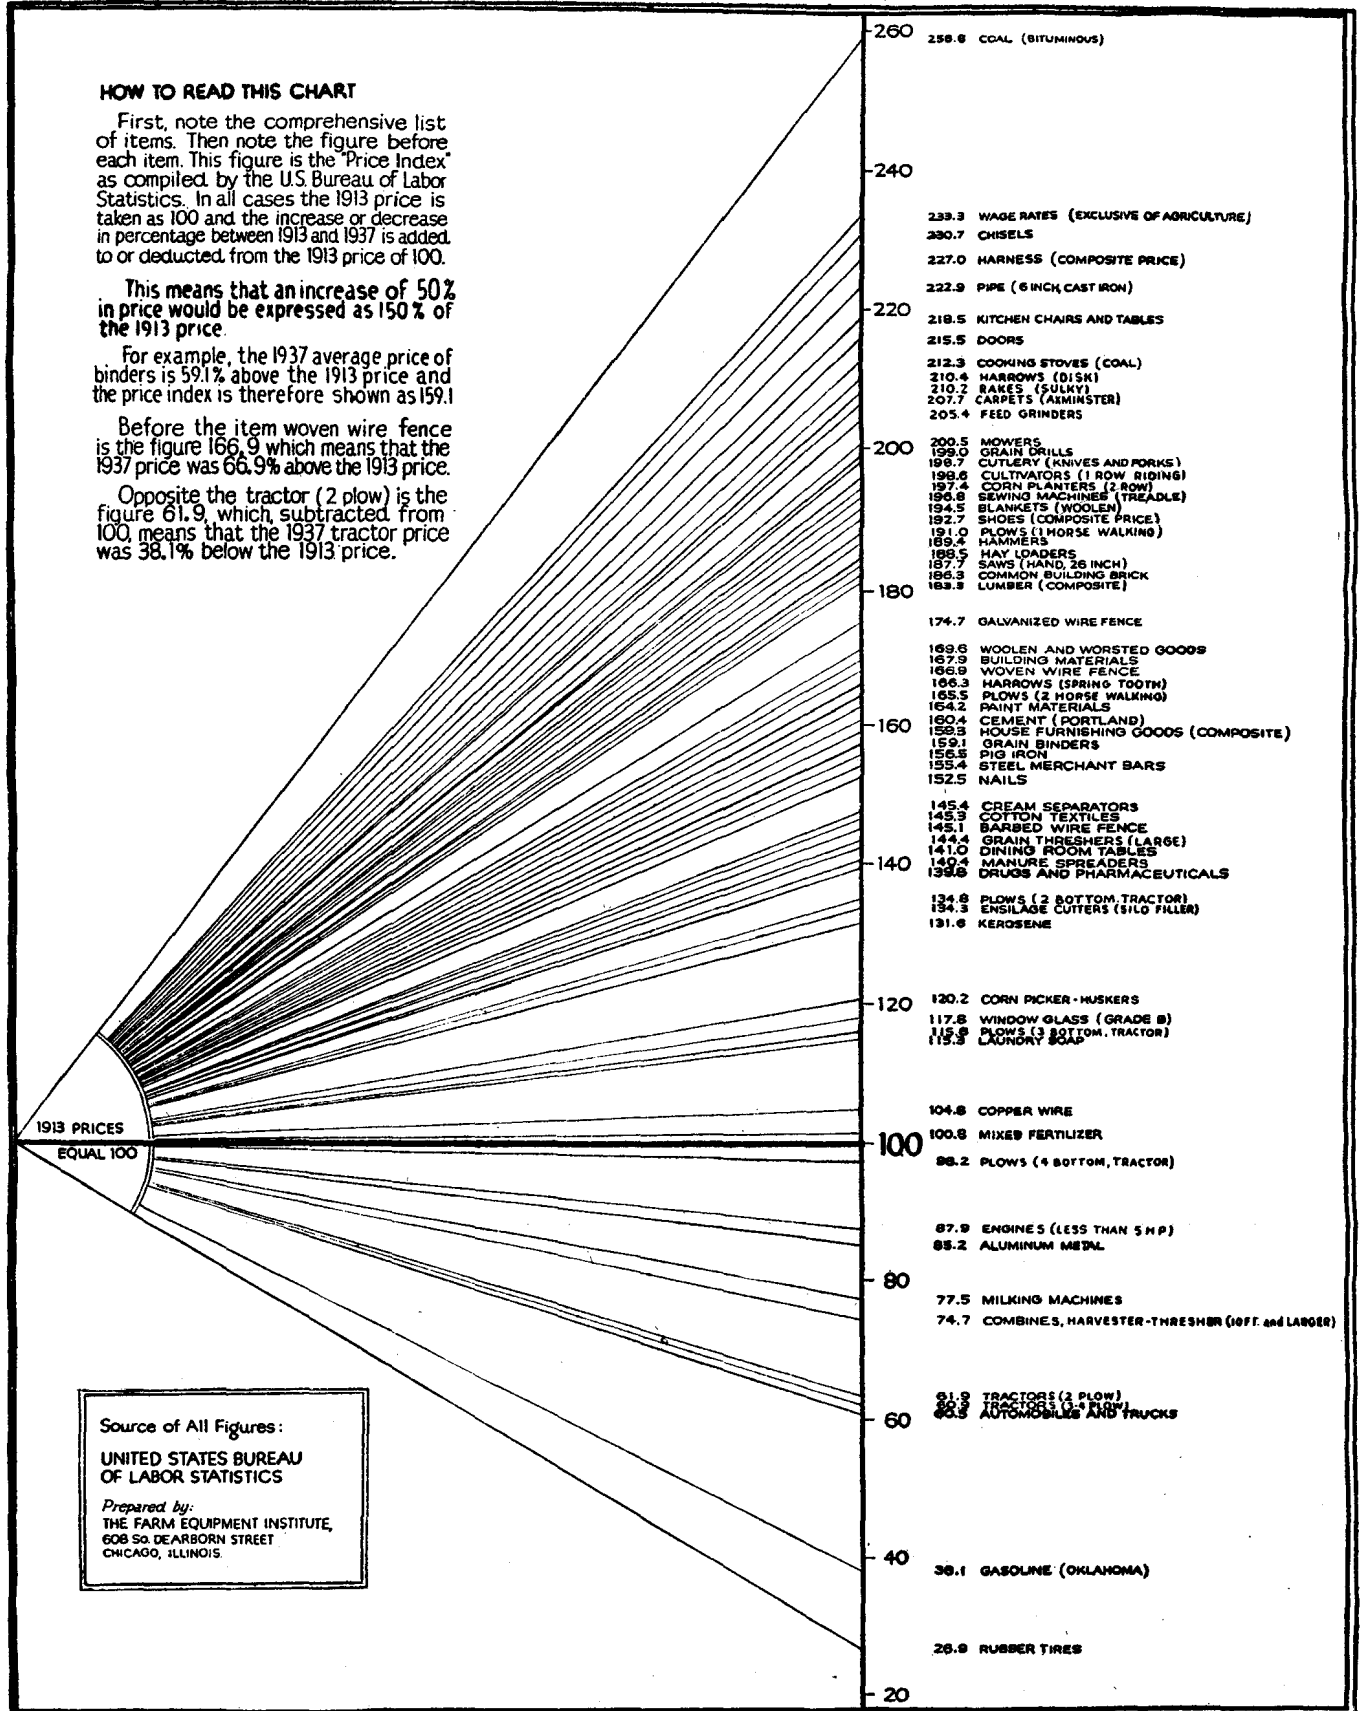

First, note the comprehensive list of items. Then note the figure before each item. This figure is the "Price Index" as compiled by the U.S. Bureau of Labor Statistics. In all cases the 1913 price is taken as 100 and the increase or decrease in percentage between 1913 and 1937 is added to or deducted from the 1913 price of 100.

This means that an increase of 50% in price would be expressed as 150% of the 1913 price.

For example, the 1937 average price of binders is 59.1% above the 1913 price and the price index is therefore shown as 159.1.

Before the item woven wire fence is the figure 166.9 which means that the 1937 price was 66.9% above the 1913 price.

Opposite the tractor (2 plow) is the figure 61.9, which, subtracted from 100, means that the 1937 tractor price was 38.1% below the 1913 price.

EXHIBIT No. 2682

THE FARM DOLLAR DISTRIBUTION OF U.S. FARMER'S 1931 EXPENSES

YEAR	GROSS FARM INCOME (1)	EXPENDITURES FOR FARM IMPLEMENTS, TRACTORS AND REPAIRS (1)	% OF FARM MACHINERY EXPENDITURES TO GROSS FARM INCOME
1932	\$ 5,562	\$ 95	1.7 %
1933	6,404	96	1.5
1934	7,629	194	2.5
1935	8,688	343	3.9
1936	9,672	464	4.8
1937	10,425	585	5.6
1938	9,290	475	5.1
1939	9,100	422	4.9

(1) IN MILLIONS OF DOLLARS

sometimes results in displacements of labor. Although the distress caused in this way is generally temporary and local, it is nevertheless acute to those affected and is important to society in general. Obviously, solutions of these problems are of vital importance.

MECHANIZATION IN AGRICULTURE

Mr. McCORMICK. I think I must limit myself to the contributions to farm technology which have been made by the industry with which I am connected, and I say that in the sense, Mr. Chairman, that I think technology can rightly include other fields in which we are

not expert or engaged, such as the improvement of seed, improvement of plants and fertilizers and farm buildings, and so forth, and I don't intend to touch on them today.

These contributions of our industry lie chiefly in two areas—the mechanization of farm production methods and the development of farm transportation through the use of the motor truck.

The problem of the farmer under any economic system is to produce as efficiently, as unfailingly, and as easily as possible. The business of our industry is to improve the farmer's ability to do that. I want to talk a little, if I may, about what machines have achieved, what they have failed to achieve, what the sources of farm mechanization are, what some of the present tendencies and future possibilities are, and what some of the results and contributions have been as I see them.

Most of you are generally familiar, I believe, with the evolution of farm machinery. But since my later remarks will be based on the course which that evolution has followed, it might be well to review briefly some of the high spots in the history of farm mechanization.

Prior to 1831 agriculture had been for many centuries an industry which utilized human labor as its source of power. Animal power had been brought into the picture only partially. The most notable uses of animal power were in plowing with wooden or cast-iron plows, and in hauling. The other processes, planting, cultivation, harvesting, were carried on almost entirely by hand.

The two decades between 1830 and 1850 witnessed a remarkable revolution in agricultural methods. The reaper was invented in 1831. The machine that was to become the basic mower appeared 3 years later. The steel plow, which made it possible to plow the rich, sticky soil of the prairies was invented in 1837. The threshing machine came in 1834; the earliest combine in 1836. Grain drills, permitting more accurate planting of seed than was possible with hand sowing, appeared in the forties.

The effect of these inventions was almost immediately apparent. The time required to harvest an acre of wheat, for instance, was reduced approximately 65 percent between 1830 and 1840, from an estimated 37 hours in 1830 to an estimated 11½ hours in 1840.

These new machines all utilized animal power, usually in the form of horses or mules.

The next half century between 1850 and 1900 witnessed the development of many other machines, including the corn planter, improved types of harrows and cultivators, the grain binder which was evolved from the reaper, and, on the Pacific coast, the big combine powered by from 18 to 50 horses.

Throughout the period, farm machinery underwent a continuing process of improvement in design, production methods, materials, and utility, and new machines and accessories continued to be developed for special purposes according to the needs and demands of a changing agriculture.

This period was notable for the first effort to substitute mechanical power for animal power. This was the steam engine, which appeared in the middle of the century and was useful chiefly as a mobile source of power for threshing machines. Occasionally these steam engines were used in plowing, in regions where the terrain permitted.

In the last decade of the nineteenth century many experimenters began work with the internal-combustion engine, looking toward the development of the tractor.

(Representative Sumners assumed the chair.)

Mr. McCORMICK. Commercial production of tractors powered by gasoline engines may be said to have begun in the first decade of this present century. Before the World War their use was widespread and during the war it greatly increased.

The basic tractor from 1910 to 1924 was a four-wheel machine useful mainly in preparing the seedbed and in harvesting operations. These tractors were intended to pull machines which were essentially of a horse-drawn type, although the construction of many such machines was strengthened to stand up under tractor use. In field work these tractors applied their power principally through the drawbar.

Two devices enabled the power of the tractor engine to be applied to related machines. The belt pulley made it possible to use the tractor to run stationary threshers, hammer mills, ensilage cutters and blowers, small sawmills, and other such machinery. The power take-off, through a drive shaft, operated grain binders, corn binders, corn pickers, potato diggers, and other machines with moving parts, thus making these machines independent of power from ground traction for the first time. In other words, before this time the mechanism of an implement pulled before by a horse was motivated by power derived from the wheel.

From this time forward the wheel became something simply to carry the implement, and the power necessary to move the mechanism of a binder or mower was derived by a shaft running from the rear end of the tractor to the front end of the implement. That made quite a revolution in machinery design.

Side by side with the growth of the tractor came another application of the gasoline engine to farm technology. This was the rise of the automobile and motortruck.

The importance of the automobile and the motortruck led a number of farm equipment manufacturers to enter that field during this period. No company in the farm equipment industry is now engaged in making passenger automobiles. Our company is the only one in the industry which manufactures motortrucks. I consider our motortruck business a contribution to technological advance on the farm in the same sense as our other products. Although our motortruck sales eventually became greater in urban areas than in farm areas, we entered the business originally with the needs of farm transportation foremost in view.

In this period, too, a third type of tractor was introduced, the crawler or tracklaying type. It appeared about 1905, and soon became available in several sizes. Its chief advantages are its great tractive power in hilly or loose soil conditions, and its relatively low height.

Small crawlers are used extensively in orchard work while larger ones have been adopted in many regions where great power on the drawbar is the principal need.

During these same years the large Pacific-type combine was adapted in a greatly reduced size to the smaller farms of the prairies. These prairie-type combines, having cutting widths of from 12 to 16 feet, became available about 1914.

Such developments as the power take-off, the belt pulley and the prairie-type combine added greatly to the utility of the tractor but it still could not perform one of the essential farm operations, the cultivation of growing crops. This did not become possible until the Farmall tractor was introduced in 1924.

The great contribution of the Farmall tractor was its ability to do everything the earlier tractors had done, and in addition, to cultivate row crops without injury to the growing crops. It made possible for the first time the application of tractor power to all field operations. It took the tractor out of the class of a partial substitute for animal power and made it unnecessary to keep horses at all.

The Farmall differs from standard tractors in that it is a 3-wheeled machine with a higher axle clearance.

It derives its traction from two large drive wheels at the rear, its steering from the small wheel centered at the front of the machine. Its rear wheels are adjustable to different row spacings and its design enables the operator to see the work he is doing better than with a four-wheeled machine. The popularity of this type of tractor has influenced all subsequent tractor design and has made all-purpose tractors standard in the industry.

I don't mean by that that the four-wheeled tractor is an extinct type of tractor, but it means that all manufacturers manufacture an all-purpose type of tractor at the present time. There is a use for four-wheeled tractors in certain sections of the country where row crops are not the all-important feature.

Under the influence of the all-purpose tractor the principal farm machines underwent a radical revision in design. An important phase of this change was the construction of machines not to be pulled by the tractor but to be mounted directly on it as quick-attachable tools.

The all-purpose tractors had their greatest usefulness in farming areas where row crops predominate, particularly in the Corn Belt and the Cotton Belt, where the previous four-wheel models had been of limited utility.

During this period between 1924 and 1932 the prairie combine underwent still further changes which tended to reduce its size and the width of its cut. Ten-foot machines and 8-foot machines were introduced.

The census of 1930 showed 900,000 motortrucks on farms. By 1935 manufacturers' estimates place the figure at nearly 1,000,000. I believe the 1940 census will show more than 1,000,000. The figure does not in itself reflect the importance of the motortruck in farm transportation, since much farm produce moves to market in common-carrier trucks. I know of no statistics covering the number of such trucks.

Before the present development of the motortruck, the farm viewpoint was bounded by the number of miles a horse could cover in a day. The farmer's market was the nearest market, unless he enjoyed an unusually favorable location on a railroad. There were costly delays in shipping. Stock lost weight, which meant dollars to the farmer, on the way to market.

By 1932, 40 percent of livestock went to market on the highways. By last year that proportion had increased greatly. Department of

Agriculture studies in October 1939 of 67 major markets showed that 58.8 percent of the cattle, 66.9 percent of the hogs, 58.4 percent of the calves, 40.5 percent of the horses and mules, and 25.7 percent of the sheep and lambs went to market by motortruck.

Aside from livestock marketing, I think it is probably not necessary to do more than refer to the obvious boon the motortruck has been to dairymen, fruit and vegetable growers in increased speed of delivery, widening of markets and lessening of spoilage losses.

Turning again to the field of farm machineery, the year 1933 was notable for the introduction of an all-purpose tractor substantially smaller and cheaper than any other theretofore built. This was the Farmall 12. While designed primarily for use with one plow for which it proved popular, it also developed that in many soils it had enough power for two-plow operations. Competitive developments in the one-plow tractor field immediately followed with the result that still smaller and cheaper one-plow tractors were introduced and a substantial demand from farmers for this small type of tractor has been clearly demonstrated. At the present time 4 or 5 of the tractor manufacturers of the country have one-plow tractors and those who have not will presumably have tractors of this type within a short time. Last year the Harvester Co. introduced two new one-plow tractors, smaller and substantially cheaper than its original one-plow tractor of 1933.

The year 1933 was also notable for the first introduction of a tractor with rubber tires as regular equipment. And you gentlemen, I am sure, noticed the large number of implements and tractors you saw with rubber tires in those pictures.

Since that date the increase in demand for rubber tires has been remarkably rapid until today the overwhelming majority of all tractors of all sizes made by all manufacturers go out on rubber.

Although rubber tires increase the first cost of a tractor their advantages more than offset their disadvantages. Their rolling resistance is much less than that of the steel wheel with lugs. Under most conditions, therefore, the use of rubber tires permits either higher speed of operation, or the use of larger implements, or a reduction in fuel costs while using the old implements at the old speeds.

By their cushioning action rubber tires save wear and tear on the tractor and, even more important, add greatly to the comfort of the operator. Furthermore, the rubber tire admits the tractor to the paved highway, either to move implements from field to field or for road hauling with a rubber-tired wagon. The utility of the rubber-tired tractor for road work is causing manufacturers to build greater speeds into tractors, and road speeds of 8 to 15 miles an hour are commonplace on current models.

In addition to the use of tires on tractors, an increasing number of wheeled implements, such as plows and combines, are being mounted on tires.

You will be interested to know that an effort is being made by our company, and I believe by other implement companies generally, to standardize the wheel sizes of implements on which rubber tires are desirable, in order that the farmer may equip his machine with second-hand automobile tires. Tires with worn-down treads no longer safe for automobile use can still give long and cheap service

on implements which are not required to furnish their own traction, but are drawn or powered by tractors or horses.

I might say at that point that one of the resistances to the introduction of rubber tires some years ago was just that fact of the first cost. There was a natural skepticism and doubt about whether the farmer was really warranted in adding that additional cost to his tractor or to his implement. There was a further question about the durability of tires on the farm. You men know that around a farm and out on country roads there are any number of nails and sharp things loose, and it was thought that the life of a tire might be short. That has not proven to be true.

Another thing that caused a resistance to the introduction of the rubber tire was the thought that it would not have sufficient traction under a large number of conditions. That hasn't been proved true either. It is true that under certain limited conditions, for instance frozen soil on which there is a little thawing on top, the rubber tire has not had the desired traction, but in other conditions you have either equal or better traction than another tire, and it looks as if it were here to stay.

The VICE CHAIRMAN. Does the rubber tire help to prolong the life of the machine?

Mr. McCORMICK. Yes, sir; it does very definitely, and it has another definite effect: When you take away by the use of rubber tires the sharp shocks, the shock of a steel lug on a hard surface, a frozen surface, for example, or a steel wheel hitting a stone, you are able to design your whole machine less heavily, less strongly, and therefore more inexpensively. The rubber tire has had a distinct influence on our being able to lessen and lower the cost of the tractor, and I believe that that will maintain to a degree in implements, although not to as great a degree.

Another notable development since 1932 has been the small combine. Prior to that date, the smallest combine had an 8-foot cut, and there had been sufficient sales of these machines east of the Mississippi to indicate that combine harvesting was not limited to the dry areas. The development of the small one-plow tractor naturally led to experimentation with small combines which could be pulled with the one plow tractor, operated with a power take-off and handled successfully by the operator of the tractor without other assistance. The Allis-Chalmers Co. was the first in the field with a successful small combine having a cut of 5 feet. Other manufacturers, including the Harvester Co., were soon in the field with small combines of their own designs having various cutting widths. At the present time the farmer has a wide range of choice of combines, with cutting widths varying from 3½ to 6 feet, all of which can be operated with small tractors.

One of the reasons for the popularity of the small combine is that it will harvest many other crops besides the grain crops which the larger combines were designed to handle. The small combines have harvested successfully almost 100 different kinds of crops. Some of the most important, in addition to the grain crops, are soybeans, clover, edible beans, lespedeza, buckwheat, flax, peas, and sorghum.

Time will not be taken to list other newly designed implements for use with the one-plow tractor other than to say that many spe-

cial machines have been recently designed and are now available. The result is that with the old implements formerly available and all of the new machines specially designed for use with the one-plow tractor, the purchaser of such a tractor can use it for practically all farm operations; that is, a complete line of implements is available and each purchaser may choose those needed in his operations.

Reviewing the technological changes in farm machinery since 1932 as listed above, your attention is called to the fact that in the main they relate to equipment for small farming, and that a remarkable number of new machines have been designed, put out and proved popular, within a short time. When the history of this period is reviewed at a later date, it may well be that it will stand out like the period of 100 years ago as a time of concentrated invention having a marked effect on the future of agriculture.

The inventions of 1831 to 1850, with their subsequent refinements, made possible the rapid development of our prairie States and the building of our industrial civilization. The recent technological advances in farm machinery from which the family-size farm will greatly benefit, may well become a bulwark to preserve this important part of our social structure.

There are in the States about 6,800,000 farms of which the great majority are family-size farms operated without hired help. The United States census figures indicate that only about 1 farm out of 7 has hired help. In the 1920 decade most of the tractors were used on the larger farms with the exception of the specialized small fruit and vegetable farms. This was largely because one-plow tractors were not available and many farmers who would like to have farmed with tractors did not feel justified in making the investment required for a two-plow tractor and its tools.

Because of the situation some dire prophecies were made that farm mechanization would lead to corporate farming and the elimination of the family farm. The development and production of the one-plow tractor and all of the small-tool equipment to go with it, reflects the determination of the family-size farmer to remain in business and his desire to share in the benefits of mechanization. Only in response to such a demand could the many small tractor and the many tools to go with them have been designed, produced, and marketed. The small farmer wanted an automobile and in many cases had one, purchased perhaps in the second-hand market. Not needing his horses on the road, he wanted to do away with the care and expense of horses on the farm and enjoy the savings in time and shorter hours made possible by the use of improved farm machinery.

With the mechanized equipment now available for small and medium-sized farms it seems reasonable to believe that the family farm which has often been called the backbone of our Nation will still stand and perhaps be in a stronger position than ever.

(Dr. LUBIN assumed the chair.)

Mr. McCORMICK. The foregoing is a very condensed outline of the technological progress in labor-saving farm machinery during the last century, with an indication of the pronounced present-day trends.

FARMERS' DEMAND FOR MECHANIZATION

Mr. McCORMICK. One conclusion seems fairly clear. It has not been the implement manufacturers who have directed the efforts of the

farmers, but rather the farmers who have directed and inspired the efforts of investors, engineers, and manufacturers to solve their problems and supply their needs.

The early implements were in many cases invented or designed by farmers themselves. Highly trained engineers now design farm machinery, but their efforts are naturally directed to the solution of the problems actually presented by farmers. These problems of demands for different kinds of equipment find constant expression in contacts with farmers and are transmitted to manufacturers through their sales and research organizations.

Now, Dr. Anderson, with your permission, if I could skip over to page 12, in the interest of saving time, the material covered there I would be very glad to discuss any questions which you might care to cover at a later date. We will go to the bottom of page 12, then.¹

(The material omitted appears below) :

Refrigeration has only recently become an important part of farm equipment, and is one more example of the industry's response to the farmers' demands. The demand began when health authorities required the cooling of milk on the farm before delivery to the cities, and it has been stimulated by the farmers' desire for household refrigeration.

Ordinarily not very many types of implements are required to handle the operations of a single family-sized farm, but most people would probably be astounded at the immense variety of implements and tools required for the many varied farm operations throughout the country, and also for similar operations under varying weather or soil conditions.

Progress in developing better implements, and by better I mean more efficient, more durable and less expensive, has been continuous and is still going on; but it is a gradual process, requiring field experimentals, including waiting periods between seasons for further experimentals.

MAJOR EFFECTS OF THE USE OF FARM MACHINERY

Mr. McCORMICK. As already noted, all the principal labor-saving devices for the preparation of the soil, planting, cultivating, harvesting, and handling of farm crops have been developed or invented within the last century, and during that time a continuous process of development and improvement has been going on. It is worthy of note that all this happened in our country and also that American manufacturers, unprotected by any tariff, have led the world in the manufacture of farm machinery, and that the American farmers have always been the greatest users of farm machinery.

It would seem, therefore, that the history of the last century should reveal in long-range perspective the effect of the use of farm machinery and the contribution it has made toward the progress of our country to its outstanding position in the world. The four major effects may be stated briefly as follows:

(1) Farm machinery has brought about an assured food supply and freedom from famine.

(2) Farm machinery, through enabling a much smaller proportion of the total population to produce food for the whole, has released from the soil the manpower which has made possible our great industrial progress.

(3) Farm machinery has done much to relieve the drudgery and shorten the hours of labor for that portion of the population remaining on the farms.

¹ Referring to prepared statement.

(4) Farm machinery has brought more profit to the farmers. (And not alone or mainly through labor displacement, but also in the many ways by which better yields and better quality of crops are obtained and assured through improved methods of soil preparation, planting, cultivating, and harvesting. The weather always will be one of the greatest farm hazards. The speed and timeliness of cultivation can do much to conserve moisture and effect weed control, and the speed of mechanized harvesting has greatly reduced the risk of losing matured crops through rain, hail, wind, heat, or other adverse weather conditions.)

(Senator O'Mahoney resumed the chair.)

Mr. McCORMICK. These four statements are self-explanatory, but I want to add a few comments on some of them, and in this connection discuss the subject of present-day labor displacement by farm machinery.

An assured food supply is a condition which never existed anywhere at any time in the world's history until it became a reality here within comparatively recent times. The change is so great that we no longer think of crop failure in terms of hunger and starvation, but rather in terms of the effect of a short crop on farm prices and farm income. We regard our food supply as so certain that we do not worry about the matter at all. Credit for this change belongs, of course, in part to the governmental and private agencies which have contributed to the control of pests and diseases, produced new and better varieties of plants, and improved the quality of livestock breeding and handling. But I believe the mechanization of farming between 1831 and the present day has been a foremost factor.

We can all remember the World War slogan, "Food will win the war." We can also remember that the machines available made it possible to bring about a vast increase in food production to meet the unparalleled demand of that period. I believe our unequalled capacity to produce food is the foundation of our strength from the standpoint of national defense. The present uncertain state of the world certainly brings home the vital importance of this productive capacity.

At present there are surpluses of some farm products, but in the main these are surpluses in the sense that they are not currently salable rather than in the sense that our people do not need or could not use the products. Regarding these surpluses, I am in substantial agreement with the views expressed by Dr. Mordecai Ezekiel, of the Department of Agriculture, before the National Industrial Conference Board meeting in New York last January.

Dr. Ezekiel gave it as his opinion that a level of industrial employment comparable to what existed in the 1920's would cause a substantially larger demand for farm products, and might even require an increase in acreage of some crops. He suggested that the more fundamental problem is how to put back to work the city people who are not working and are ready to work, and ready to buy more food for their families. When that problem is solved he believes the remaining farm problems will be comparatively simple of solution. I think that is probably true. And I have faith enough in the future of the United States to believe that these problems will be solved.

Next in importance to our assured food supply, and conditioned upon it, is the fact that without agricultural mechanization our industrial society would be impossible. Only when men were released from physical toil in the fields could they apply their strength and intelligence to the development of industry.

From the beginning of history until very recently the necessity of producing food by crude hand methods chained the vast majority of people everywhere to a life of hard labor on the land. Secretary Wallace has clearly stated the dramatic change that has taken place:

One hundred fifty years ago it required 19 people living on the land to support themselves and one person in town. Today, under greatly commercialized and industrialized conditions, one person on the land supports himself, 3 people in town, and contributes to the support of another person overseas.

The mechanization of agriculture, including farm transportation, made the farm population a great reservoir from which almost constantly man power has been drawn for the expanding industries that have made the United States the foremost nation of the world. For more than 100 years, right down to the depression of 1929, the pressure for release of men from farms to join the ranks of industry has never ceased.

This movement halted with the depression, and now the persisting industrial unemployment has made socially undesirable, for the present at least, this very process of release of men from the soil which for so many years was of social and economic benefit.

This brings us to consideration of the present situation. Naturally the question arises as to whether the continuing sale of farm machinery is aggravating the unemployment problem of the Nation.

First let us agree that farm machinery is labor-saving without question. No machines have ever been demanded or salable unless they enabled farmers to perform farm operations in less time and in a more efficient manner. That is their very purpose.

The CHAIRMAN. May I interrupt you there? Going back 1 or 2 paragraphs to your statement that for more than 100 years, right down to the depression of 1929, the pressure for release of men from farms to join the ranks of industry never ceased, do you mean to imply by that that industry is something new, or do you agree with me that it is merely a transfer of the situs of industry, so to speak?

Mr. McCORMICK. That is correct, Mr. Chairman.

The CHAIRMAN. Before the invention of the modern machine, industry was carried on on the farm.

Mr. McCORMICK. Going way back, before even city industry, yes.

The CHAIRMAN. Yes, and the story of our industrial development, the development of the factory system and the machine age, has been the story of the gradual transfer of industrial activities from the farm to the city as well as the story of the substitution of machine labor for hand labor.

Mr. McCORMICK. The substitution of machine labor for hand labor on the farm?

The CHAIRMAN. In the industries.

Mr. McCORMICK. Yes, I think of course that statement is true, with perhaps the addition that new industries were created in the cities which never did exist perhaps on the farm.

The CHAIRMAN. Yes; that is perfectly true.

Mr. McCORMICK. This only means to imply I think just what you mean, that there has been a demand as industry moved into and grew in the city, for this labor which now is freed from agricultural use to go into the industry. Of course that is a broad statement, and undoubtedly there were periods in the past where that process was held up, just as it is held up at the present time.

The CHAIRMAN. In other words, by reason of the inventions of thoughtful and skillful men and the discoveries of science, we are able as a race to produce many things which were impossible to produce 100 years ago, 50 years ago, even 10 years ago.

Mr. McCORMICK. Exactly.

The CHAIRMAN. In earlier days mankind had to be satisfied with what he could produce in the circumstances that then existed.

Mr. McCORMICK. That is right.

The CHAIRMAN. So industry is changing both its form and its locale, so to speak.

Mr. McCORMICK. Naturally, yes.

The CHAIRMAN. And our problem is, as you stated here, to provide for the absorption of those who may be thrown out of employment.

Mr. McCORMICK. That is true.

FARM MACHINERY AS LABOR SAVER

Mr. McCORMICK. But in appraising the effects of farm machinery, an important distinction must be made between labor saving and labor displacing. The labor hours saved by machines may be reflected in shorter hours for those working on the farm or in someone leaving the farm to seek other work. I believe both effects have occurred in varying degrees at different times and places.

There have been long periods when the attraction of city jobs led many farm workers, both hired hands and farmers' children, to leave the farm. During these periods the benefits of labor-saving machinery were mainly applied to replacing those leaving the farms, and in less degree to shortening the labor day of those remaining on the farm.

At the present time, however, and looking ahead, I believe it can be said with some assurance that the tendency is to shorten the hours of the workers on the farm rather than to decrease their number. The working hours of industrial labor have been substantially shortened by law, agreement, or custom. The farmers' working hours have been much longer than the hours of factory labor, and it is only natural that they should desire shorter hours and also relief from the most back-breaking farm operations.

In addition, there is the important fact already mentioned that the great majority of farms are family farms without hired help where no labor displacement takes place, as farmers do not fire themselves or their children when the time required for farm operations is shortened. These farmers earnestly desire the help of machinery. They constitute the great market for which the newer and smaller tractors and implements are being made and on which the farm-equipment industry is pinning its hopes.

When farmers think of labor-saving machinery, they are thinking primarily in terms of shorter hours and release from physical labor of the most wearing kind, and secondarily of the cost reduction which

in many cases results from and can be obtained by the improved methods of production and handling of crops made possible by machinery. Any farmer who has ever walked 15 miles a day in the furrow, wrestling every foot of the way to keep the plow in a true course, knows what the tractor and the tractor plow really mean.

Anyone who has ever plodded through a cornfield in freezing fall weather, husking by hand, knows what a blessing the mechanical corn picker is in terms of labor saving.

This kind of labor saving has small effect on employment. Its main effect is in shortening the working day for the family group, father, mother, and children, and making the group work more efficient, more pleasant, and more profitable. Farming, as has been said many times, should be a way of life as well as a way of earning a living. Labor-saving machinery has contributed much to a more attractive way of living for the farm family, and it will contribute more.

We know there has been an improvement in rural educational facilities. We can see it in the new consolidated schools and in the growth of the agricultural colleges. That growth could not have taken place unless young people had been released from work by machines.

We know there has been an increase in the social opportunities of the farmer and his family. We need only consider as one example the really wonderful work which has been done and is being done through the 4-H Clubs to train farm children for better living. We know that before mechanization, such a program could not have been carried out.

We observe that the Federal Government through the Rural Electrification Administration is itself concerned to extend mechanization on the farm by making available a new source of power.

In short, farm life can be made more attractive than it ever was, and is being made so, and the farmers want it that way. There is no longer the vast gap between farm living and customs and city living and customs which once existed and there should not be.

In this connection I should like to quote from a radio address by S. H. McCrory, Chief of the Bureau of Agricultural Engineering, delivered July 22, 1938. Speaking of the effect of machinery on the farmer's way of living, Mr. McCrory said:

He must still keep close to his work, but he has been given such able assistants he can lift his nose from the grindstone of the past and give more attention to the business of farming and living.

While stressing the major effects of farm machinery and shortening hours, I do not mean to imply that farm machinery has brought about no recent labor displacements. No doubt it has brought about such displacements, but not, I think, to any such extent or to the degree which has occurred in industry. In addition to the family size farms there are, of course, larger farm operations in various parts of the country employing hired labor which have had and are having difficult times on account of the low prices of their products. Such farms, if they are to survive, must be operated in the most efficient way to achieve the lowest costs and this in some cases has brought about the use of machinery to reduce the amount of hired labor.

These situations parallel to a certain extent industrial operations. I firmly believe that the best interests of our society as a whole are served by encouraging technological advances tending to bring about the production of cheaper, better, and more goods for general use. But no intelligent person, and no one of good will, would ignore the fact that the benefits of such progress are sometimes achieved at the cost of temporary labor displacements involving hardships and readjustments. The answer, I believe, lies in recognizing these situations as social problems to be handled with sympathy and with policies calculated to alleviate the hardships of the necessary readjustments.

The extent of labor displacement by farm machinery is sometimes exaggerated by confusion with other causes. Nature smiled during the 20's on the settlement of the semi-arid areas of the Midwest plains. Then followed many successive years of cruel drought, want, and poverty. Naturally this led to migration, and the lure of an Eldorado where a certain amount of migrant labor was needed led to the concentration of this migration and its dramatization.

Straight thinking on the problem may be easier if we consider what would be a sound national policy for the resettlement of these unfortunate people. Surely they should not be returned to the dust bowl now that we know how severe and prolonged the drought periods can be. The human hazard of concentrating populations in such areas is too great. To the extent that a sound national-conservation policy would include the use of these lands for farming operations, it would seem advisable that they be conducted with a minimum amount of population and maximum efficiency of mechanization. Only in this way can the human and economic hazards of drought be minimized.

Bearing on the effects of farm machinery on the farmer's income, the National Resources Committee in its study of technological trends and national policy says:

That the income of the agricultural worker tends strongly to increase with increase in power and machinery available for his use is indicated in comparing by states the average gross annual income, available power, and value of farm mechanical equipment. * * * Fragmentary data from foreign countries seem to indicate that throughout the world increase in the amount of power available, within the limits observed, tends to increase the income of the agricultural worker.

This increase in the income of the agricultural population, through mechanization of the farm has also been of importance to urban industry in maintaining a market for its products, since the ability of the farmer to buy industry's product depends upon his income. I do not believe that the American type of high-volume, low-cost industry could have developed in connection with a backward, underpowered agriculture.

The extended use of labor-saving machinery on the farms of the Nation is indispensable if any fair balance is to be maintained between the farm worker and the industrial worker with respect to their ability to produce and exchange their products.

FUTURE TREND TOWARD SMALL MACHINES

Mr. McCORMICK. No one, of course, can predict what the future may hold. But some things about the future may be said, I believe,

on the basis of what has happened in the past. On that basis, I believe the future will witness continued progress in the application of mechanical power to farming. I believe the changes will be gradual, as all changes in agriculture are. I believe that they will come in response to the changing needs of the farm population. I believe that they will have the same objectives as before—to increase the farmer's income and improve his way of living. I am convinced that the pronounced trend toward smaller machines will continue and that the end result will be to improve the position of the family-sized farm which has always been held as the ideal basis for American farming.

(Appendix A to Mr. McCormick's testimony, which was not read, follows:)

At the request of Mr. H. Dewey Anderson of the committee, the following brief sketch of the organization of the farm-equipment industry has been prepared.

Prior to the Civil War the manufacture of farm machinery was carried on in small factories, each of which usually produced only one type of implement, and many of which were owned by local mechanics or blacksmiths.

As the industry grew, individual manufacturers tended to make more than one implement, but they generally confined themselves to one classification of implements. A plow maker, for instance, might add to his list of products such other tillage tools as harrows and cultivators, but was not likely to engage in the thresher business.

In this way the industry by the end of the last century had developed several fairly well defined branches. These might be enumerated as plows and tillage tools, drills and planters, threshers, wagons, spreaders, engines, harvesting machines and cream separators.

The turn of the century saw a trend toward consolidations of companies in this industry, as in several others, which resulted in larger units, and which also resulted in a tendency to broaden the range of implements supplied by the individual company.

The impetus toward broadening the line of products came from the system of distribution of implements. Most manufacturers had found it necessary to maintain wholesale branch sales houses in various parts of the country to handle their sales, since unaffiliated wholesale houses often lacked either the knowledge or the energy required to promote the sale of new or little known implements. Maintenance of these branch houses, however, was expensive when only a single line of implements was sold, because of the seasonal nature of the business. The tendency toward broadening a company's line resulted from the desire to have something to sell at each season of the year.

This tendency has led to the growth of 8 companies which are known as long line companies. They are Deere & Company; J. I. Case Company; Allis-Chalmers Manufacturing Company; Oliver Farm Equipment Company; Minneapolis-Moline Power Implement Company; Massey-Harris Company, Incorporated; B. F. Avery & Sons Company; and International Harvester Company.

In addition to these "long line" companies, there are many smaller concerns engaged in manufacturing lines which range from a single machine, such as a cream separator, to a line of implements and machines of considerable length. Among the more important "short line" companies are New Idea, Inc.; Avery Farm Machinery Co.; Gleaner Harvester Corp.; Dempster Mill Manufacturing Co.; Stover Manufacturing & Engine Co.; A. B. Farquhar Co., Ltd.; Lynchburg Foundry Co.; Papec Machine Co.; Wood Bros. Threshing Co.; Ann Arbor Machine Co.; DeLaval Separator Co.; Anker-Holth Manufacturing Co., Inc.; Ohio Cultivator Co., and Farm Tools, Inc.

In all, the "long line" and "short line" companies engaged in the farm equipment industry total approximately 200. To these should be added 2 of the large mail order houses, Sears, Roebuck & Co. and Montgomery, Ward & Co., both of which engage in the selling of farm machinery on a large scale, and the Ford Motor Company, which has recently reentered the farm equipment field and is now marketing a tractor with some implements.

The majority of agricultural implement factories are located in the Midwest, especially in the state of Illinois, Indiana, Ohio, Wisconsin, Minnesota, and Iowa, although factories are to be found also in such other States as New York, Penn-

sylvania, Kentucky, Nebraska, Tennessee, and Michigan. A number of specialty implement factories are on the Pacific coast because of the special requirements of West Coast agriculture. The Midwest has been favored as a manufacturing area because of its central location, its transportation facilities, and its position in the heart of a rich farming area suitable for mechanized cultivation.

Probably the two most important districts in manufacturing are the Chicago-Milwaukee district and the Rock Island-Moline-East Moline-Davenport district.

Individual factories tend to specialize on certain related groups of machines and implements rather than to make many products. A factory may thus make only tractors, tillage tools, or harvesting machinery. There are, however, numerous exceptions.

The distribution system of the larger and many of the smaller companies is usually national in scope. The sales unit of the manufacturer is the company-owned branch house, whose territory usually embraces a number of counties and may even, in sparsely settled regions, take an entire state or parts of several states. The branch houses sell to dealers in the local communities who in turn sell the goods to the users.

The blockman, or wholesale salesman, is the principal contact of the manufacturer between the manufacturer's branch house and the local dealer. It is his responsibility to secure dealers, to assist them in merchandising, to advise them on stocking machines and repairs, and to help, when needed, in closing sales. Ordinarily there are 8 to 10 blockmen to each sales branch.

The branch houses at all times carry large stocks of new machines and of factory-made repair parts which are available both to dealers and users of the machines. The maintenance of adequate repair stocks is vital, since any long loss of time due to the breakdown of a machine means a considerable monetary loss to the farmer.)

The CHAIRMAN. I note with much interest, Mr. McCormick, the statement that the answer lies in recognizing these situations which you have described as "social problems which are to be handled with sympathy and with policies calculated to alleviate the hardships of the necessary readjustments." I assume from what you have said that you regard this policy as one of national responsibility.

Mr. McCORMICK. Yes, sir; I do.

The CHAIRMAN. Policies to be undertaken by the Government.

Mr. McCORMICK. Where the localities are unable to handle them, the national Government certainly must take care of them.

The CHAIRMAN. Have you given any thought to the particular policies that might be adopted?

Mr. McCORMICK. No, sir; I haven't. Naturally we all think about those things, but I am unable to give anything of a definite nature in that way.

The CHAIRMAN. Of course, there are certain national policies, for example, reclamation, which is of great interest to those of us who come from the so-called arid-land States. The Reclamation Service was first established in 1902, and many large reclamation projects were undertaken. Later the feeling grew up that we had too much farm production and for many years the Federal contribution by way of appropriation to the building of new reclamation projects was delayed. Practically one might almost say it was abandoned. In my own State, in Wyoming, though that State contributed by way of oil royalties to the public domain, millions of dollars to the reclamation fund, more than \$25,000,000, for example, came out of a single county in my State into the reclamation fund, there was no attempt at all to expand the reclamation projects in the State or to develop new ones. During the last 7 years new reclamation projects have been constructed and are now under construction in various of the States, and some of these Dust Bowl families to whom you have alluded are being settled on these new lands. You

don't regard that as an undesirable policy, do you, from what you stated here?

Mr. McCORMICK. I think, Senator, that my opinion on individual matters isn't worth very much. I think, in general, we have to take care of temporary situations, that is all there is to it. In other words, when distress arises in a given section of the population, it must be taken care of. Aside from that, the only position I could take would be that whatever is for the permanent good of the farmer in each individual case is what we want.

The CHAIRMAN. Your use of the word "permanent" points again to the real significance, we need a permanent policy.

Mr. McCORMICK. That is right, not a flash in the pan or a thing that isn't fundamentally sound, but something which year by year we can build on as a permanent thing.

The CHAIRMAN. You have no suggestion to make on that?

Mr. McCORMICK. I have no suggestion.

The CHAIRMAN. Who buys the farm machinery you manufacture?

Mr. McCORMICK. On the whole, speaking generally, we, the manufacturing company, sell to dealers and the dealers are those who sell to the farmers.

The CHAIRMAN. Do the dealers in farm machinery, like the dealers in automobiles, absorb the difficulties that are inherent in the used tractor, the used machine?

Mr. McCORMICK. The situation is very similar. In many instances they take a trade-in, in some cases recondition it and resell it.

The CHAIRMAN. When you dispose of your product to the dealer, your story is told.

Mr. McCORMICK. That is right, Senator, in general.

EFFECT OF TENANT FARMING ON MECHANIZATION

The CHAIRMAN. So that you don't have any figures, certainly no experience, with respect to the relative importance of the tenant as a purchaser of these machines?

Mr. McCORMICK. No; I wouldn't have any—do you mean as a purchaser of a second-hand machine?

The CHAIRMAN. Of any machine. You see, the testimony is here, and it is clear from the census returns that the number of tenant farmers is steadily increasing.

Mr. McCORMICK. Yes. I am sorry I wouldn't have any concrete information that would be of any use as to what proportion of our sales went to tenant farmers and what went to owners.

The CHAIRMAN. Do you think it would be a reasonable assumption that the tenant farmer is unlikely to be as good a purchaser as the owner?

Mr. McCORMICK. I would rather have the feeling that it would depend a great deal on the individual and his capacity, ability, and financial worthiness rather than whether he was a tenant or owner. That is just an offhand statement.

The CHAIRMAN. Well, the figures presented to us indicate not only an increase of the tenant farmer, but also an increase of what might be called institutional farming, that is, corporate farming, the ownership of farms by corporations. Insurance companies, for example, have been compelled, through no choice of their own, but by reason of the depression, to take over many farms.

Mr. McCORMICK. Yes, and if that is the case, and farming can come back to a more profitable position, wouldn't we consider that part of it a temporary phase, that wouldn't be an underlying trend toward larger farms in that particular connection. In other words, insurance companies, as you say, are not taking those farms because they like to do it, they have to, and I understand they are trying to put them in good condition and then sell them. So, after the end of that cycle, you might say of transfer of ownership, those farms I should think would revert to individual owners.

The CHAIRMAN. That may be true to some extent, but the steady increase of the proportion of tenants seems to be independent of the depression.

Mr. McCORMICK. Oh, yes; that is a quite different thing.

Dr. ANDERSON. I wonder if you could discuss the used farm machinery market, and tell us whether the used farm machinery market offers a possibility to farmers in lower circumstances to mechanize their operations and compete successfully with other farmers who buy original and new equipment.

Mr. McCORMICK. Dr. Anderson, I think there is no question about that. It is entirely parallel to the automobile situation. The used tractor or the used implement does go toward supplying the farmer with the lower income so that he can have the benefit of mechanization without the cost of the original equipment.

With your permission I should like to read that section of my printed statement, if I may.

An effective factor in extending the benefits of farm machinery to a larger proportion of the farmers has been the development of resale markets in which serviceable used equipment of many kinds is being purchased at prices substantially below the cost of new equipment. This development has been greatly accelerated since 1935. Most of the tractors in use during the depression were manufactured in the late '20's. The improvement in farm income which took place after the worst of the depression, together with the improved machines offered by the industry, resulted in extensive buying of new tractors and implements and the trading in of the old machines and these old machines after reconditioning were in turn sold to other farmers.

We estimate that currently about 80 percent of the sales of new tractors involve the trading in of an older tractor. Naturally, the percentage on these very small tractors that are now being introduced to some farms which have been exclusively horse or mule farms before won't have as high a percentage of trade-in as that.

This makes tractor power in the form of a used tractor available at low cost to farmers who might not otherwise obtain it.

You gentlemen are probably familiar with the somewhat similar situation in the automobile industry, where a very large proportion of all automobile owners have never owned anything but a used car.

In the case of farm equipment, the potential usefulness of a machine purchased at resale is even greater than usual as the industry has an outstanding record of good repair service on old models which are no longer in production.

The result is that the purchaser of a used tractor is able to get parts and service and need put no arbitrary limit on the length of time he will use the machine. As a matter of fact, no one knows what the life of a tractor is. The first Farmall tractor ever sold, which was manufactured in 1925, is still in daily use on an Iowa farm.

The history of the motor truck on the farm parallels that of the tractor. Here again the resale market and the practice of reconditioning machines for resale has made the motor truck available at very low cost.

Dr. ANDERSON. Mr. McCormick, yesterday when we were examining this question with the experts in the Department of Agricul-

ture we were given some depreciation figures that would not be in line with the statement you have just made. The indication was then that depreciation was relatively high and replacement necessary within a rather brief period of time. Carrying out the statement you have just made, that this first Farmall tractor ever sold is still in operation, is it your judgment from your observation of the industry that the depreciation period is relatively high or not?

Mr. McCORMICK. I would say that any time that we sold a tractor that you couldn't use for more than 5 years we would be cheating the man out of his money.

Dr. ANDERSON. In other words, a person buying farm machinery and installing it on his farm has a prospect of a life of, what would you guess for the tractor?

Mr. McCORMICK. I would put the lowest figure at 8 years, the very lowest. I would say that 10 years should be a fair average. Just as I say here in this paper, the first Farmall is being used on an Iowa farm and that is 16 years. That isn't the only one. We have got thousands and hundreds of thousands of them still out, and I am quoting just from memory now and I can't back it up, but it seems to me that I have seen figures which indicated there were some hundred thousand Fordson tractors still in use. The Fordson tractor was last produced in 1927, which would make those tractors at least 13 years old.

Dr. ANDERSON. What is this process of mechanization? How does the farmer go about becoming mechanized, changing over from the horse to the tractor?

Mr. McCORMICK. Well, that is a pretty broad question to answer, and I should like to know if you mean that in a rather historical sense, or if a man who had been just a horse farmer up to today were to change today.

Dr. ANDERSON. What does he do today?

Mr. McCORMICK. What kind, an Iowa corn farmer?

Dr. ANDERSON. Take an Iowa corn farmer, to make it specific.

Mr. McCORMICK. If he were a horse farmer up to today he would naturally be preparing the soil with horses. He would have presumably a horse plow, probably a 2-bottom gang plow; he would have a horse disk; he would have a horse peg-tooth harrow, or smoothing harrow. Suppose he was going to start in at the beginning of the year to prepare his soil, he would have to buy his tractor; some of those things it would be difficult to do with the plow; he could do it to a lesser extent, not quite successfully, with a harrow; he might cut his tongue off and try to make a tractor hitch out of his horse hitch. He might use that for the first year, and maybe the second year, I don't know, but he wouldn't be satisfied with it very long. Let's say that he wasn't satisfied with it when he first tried it out in the field, and he went to the dealer, and said, "That doesn't work very well, I think I'll just have to buy a tractor disk," then he would buy a tractor disk harrow which would cover the ground faster than the horse disk; he would buy his peg sections that he could use behind the tractor; he could put on new chains behind the tractor.

COST OF MECHANIZING A SMALL FARM

The CHAIRMAN. What would be the capital investment, let's say, for a 50-acre farm?

Mr. McCORMICK. Well, Senator, that is a very difficult question to answer, because we have to decide whether we are going to talk about new price, or, what most farmers do, buy some new and some old.

The CHAIRMAN. Well, of course, there would be a change of capital invested. He would dispose of his horses.

Mr. McCORMICK. Yes.

The CHAIRMAN. And buy the machinery.

Mr. McCORMICK. Yes.

The CHAIRMAN. Comparatively speaking, by and large what is the relation of those two items?

Mr. McCORMICK. Well, that is a difficult figure to arrive at. We had yesterday, I think it was in Dr. Johnson's testimony, if I can find it, some figures given here that I will just cite for reference, speaking of an Iowa farm. Dr. Johnson gave \$2,445.

Mr. PIKE. That is for a 160-acre farm?

Mr. McCORMICK. That is for a 200-acre Corn Belt farm.

Colonel CHANTLAND. That didn't include a wheat combine, then.

Mr. McCORMICK. I don't believe he had a wheat combine included. I don't know just what was included. They don't give the list.

Colonel CHANTLAND. What is the retail price of your small combine, ordinarily?

Mr. McCORMICK. The smallest we are manufacturing this year is \$405, retail price, a 4-foot machine. The next size is a 6-foot machine that retails for \$665.

Colonel CHANTLAND. And the retail price of this Farmall 12 tractor?

Mr. McCORMICK. The new one, Colonel?

Colonel CHANTLAND. Yes.

Mr. McCORMICK. In one-row size that lists at \$515. In the two-row, which is a little change-over of that same machine, it lists for \$535.

Colonel CHANTLAND. And you figure the average life of that is 10 years?

Mr. McCORMICK. We would be ashamed of it if it didn't last 10 years.

Colonel CHANTLAND. What about the life of a combine? I suppose that is a matter of housing?

Mr. McCORMICK. That is a great deal a matter of how the farmer takes care of his machine. There are many combines being operated in Kansas and Nebraska and other wheat sections that I venture to say were bought in at least the late twenties. I don't know why with good use a combine should not last 12 to 15 years.

Colonel CHANTLAND. Suppose we take what we would call a reasonably diversified Iowa farm, including, then, a combine. Would you feel that that \$2,400 figure or a \$3,000 figure as an initial investment would be reasonable?

Mr. McCORMICK. I am just giving it to you off-hand.

Colonel CHANTLAND. For all the implements needed? I think you ought to include in the implements needed the grinding and storing of it, ought you not?

Mr. McCORMICK. I should say that it would come to some place in that neighborhood, although I would have to sit down and add up this thing. Let's say some place between \$2,000 and \$2,500. I am just giving an off-hand figure. Let's say between \$2,000 and \$3,000. I think that might be a little more accurate.

Colonel CHANTLAND. Your exhibit 2682 shows that the average per year for '39 has gone up to 442. I don't quite know what that means. I suppose that is maintenance and replacement. That is the last of your exhibits.

Mr. McCORMICK. Will you say that again? I am sorry I missed that.

Colonel CHANTLAND. Well, it shows down at the bottom, there, 422 as the 1939 figure. I take it—

Mr. McCORMICK (interposing). That is millions of dollars of expenditures for farm implements, tractors, and repairs. That won't give you anything comparable there.

Colonel CHANTLAND. I see up above there in your 100-percent circle, you have the machinery down to 3.2 of the farmer's dollar.

Mr. McCORMICK. That is a question of the proportion of the farmer's cash outlay or dollar used in different ways. That item of 3.2 represents the purchase; in other words, that is his cash outlay for his farm implements, his tractors, and his repairs.

Colonel CHANTLAND. I was just wondering whether that is his initial expense.

Mr. McCORMICK. It is initial. It is, in other words, whether he buys a machine for the first time or if he replaces it when he gets his second machine. It is whatever he spends for equipment. That is not the cost of operating. Down here at the bottom you have another operating figure.

Colonel CHANTLAND. I understand that.

The CHAIRMAN. How does that capital investment in machinery compare with capital investment in animals?

Mr. McCORMICK. Well, we have the figure given here by the gentlemen yesterday, the figure they gave on this Corn Belt farmer, "Investment in equipment and horses, \$2,265. Investment in tractor and equipment, \$2,445," or a difference of \$180.

The CHAIRMAN. Do you accept that as being reasonably accurate?

Mr. McCORMICK. I would say so, in general. I wouldn't want to be committed to it, because I haven't studied it, Mr. Chairman.

The CHAIRMAN. Do you care to make any comments upon this other phase of the transfer, from horse power to motor power, that when horses were used for motor power on the farm, the farmer raised his own fuel, so to speak?

Mr. McCORMICK. That is true.

The CHAIRMAN. Because he raised the feed. Today the farmer buys the fuel.

Mr. McCORMICK. That is true.

The CHAIRMAN. Now, what is the effect of that change?

Mr. McCORMICK. The effect of that, naturally, was to take a certain amount of crops on a certain number of acres that were used for feeding horses and the crops from those acres then were transferred to other uses, such as increased livestock on the farm, increased dairy cattle, and other livestock, which are consuming a great proportion of that.

Another thing that happened, strikingly in my home State of Illinois, a new crop, the soybean crop, has grown in the last 10 years to absorb millions of acres. I won't say just the number; that may be an exaggeration, but a great number in Illinois, which forms, probably, some of the feed.

The CHAIRMAN. Did it contribute to the farm surplus of which we talk so much?

Mr. McCORMICK. Not in this particular way. The soybeans weren't a surplus; they are a growing size crop in this country.

The CHAIRMAN. Of course, it has increased our own self-sufficiency.

Mr. McCORMICK. That is right. Instead of importing these we grow them ourselves.

The CHAIRMAN. I noticed with interest that you spoke of the need of new farm machinery in the raising of sugar beets.

Mr. McCORMICK. Yes.

The CHAIRMAN. Experimentation with the development of such machinery, of course, is going on.

Mr. McCORMICK. It is important in your State.

The CHAIRMAN. Very important in my State, and, of course, the development of such machinery would do away completely with the problem of child labor on the beet farm, if it weren't already done away with substantially by the Sugar Act, and it would tend to reduce the problem of hired labor.

Mr. McCORMICK. Yes. There are certain cases like that, Senator, that you have mentioned.

We had a case the other day. I read in the newspaper of a group of people, I think in one of the Carolinas, who were clamoring for some machine to help them with their peanuts. They had a certain labor situation which was bothering them there, and they didn't come to us. We just saw in the paper that somebody was trying to work that problem out. The present farm mechanization is just a series of such instances, one after the other.

The CHAIRMAN. And as we continue technological advance with information from the farm, does it follow that we become increasingly independent of the foreign sources of supply?

Mr. McCORMICK. Well, I don't think mechanization—

The CHAIRMAN (interposing). Because machines make us capable of developing our own?

Mr. McCORMICK. I don't think mechanization can claim the sole credit for that. I think many other agencies, such as governmental agencies experimenting with new crops, various agricultural agencies and research people, are all doing that, but to the extent a new machine would be needed, it would be our job to see if we could develop a machine for the new crop.

The CHAIRMAN. And does it make it necessary for us, if we are to take full advantage of technological gains, to make ourselves independent of the supplies of given commodities, agricultural commodities which may be secured from areas not as advanced, technologically, as we are?

Mr. McCORMICK. That is a pretty deep question, Senator.

The CHAIRMAN. You don't want to go into it? Very well, I will pass that.

Mr. McCORMICK. We are getting into pretty wide fields.

CREDIT POLICY OF INTERNATIONAL HARVESTER

Dr. ANDERSON. Getting back to this question which I think is of fundamental importance, how the farmer becomes mechanized. Your thesis is that mechanization, and particularly the all-purpose tractor, has now made it possible—as a matter of fact you went on to say pointedly that this perhaps means the saving of independent farm ownership on the small farm. How available is mechanization to the average farmer? You pointed out that he turns in part of his old equipment, he turns in his horses. He doesn't make any such cash outlay, does he, as \$2,445 right on the spot?

Is it important for him to become mechanized without any considerable cash outlay?

Mr. McCORMICK. That would depend a great deal on the locality in which he is. In other words, our credit terms in one part of the country are more stringent than they are in others, naturally. If he had—of course I am speaking again second-handed, because as the Senator has brought out, it is the dealer who does this and we don't have any part in it except in a few minor instances—if he had, for example, horses and maybe some horse equipment to trade in, it is very likely that a good dealer could arrange to take the horses and horse equipment in as a down payment and perhaps more. In other words, that equipment, depending on the amount of equipment he was going to buy, might be sufficient to handle his down payment so he could go into farm powering.

Dr. LUBLIN. What is the maximum period of credit extended for these purposes?

Mr. McCORMICK. The maximum period we extend is 30 months. One may say, "Why 30 months?" The general thing is that we endeavor to give the farmer 2 crop periods in order to enable him to pay for his equipment.

Colonel CHANTLAND. He can raise a 2-year-old steer in that time, too.

Mr. McCORMICK. Yes; he could do that.

Dr. ANDERSON. In other words, Mr. McCormick—

Mr. McCORMICK (interposing). That is the longest. The average is far below that, very far below that.

Dr. ANDERSON. He has approximately two growing seasons in which to move into mechanization on a growing scale?

Mr. McCORMICK. That has been the custom of the farm equipment industry practically since its inception.

Dr. ANDERSON. Does the farm equipment industry itself underwrite these credits?

Mr. McCORMICK. We do. There are some companies which to a greater or less degree have finance companies finance some of their paper. Local banks do quite a bit of farm equipment financing, and we do the balance.

Dr. ANDERSON. And, in your judgment, then, the benefits of mechanization to the small independent farmer are not in any serious way impeded or denied by reason of a credit structure that is not suitable, or by his failure to have access to the machines themselves?

Mr. McCORMICK. No, sir. We endeavor, and we have been doing it increasingly as the years have gone on and our experience has grown, to suit our credit policy to the individual and to get away

from broad classifications which might be unfair or bad business. We have been endeavoring to fit these credit policies to the individual. In any size of farm, I would say, and almost in any category, there would be men who could buy equipment. There is no question about it.

The CHAIRMAN. The committee will stand in recess until 2:30.

(Whereupon, at 12:45 o'clock, a recess was taken until 2:30 p. m. of the same day.)

AFTERNOON SESSION

The hearing resumed at 2:30 o'clock, upon the expiration of the recess, Representative Hatton W. Sumners, the vice chairman, presiding.

The VICE CHAIRMAN. The committee will please come to order.

Colonel CHANTLAND. I think, Mr. McCormick, we left one open before the lunch period. What I was trying to find out was whether you had or whether the figures given yesterday indicated at the present time how many tractors were out and actually in use on these 6,800,000 farms that you gave as a figure for the United States.

Mr. McCORMICK. Colonel, we have an exhibit here that was submitted yesterday by Dr. Johnson,¹ giving the trend in numbers of tractors on farms from 1915 to 1939, which would indicate that at the end of 1938 there were something over 1,500,000 tractors on farms.

Colonel CHANTLAND. Were they on farms or is that the number that had been sold? Did they take into account any obsolescence?

Mr. CORMICK. I would assume, without knowing exactly the date on which this is based, that would represent an actual census on farms. I might be mistaken.

Colonel CHANTLAND. Just one other question on this last exhibit²—let's get that out of the way.

I was trying to make something out of that last figure. That is total expenditures per annum for all farm implements, isn't it?

Mr. McCORMICK. All purchases.

Colonel CHANTLAND. Not mechanized or anything else.

Mr. McCORMICK. What distinction—do you mean not necessarily power-driven?

Colonel CHANTLAND. That is what I mean.

Mr. McCORMICK. All farm equipment, tractors, and repairs.

Colonel CHANTLAND. And we can't tell how much of that is new, replacement or maintenance.

Mr. McCORMICK. That is correct.

Colonel CHANTLAND. So there is no use of trying to do anything with that figure as applied to what you are talking about here.

Mr. McCORMICK. Except that one could say from the chart that that was the total outlay of a farmer for his equipment.

Colonel CHANTLAND. But we don't—

Mr. McCORMICK (interposing). We can't correlate it.

Colonel CHANTLAND. As to your problem.

Mr. McCORMICK. No; as to the cost of equipping the individual farm, for example.

Dr. ANDERSON. But we do know that the percentage of farm machinery expenditure to gross farm income rose from 1931 to 1937, dropped slightly in '38, and again in '39.

¹ See "Exhibit No. 2655," supra, p. 16948.

² See "Exhibit No. 2682," supra, p. 17005.

Mr. McCORMICK. That is correct.

Dr. ANDERSON. In other words, there was a gradual increase, a rather gradual increase, in the percentage of farm machinery expenditures as compared with the gross income.

Mr. McCORMICK. That is a cyclical feature, of course. The farmer, of course, purchases in proportion to his estimation of his ability to buy, and when his prices are reasonable and his income is expected to be good, he invests more in equipment than he would otherwise.

Dr. ANDERSON. And if we took the high point of 1937 with over \$10,000,000,000 of farm income, we have the highest percentage expenditure as well for farm machinery.

Mr. McCORMICK. That is correct.

Dr. ANDERSON. In other words, in an especially good year he buys more machinery and becomes mechanized faster in good years than in bad.

Mr. McCORMICK. That is characteristic of the industry at all times.

Colonel CHANTLAND. And, of course, on any gross at the top is where the net comes from, so that the small addition to the expenditure might mean considerable increase in the net.

In other words, you have to go up to a certain percent before you make cost, don't you, in your gross—on anything?

Mr. McCORMICK. Yes.

Colonel CHANTLAND. So that the top part is the net; so that a small percent of increase in expenditures here might be a very good thing—

Mr. McCORMICK (interposing). Toward stimulating the top part—

Colonel CHANTLAND (interposing). Which is the net.

Dr. ANDERSON. Mr. McCormick, before lunch the chairman asked about the cost of mechanizing a given sized farm. I understand that you have a compilation on that point.

Mr. McCORMICK. Yes, Dr. Anderson. Some of my associates furnished me here with roughly retail prices on typical implements to equip a family farm in the 50-70 acre plats. We assume that on that farm a man would use a small tractor, a 14-inch tractor plow, a 1-row cultivator, a 2-row planter, 1 of the small combines, and a disk harrow. The total cost of that equipment, retail, f. o. b. factory, would be \$1,207.

Now, on the assumption, which is justified in most cases, that that man was a horse farmer previously, he naturally had a team or two of horses and some horse equipment. It is impossible to estimate what the value of that equipment would be in a trade-in at the dealer, but assuming that it ran, to be conservative, \$250, which I believe would be low—I think, if he had a good team of horses, he would probably get better than that—but just for the sake of argument suppose it was \$250, he would have a net balance to pay of \$957.

The VICE CHAIRMAN. I don't believe I followed you there. What are his horses worth? Would you assume he would retain his same team of horses?

Mr. McCORMICK. I was assuming that by buying the tractor he would be able to sell at least a team of horses.

The VICE CHAIRMAN. This farm that you have in mind—is that a 2-horse farm?

Mr. McCORMICK. It might be a 4-horse farm, but if he bought a tractor he might say, "Well, I will keep a team of those horses, and I will trade in a team." Just assuming for the sake of argument (this is purely hypothetical) that he did trade in a team, and some other equipment; for instance, a horse cultivator and a horse plow—

The VICE CHAIRMAN (interposing). You have started in with new machinery?

Mr. McCORMICK. That is correct.

The VICE CHAIRMAN. Wouldn't it be better if you had figured on the cost of installing it? But I won't disturb your figures, though.

Mr. McCORMICK. It is just on the assumption, you see—that he was an entirely new farmer who had no equipment. Then he would have to pay, naturally, \$1,207. But let's just suppose that he had been a horse farmer. He could spare at least a team of horses if he bought this small tractor, and he wouldn't need his horse plow, he wouldn't need his horse cultivator, and he wouldn't need his disk harrow. So he would say, "I will see what I can get for that in a trade-in." I am just making an assumption, Mr. Chairman, that the dealer would be able to allow him \$250 for that. It might be considerably more; in some instances it might be less. But suppose the dealer did allow him \$250. He would then have a net balance to pay of \$957, and that balance, then, could be paid for in accordance with the usual credit terms over a period of two harvests.

Dr. ANDERSON. In other words, Mr. McCormick, his annual payments would be around \$400 to \$500.

Mr. McCORMICK. About \$475.

Dr. ANDERSON. And I take it from your testimony this morning that it is possible for an up and coming ambitious farmer who seeks to compete with mechanized farms in his neighborhood and in his crops to get access to the \$400 or \$500 and the equipment in the first year.

Mr. McCORMICK. Without any question in my mind, Mr. Anderson. In fact, a great deal of our equipment is sold and works out on the basis that the investment in that equipment will be returned in increased yield and increased income to him, and we must assume that that has been the case in hundreds of thousands of instances on the farm.

The VICE CHAIRMAN. Now, how do you know that his yield is greater? Have you statistics showing that the yield average is greater on a farm cultivated with machinery as distinct from horses?

Mr. McCORMICK. There are figures, Mr. Chairman, some of which were submitted yesterday by the Department of Agriculture, indicating that in the case of the fully equipped farm, the mechanized farm or the tractor farm, the yields are increased over the horse farm. That won't maintain, naturally, in every case, but there is considerable evidence that there is an increased production on those farms in which machinery is used.

The VICE CHAIRMAN. Were those figures based on statistics gathered from a given farm cultivated by animals, and that same farm cultivated by machinery, or do you know?

Mr. McCORMICK. I don't know that. I don't know the basis on which these department figures were arrived at, but Mr. Johnson yesterday submitted figures showing an increase, I think in one case of 7 percent, and in another case of 15 percent in the case of a mechanized farm or the horse farm. You see, with tractor power you can make

operations more timely than you can with horsepower. You know the importance of that in planting and seeding and harvesting, and those things do tend toward an increased production.

EFFECT OF MECHANIZATION ON LABOR COSTS

The VICE CHAIRMAN. What effect upon labor costs on this 50- to 70-acre farm will result from the change to mechanized farming?

Mr. McCORMICK. Well, the assumption that we must make in that case—it is only an assumption, but I am making it because I believe it would be the typical case rather than the exception—is that a 50- to 70-acre farm was a family farm. In other words, a farm of that size, unless it was a very specialized truck farm or something of that nature, could most easily be handled by one family. In that case you would have an instance where the advantage to the farmer was a lessening of his hours of work and the arduousness of his labor, and an increase, or rather, let me say a decrease in the cost of his production along with an increase in his production of crop. In other words, in that case I would assume that you wouldn't have a displacement of labor. That is only an assumption, and I wouldn't say that there might not be some farms of that size which had a hired man who perhaps then wouldn't be necessary if you had this mechanized equipment.

The VICE CHAIRMAN. What is the difference between the element of obsolescence or wear-out in the two sorts of farming equipment?

Mr. McCORMICK. Well, we have to consider two things there. We have to consider, in the first place, machinery versus machinery—in other words, a horse tool versus a tractor tool. I don't believe there would be any difference in the obsolescence or depreciation there. In other words, a horse cultivator probably, I would think, would last as long as a tractor cultivator, although, due to the bearings, and wheels, and so forth, it might not. Then we have to consider the obsolescence, or the depreciation, if you choose to call it that, of the horse versus the tractor. That is a figure that I am not prepared to give you. That is a question I am not prepared to give you exact figures on, but I should say that the depreciation, the period of depreciation, of a tractor would be somewhat longer than what you have to figure on a horse. In other words, the expected life of a tractor would be longer than the working life of a horse.

Dr. ANDERSON. Mr. McCormick, that covers substantially the story with respect to the family-sized farm. You have been putting out, however, combines which have gone into the harvest fields, particularly into the prairie harvest fields, for a number of years. There undoubtedly, as these combines have met man competition, a number of harvest hands have been affected. What, in your judgment, has been the net effect of the introduction of harvest combines in the prairie areas?

Mr. McCORMICK. I should think that one might characterize the net effect, briefly, to sum it up, as one of stabilization of employment. If you remember, back in the days when the binder and the threshing rake were used you had the situation in which a large number of men were needed to shock the grain that came from the binder, and then you had the situation of the threshing crew wandering around the country, either in a ring among farmers, or a traveling commercial

crew, and that kind of operation was characterized especially in the western plains by a very distinct type of migratory labor. There was a large number of men who traveled from the Mexican—well, not quite from the Mexican border, but from Texas, through Oklahoma and Nebraska, and up to the Dakotas and Montana, and even Canada. Now, if anything has happened, I would say that in the first place the living conditions for the farm wife have been enormously improved, because she doesn't have to take care of this gang of men who crowded in on her and dirtied the kitchen up and bothered the life out of her, and, secondly, that the work of the harvest now is stabilized within the individual farm, or a very small group of neighbors, one of whom may rent the machine from his other neighbor, or borrow it in exchange for other work. So I think we could characterize it by the increase of stability.

The VICE CHAIRMAN. Wasn't the question as to what effect it had on labor?

Mr. McCORMICK. The general stabilizing of labor, I would say, Mr. Chairman, and that is borne out by the peak figures as shown in Dr. Johnson's chart of labor on a 320-acre central Kansas farm, in which is it very obvious that the harvest peaks involve a great number of men who just have that amount of work, and then have to drift on.

The VICE CHAIRMAN. Yes, but the effect, isn't it, is to eliminate the jobs of these migratory laborers and make it possible for each community to take care of its own harvest?

Mr. McCORMICK. That is it exactly, and, of course—

Dr. ANDERSON (interposing). What happens to these migrants or transient laborers who found their sustenance in the harvest fields, and were able in some way to eke out a year-round existence as a result of what they got there, and what they could pick up elsewhere?

Mr. McCORMICK. I am not able to answer that question in detail, Dr. Anderson. I imagine those—it is not only imagination—men have had to find more regular employment in some locality rather than wandering; but aren't we safe in making it—or taking the position that if any form of labor has to be obviated, the floating or migratory form is possibly socially the best one?

Dr. ANDERSON. In other words, you are assuming that if labor is to be displaced, it had better be the floater than the person who has a tie in the land?

Mr. McCORMICK. That is it exactly.

Dr. KREPS. Is that stability or stabilization of employment taking place in other than wheat farming? Is the effect, for example, in fruit and vegetable growing in California of the introduction of the machine, of the same order?

Mr. McCORMICK. Well, I am not really prepared to answer that question with a great deal of confidence. However, I think it is true that in any situation in which you have peak demands for labor, the use of a machine on the individual farm would tend to stabilize labor, at the same time displaces that migratory laborer.

Dr. KREPS. Now, mechanization is used, say, for plowing operations and cultivating operations, and your peak laborer is engaged in picking, such as is frequently the case in fruit farming. Then would it not be true that you would use fewer laborers in the seasons

in which you would do plowing and cultivating, seasons which are slack, in which labor is slack anyhow, and that on the whole, the peak labor which is used for picking would not be eliminated.

Mr. McCORMICK. That is true. In other words, in certain operations, there are bottlenecks, and until there is something that can be done about those, they still remain.

Dr. KREPS. That is what I was trying to bring out. You are quite right. In the Kansas wheat area, the mechanization has served to get at the peak of the harvesting demand.

Mr. McCORMICK. Yes, and level it off.

Dr. KREPS. Yes, it leveled it off. But there are an array of other products in which that may not be true.

Mr. McCORMICK. No, because you have not been able to eliminate that particular operation.

The VICE CHAIRMAN. Well, you just cut the top off, don't you? You just eliminate these people who travel around getting employment?

Mr. McCORMICK. That is right, Mr. Chairman.

The VICE CHAIRMAN. And what became of them we just don't know.

Mr. McCORMICK. Well, that is the question which Dr. Anderson raised, and that is one of the social questions we all have to find some answer to.

PROSPECT OF FURTHER TECHNOLOGICAL CHANGE

Dr. ANDERSON. I have one more question I want to ask. We have asked it successively in these hearings of witnesses on the topic of technology and its impact.

Mr. McCormick, in the field of agriculture, do you know of any impeding major technological changes, such as, for example, the cotton picker and others that might occur to you, in your laboratories or in the process of development in the area, that will have an effect, and what effect will they have, on agricultural labor and the development of American agriculture?

Mr. McCORMICK. Well, Dr. Anderson, if I may have your permission, I could best cover that, I believe, by reading a portion that I omitted this morning, if I have the chairman's consent to that?

The VICE CHAIRMAN. Yes, sir.

Mr. McCORMICK. At the present time, machinery is available for handling all processes in the production of hay, small grain and some row crops. On the other hand, the production of cotton, tobacco, and vegetables can only be handled in part by machinery. It might be of interest to enumerate some of the major farm operations for which so far no satisfactory commercial machines have been developed.

A crop which badly needs mechanical assistance at present is the sugar beet crop. What is required is a machine that will pull the beet out of the ground, cut off the green top without removing a wasteful amount of the beet itself, and load the beet into a truck. Fairly successful machines can be built, but none now exists which can justify itself on a medium or small-sized farm from an investment standpoint.

Secondly, there is now a demand for a corn combine, a machine to do for corn harvesting what the combine does for wheat; that is,

to pick, husk, and shell the corn in one continuous operation. The problem is not yet solved. It is not a mechanical problem, but one of the moisture content of the corn. The corn must in some way be dehydrated after shelling so that it may be safely stored in bins.

Thirdly, similarly, there is a large demand for a sugarcane harvester. Cane presents a problem because it varies greatly in size and requires three operations by a commercially successful machine. The cane stalk must be cut as close as possible to the ground, the leaves must be stripped from it, and the two upper joints of the stalk, which have no sugar content, must be cut off. There is a great demand for this machine, but you might be interested to know that the problem has defied satisfactory solution so far as we are concerned for more than 35 years.

Now, it is a fact that several machines have been built for these purposes, but they are very large and bulky and expensive machines, and we have never come anywhere near finding a solution to that problem mechanically and what we think is a commercial product.

The VICE CHAIRMAN. Mr. McCormick, right on that point, we have now an arrangement under which we can cut the stalk close to the ground.

Mr. McCORMICK. In the sugarcane?

The VICE CHAIRMAN. Yes; by human beings.

Mr. McCORMICK. Yes; you mean with a knife?

The VICE CHAIRMAN. Yes. I mean, it is possible now to cut the stalk close to the ground.

Mr. McCORMICK. Correct.

The VICE CHAIRMAN. It is possible now to strip the leaves from the stalk. It is possible now to cut those two upper joints off.

Mr. McCORMICK. All by hand, you mean?

The VICE CHAIRMAN. Yes. But I say it is possible to do that thing.

Mr. McCORMICK. Yes.

The VICE CHAIRMAN. Now, being done by human beings with their hands—then we get a machine that does it. There is no job that we know of for those people to engage in who used to do stripping, cutting, that sort of thing. As I said this morning, I appreciate that we have got to go ahead with this business. There is no way to turn back that I can see. We cannot let those people starve, it is against the law to kill them, and if you killed them, why, it would shut down the use of the sugar and you would put the sugar fellow out of business. [Laughter.] This whole business is not a one-sided business, is it? I mean, it really has two sides to it.

Mr. McCORMICK. Of course it does.

The VICE CHAIRMAN. How much real progress is there in a trend that is displacing a human being with a machine and putting him out on the road? I hope you will understand that I am not criticizing this trend, but I am not unmindful that it obtains.

Mr. McCORMICK. I do. What you are saying is that any advance in any technology creates new problems that didn't exist before, it solves some and creates others.

The VICE CHAIRMAN. When we have accumulated such a surplus of unemployed people, I have had a serious question as to whether or not the government ought to continue to offer a premium in the nature of a patent.

Mr. McCORMICK. In the nature of what?

The VICE CHAIRMAN. A patent. I have had a question in my mind, when you accumulate this surplus of unemployed people and with such an inefficiency on the part of the generation of which I am a part to deal with these big problems which we are creating by our unusual or rapid advancement in the supplanting of human beings by machines, whether or not it is a sound policy to continue to offer a premium, a bid, for more inventions or more machines and put more people out of business. This is something we have got to face. Of course, a patent is not a natural right; it is a thing given by government, and the government is now bidding 17 years of the right of monopolistic use to anybody who will invent a machine that will add some more idle people to what we have already got. I know that is not the whole picture. I am just stating one side of it. The other side we all understand. But it is there, and I wish these gentlemen who are digging up testimony would bring us 2 or 3 people who are smart enough to handle it.

Mr. McCORMICK. I would like to find them.

The VICE CHAIRMAN. Yes; I would, too. You are making an interesting and helpful witness.

Dr. ANDERSON. There is one other feature of the new technology that has come to our attention. I wonder if you would comment on such a thing as this rotary tillage that we have been seeing so much about in the papers in recent days. Does it offer something for the future which will increasingly displace the use of man-power on the farm?

Mr. McCORMICK. By rotary tillage, do you mean that type of plow which may have a share but up above you have a revolving member which breaks up the soil?

Dr. ANDERSON. That is right.

Mr. McCORMICK. I haven't see the recent press notices on that or the stories on it, but that is not a new idea, as you know. That has been experimented with for a great many years. We have made some tests of it. I think there were quite extensive tests made in Iowa on that kind of implement. The point of it I think probably would be that in certain soils it would do a very good job of pulverization of the soil, we might not have to do any disking after such a plow; on the other hand, in some soils it probably would do too good a job of pulverizing. I wouldn't care to comment on it because I haven't read just what you are referring to, but if I may say so, I am doubtful that it would be a thing in the nature of a great revolution. It might be a moderate change in farm methods.

Dr. ANDERSON. And it is your contention that new technologies or impending ones have an introductory phase sufficiently long for adjustments to be made to meet them as they arise, as they become widespread?

Mr. McCORMICK. I believe that to be true in almost every case. You take this case of the cotton picker. I was going to refer to that in a moment. That is a similar thing, and the development of these machines is a very long process, as you know. It takes years of experiment. We have been working on the cotton picker for a great many years, and the sugarcane harvester, and many other things that we haven't found the solution to. Then, furthermore, the introduction and use of those machines is not just over night, on the whole. I remember when we came out in 1924 with the Farmall

type of tractor, a thing that has been as revolutionary in its effect on farm mechanization as almost anything, the farmers were slow to take hold of it. It was a funny looking thing to them, it wasn't like the conventional tractor. I believe that is the general case, as you mentioned.

Dr. ANDERSON. When Rust was planning the introduction of the cotton picker, scientific journals and popular journals mentioned that Rust had developed a contract which he proposed to enter into with purchasers or users of the cotton picker, in which he took account of this very problem. He realized the probability of the displacement on a large scale of workers, and therefore would attempt to ameliorate this in his contract which introduced the Rust cotton picker by certain things that would be to the advantage of the labor there displaced. Do you know of any practical attempts on the part of either implement makers or others to meet this problem in some fashion?

Mr. McCORMICK. I do not. I do not know of any such action as you speak of.

The VICE CHAIRMAN. Well, you couldn't get a contract that would stand up through any long period of time under which somebody would agree just to hand over part of his property to take care of somebody who was sitting on the fence.

Dr. ANDERSON. That is perhaps a weakness of the Rust contract.

Mr. McCORMICK. If I might read this section, it might bring out that point.

For many years there has been a demand for a mechanical cotton picker. This was especially true during the 1920 decade when labor was fully employed and foreign migrant labor was frequently imported to pick cotton. Several machines now exist which will get the cotton off the plants in a fairly satisfactory manner provided the conditions are favorable.

Our company's experimental work on cotton pickers has extended over approximately 30 years, but we are not yet really satisfied with the results and have never offered a machine for sale. The necessity of leaving the cotton plant uninjured for further growth and subsequent pickings, and the great irregularities in the size of the cotton plants present difficult problems. Cotton picked with present experimental machines is usually graded down because of the presence of leaf stains and more or less trash, and the grading down means a lower price and less possibility of saving.

A special study of mechanical cotton pickers was made in 1937 by R. L. Horne and E. G. McKibben under the direction of the Works Progress Administration. The authors state, page 18:

"Even though a mechanically successful and economically feasible cotton picker may be near at hand, its spread will probably be gradual rather than sudden. This view is strengthened by the history of the introduction of other agricultural machines. Rapid mechanization has occurred only where the financial rewards have been high or labor shortage acute. Therefore, as long as there is an abundance of cotton pickers willing to pick cotton for 75 cents to \$1 per 100 pounds, and as long as other prices maintain their present alignment, the mechanical picker cannot be expected to take the Cotton Belt by storm."

I concur in this view that if and when the cotton picker comes into commercial production, its use and spread will probably be gradual.

PROSPECT FOR INCREASED FARM EMPLOYMENT

Mr. O'CONNELL. Mr. McCormick, referring generally to the unemployment problems of the country, would it be fair to conclude from your statement that in your judgment the agricultural industry or that line of endeavor affords little hope for absorbing any substan-

tial number of the unemployed in the country today, at even assuming a much higher level of income?

Mr. McCORMICK. When you say the agricultural industry you mean the farm?

Mr. O'CONNELL. I mean the farm, of course.

Mr. McCORMICK. I am afraid I am not competent to give a judgment on that.

Mr. O'CONNELL. The thing that caused me to believe that was your general belief was that you quoted with approval that statement from Dr. Ezekiel in which he suggested that the more fundamental problem is how to put back to work the city people who are not now working and who are ready to work.

Mr. McCORMICK. Right.

Mr. O'CONNELL. It occurred to me that even assuming no more rapid technological advance is taking place at the present time, with the present people on the farm, the farmers would probably be able to produce enough of the products that they are presently engaged in producing to take care of those persons even assuming much more mass purchasing power than exists today. I thought that was the general tenor of your remarks. Maybe I am wrong.

Mr. McCORMICK. Yes; that is the point that we heard quite a little discussion on yesterday, whether a pick-up in industrial centers will mean a large or a small or a negative pick-up in farm employment. Now, I am not prepared, I am not expert enough, to give a really valid opinion on that, but my feeling is along the lines stated there, that industrial pickup, increased employment in the cities, should mean some improvement in the farm situation, and to my mind that, plus the other thing that was talked about yesterday, namely, the introduction of new farm products as time goes on, are two of the most hopeful possibilities for reemployment on the farm, or increasing employment.

Mr. O'CONNELL. That rather interested me because we have had witnesses here who in other fields took something of the same position. For instance, the representative of the white-collar workers is of the belief that that particular line of endeavor is already very overcrowded and that there will be little or no opportunity to absorb any of the unemployed in that area. The farmers take the same view. Other groups seem, on the one hand, to feel confident that something is going to happen to take up the slack of the unemployed, but insofar as their particular line of endeavor is concerned their position is, "Let George do it because we can't." If that becomes general it leaves us rather hanging in midair as far as any place, any specific place, to absorb the people who are unemployed. It isn't very helpful to the unemployed to have someone say that technological advance ultimately increases productivity and therefore more work and all that sort of thing, when you have accompanying that fact what is assumed to be a fact, that there are 10,000,000 people out of work.

Mr. McCORMICK. Well, those, of course, are very difficult problems to talk about, and one cannot safely make predictions. On the other hand, I have the feeling that it is just as unsafe to take a given set of conditions and say that that set of conditions is going to continue forever. In other words, there might be the introduction of this thing new or that new thing which is quite unforeseen today. You know what I mean.

Mr. O'CONNELL. Oh, of course, but it is somewhat nebulous when the only alternative is to say that something about which we know nothing is going to happen.

Mr. McCORMICK. That is correct.

Mr. O'CONNELL. The most concrete thing about the condition is 10,000,000 or 12,000,000,000 people out of work.

Mr. McCORMICK. It is necessarily nebulous, as the same kind of thing in history has been nebulous many times. There have been times when the future looked just as dark as it may at the moment.

Mr. O'CONNELL. There may have been.

Mr. McCORMICK. I am saying that I can't, and I don't believe anybody can see clearly into the future, yet, on the other hand, I personally wouldn't dare take the position that something couldn't happen that we are not able to see at the moment. I do say that in the meantime we have to do temporary things to clear the situation.

Mr. O'CONNELL. It seems to me perfectly obvious that as between hoping for something to happen and trying to make something happen, the balance is in favor of the latter.

The VICE CHAIRMAN. I think this kind of business is a whole lot more important than about these machinery improvements you have made, because we all know about that. Anybody going down the road can see machinery has been improved, and it is interesting too, but we are trying to find out something about what we are going to do about it, not what you did about your job, but what we are going to do about it. That is what this gets down to. If we could get rid of about 90 percent of these words and get down to business—I think, though, we have some other kind of a doctor coming on who knows something about this.

Mr. PIKE. I have one before you go, Mr. McCormick, and I am afraid it is impractical, too, but we heard yesterday about the wages of farm hands. I was really pleased to know that somebody was hiring people at \$1 a day to work on the farm. They are not in my area. But it sounded pretty bad when you got to the all-yearly wages of a good deal less than \$1 a day all over the country. So you not only have the problem of the unemployed labor and the partially employed labor, but as nearly as I could read it the fully employed laborer had quite a little problem. He didn't have any leisure and he didn't have much income. The steel worker in 30 days could earn more than the farm worker in a year, according to the figures that were presented, and I just wondered if you approached, as part of the solution, the same thing that we have done in industrial lines, and if Congress, in its wisdom, passed a minimum wages-and-hours law for farm workers, giving them something like the same minimum wage that industrial workers have, it would, without question, have a great upsetting effect in tremendous areas. It would change some cost figures enormously.

Mr. McCORMICK. Yes.

Mr. PIKE. Well now, it wouldn't change the cost figures on a family farm much of anything. The thing I wanted to ask you was, if something like that did happen and there aren't enough solutions around so that you can afford to throw away anything that offers even the shadow of one, you probably would increase mechanization further on farms which had part-time labor, almost surely, if you

really had to pay a decent-day's wages. And you would probably have quite an effect on further mechanization in what we may call corporate farming, very large-scale farming if you, say, double the wage rate. The incentive to mechanization would be much greater, of course.

Mr. McCORMICK. Yes.

Mr. PIKE. You have a further displacement of substantial size of these partially employed, and I should think perhaps of some fully employed who still end up with \$126 a year in the Mississippi Delta, but it is a real question whether that would be a loss, whether that would end up in a loss or a gain. It is a sort of inchoate thing in my mind; I didn't mean to say I am for it. That is one of the things that has to be looked at. Farm wages, even for the fellow who is working all the time, are way out of line with industrial wages. I believe they are further out of line than the so-called parity prices that we saw yesterday between farm products and industrial products.

The VICE CHAIRMAN. But it doesn't seem to me, as a plain farmer, that there ought to be much difficulty about that. Whenever your labor cost gets higher than you can afford to pay, as against the job where the man was you get a machine. That is all there is to it, and you take these factories—they have organized labor, they sell their labor; but you take a producer of an exportable agricultural commodity and he sells to the highest bidder in the world market, and to him the domestic market is the lowest market, because he has to sell his commodity in the domestic market at prices much lower than the world market, with the cost of transportation from the domestic market over the world. You people can take your surplus up to Canada and sell it at a less price.

Mr. McCORMICK. We don't do that.

The VICE CHAIRMAN. I know you don't. I just said you could.

EMPLOYMENT IN FARM MACHINERY INDUSTRY

Dr. LUBIN. Mr. McCormick, this is a little bit aside from the subject of this testimony, but in view of the fact that you are here and we are interested not only in agricultural employment but in industrial employment, I wonder if we could get 2 or 3 minutes of your time to discuss some of the elements of employment in your own industry.

How many people do you employ, roughly?

Mr. McCORMICK. Well, that varies, of course, Mr. Commissioner. I should say, roughly, around 50,000 at the present time.

Dr. LUBIN. And has the trend over the past several years been upward or downward?

Mr. McCORMICK. In our plant it has been upward. In '37 we employed considerably more people than we did in 1929.

Dr. LUBIN. You people have the problem of technological displacement in your plant, I take it?

Mr. McCORMICK. Right.

Dr. LUBIN. Do you have any policy relative to installation of machinery to ease displacement?

Mr. McCORMICK. I think I would have to answer that question in two ways. If it were proportionately a small number of men

involved, the situation would be handled more or less in just the regular ways, having regard to seniority arrangements and agreements, and it is not a simple problem. I mean it isn't simply to analyze. It isn't just as if, let's say, a new machine was installed and one man was put out of work and then the question was, Would he be on the street or wouldn't he? It isn't as simple as that. That man who was displaced by the machine, let us say, has a given seniority standing in that plant. Therefore, if he had a long service, he would take the place of a man with a shorter service.

Now, then, that process would go on down the usual line until you came to the last man in that chain. Now, what happened to the last man would depend—and here is the complicating factor—on the nature of our employment at that time. If our employment was even slightly going up, and I should say under any even keel of employment, that man would not be thrown out of work. If employment was decreasing at the time, then he, along unfortunately with others, would be laid off for the time being. So in that sense it is not a simple problem to answer.

Now, suppose, to take a very extreme case, a very major thing should occur that I can't conceive of occurring, but should it, that a whole department, let's say, or a whole plant, due to some technological change, was affected in such a way that employment was greatly decreased. I could cite to you what we did in a similar case, not for that but because we were moving the manufacture of a given number of machines from one plant to another. In a case like that the men who were of pensionable age would be pensioned. We have had a pension plan for some 32 years.

The men who were nearly of pensionable age we would give a pension. The rest of the men we would try to employ in some neighboring plant of ours. And then, down to a service of perhaps 3 to 5 years, we would do something in the neighborhood of termination wage or something of that nature for them.

I am just speaking of a very extreme case, to illustrate the principle, and I have never seen that happen in our company.

Dr. LUBIN. I take it from what you say, then, that changes in technology in your industry are not radical or revolutionary in the sense that something comes along and displaces a whole series of men.

Mr. McCORMICK. That is correct.

Dr. LUBIN. A gradual change is taking place from day to day or when you change a model or something of that sort.

Mr. McCORMICK. That is correct.

Dr. LUBIN. And consequently this technological shift is taking place every day in the work.

Mr. McCORMICK. That is correct.

Dr. LUBIN. And it is your policy to provide for these people, either through normal turn-over or through expansion periods, or when you come to an acute crisis, through giving a man a pension before he is entitled to it, or a dismissal wage.

Dr. ANDERSON. Mr. Chairman, we have another witness this afternoon that I would like to interject here.

The VICE CHAIRMAN. Bring him on.

(The witness, Mr. McCormick, was excused.)

Dr. ANDERSON. Mr. Chairman, the final witness in this series on the discussion of technology and its impact on agriculture is Dr. Paul Taylor, professor of economics, University of California, Berkeley, Calif. Dr. Taylor hasn't been before the committee and should be sworn.

The VICE CHAIRMAN. Do you solemnly swear the testimony you are about to give shall be the truth, the whole truth, and nothing but the truth, so help you God?

Dr. TAYLOR. I do.

**TESTIMONY OF DR. PAUL TAYLOR, PROFESSOR OF ECONOMICS,
UNIVERSITY OF CALIFORNIA, BERKELEY, CALIF.**

Colonel CHANTLAND. Dr. Taylor, before you start, may I ask a question?

Dr. ANDERSON. May I qualify him first?

Dr. Taylor, how long have you been engaged in the study of agricultural economics?

Dr. TAYLOR. Something over 12 years, Dr. Anderson, under various auspices—my own institution, the University of California; the Social Science Research Council of New York; and with the California Emergency Relief Administration, as field director of the Division of Rural Rehabilitation; regional labor adviser of the Resettlement Administration; and consultant to the Social Security Board. I am professor of economics at the University of California.

Dr. ANDERSON. Have you published in this field that you are going to give testimony on?

Dr. TAYLOR. I have published numerous materials, Government reports, articles, and several books.

Colonel CHANTLAND. Before you start with your paper, may I ask a question? I see you are from California where the trek ended, and I notice by the papers this morning that this committee was presumed to have gotten into a discussion of Steinbeck's book yesterday. I wonder if you could give us your judgment as to the truth of the picture of the conditions there discussed?

The VICE CHAIRMAN. Oh, now wait a minute! Do you want him to jump on the book as a competitor?

Colonel CHANTLAND. Oh, I don't think they are competitors.

The VICE CHAIRMAN. But I mean, would you have any embarrassment in doing that?

Dr. TAYLOR. It would be very nice if I could be a competitor. His sales have been very fine.

The VICE CHAIRMAN. But I mean, seriously now, do you want to discuss the book or do you just want to give your testimony?

Dr. TAYLOR. Well, Congressman, perhaps I can put it this way: It is in a sense embarrassing to ask a social scientist to venture into the fields of literary criticism, and in that sense I am not at all competent to answer. But if, on the other hand—

The VICE CHAIRMAN. We might have some criticism of the social scientist.

Dr. TAYLOR. The purport of the question is this: Have you a serious, even critical, problem among migratory agricultural workers in California? I can answer that question unhesitatingly. Yes; we have.

I brought with me a photograph furnished by the Bureau of Agricultural Economics, which your committee may wish to examine.

Dr. ANDERSON. What is the photograph?

Dr. TAYLOR. That photograph was taken only a month ago and shows migratory agricultural laborers, mostly families, encamped behind the levees at Sacramento, our State capital. I think you can see from that photograph the conditions of these laborers in our State.

Before leaving the question, however, I should like to say this: That many people believe we have a problem in California which is peculiar to our State. I think it quite true that we have the problem in its most acute and most dramatic aspects. I hope before my testimony is completed, however, that I will have brought you to a realization of the fact that in varying forms and degrees, similar problems are developing in a number of parts of our country and that we have the problem only in its most acute form.

The VICE CHAIRMAN. I think the entire committee has recognized that fact, Doctor. I believe you wouldn't have to take much time to convince us of that fact. You say it is most prevalent, but wherever there are any migratory laborers, they follow along these seasonal activities, you have similar situations to that?

Dr. TAYLOR. Yes.

The VICE CHAIRMAN. I think the committee is convinced of that fact.

Dr. TAYLOR. I am glad.

Dr. ANDERSON. Do you want to proceed with your testimony?

Dr. TAYLOR. Shall I proceed with my formal statement?

Dr. ANDERSON. Yes.

EFFECTS OF FARM MECHANIZATION

Dr. TAYLOR. The effects of machinery on agriculture which are beneficial are well known. The saving of arduous labor, the cheapening of costs of production, and, for many, the elevation of living standards on the land are so important that no reason exists to attack men or corporations simply because they manufacture or use agricultural machines. At the same time, the advance of machinery on the land is causing human and socio-economic problems which grow increasingly acute. Even in times of industrial prosperity these effects would be serious, for they permeate and alter in important respects the social and political structure of our Nation. In times of unemployment like the present, they are critical. Distress, severance of families from the land, reduction in status, and complete dislocation of farm people are appearing with striking similarities in widely separated areas. These effects and their import are the aspects I wish to discuss of those problems in agriculture which technological progress creates.

Ample statistics and other data on the increasing use of agricultural machinery, and the prospect that this will continue rapidly to spread already have been presented to your committee. I should like, as my contribution to your deliberations, to describe the social patterns which result, directing your attention, first, to the Cotton Belt, then, successively, to the Wheat Belt, the Corn Belt, and to the fruit and vegetable industry.

The landscape and towns of the western Cotton Belt today show clearly the effects of spreading displacement. We had believed that these would not appear until the manufacture of mechanical cotton pickers in commercial quantities. However, displacement is occurring now over large areas because of introduction of all-purpose tractors and auxiliary machinery. In west Texas, the Black Wax Prairie, the Panhandle, and the southwest quarter of Oklahoma, consolidation of cotton farms and displacement of substantial tenant farmers is proceeding rapidly. Landlords replace their tenants with tractors and hired laborers—sometimes 1, sometimes 6 or 8 or 10 laborers, when their holdings are large. Tenants with foresight and sufficient resources buy tractors, rent a second farm, operate them both—and another white American farm family has been cut from the land. Farmers not protected by ownership or strong family ties to the land are starkly fearful that their turn to go may be next.

Towns are crowded with the displaced. The local W. P. A. and relief rolls are loaded with them, a stream of distressed humanity forms and hopefully seeks outlet to the West, in Arizona and California. Empty houses of families who used to make their living from the land strew the landscape, windows are boarded, and cultivated fields close.

Letters from rural folk deeply troubled by what they see occurring appear in the Dallas Farm News, especially around the turn of the year when old leases expire and new arrangements for the coming year are made. The following are recent examples:

From Henderson County, Tex., December 1939:

I ask the editor kindly to publish the following copy of a petition. I ask every county in the state to send similar petitions to their Congressmen before Congress meets in January. It is for the purpose of asking some protection for the one-team and two-team farmers of Texas.

Do you love your neighbor? Something must be done. We, the undersigned, are opposed to a few men renting the whole country in order to get the government checks and the full cotton acreage the little farmer had and rerent the same house back to him. The little farmer has to then sign up for WPA work or relief. One man told me he was renting over 400 acres and nearly 500 acres of land, which deprive 15 one-team renters.

From Tishomingo, Okla., March 1940:

. . . the land hog is all-powerful. He may buy a tractor and get possession of all the land in a community and, with a little hired help, farm all the land and thereby drive all his neighbors off the land to starve—just for his own private gains.

From Crockett, Tex., February 1940:

The big landowner does wrong in discharging his tenants and working his land with hired labor, but since that is the only way he can get a fair compensation he can't be blamed. This situation is causing more people to be without work than anything else.

The ground for these popular fears is confirmed by experts. Professors Bonnen and Magee state in the Journal of Farm Economics for August 1938, that within little more than a decade, by introduction of tractors and four-row tillage equipment on cotton farms on the high plains, "the amount of cropland that can be handled by a farm family has increased * * * from approximately 100 to approximately 450 acres."

This process has some advantage for the one in four who may survive as a farm operator, but the other three face alternatives,

"none of which," say those Texas authorities, "are particularly promising."

In the first place, they may migrate to less productive land in lower rainfall zones on the western fringe of the area or in older areas to the east. Secondly, they may find their way into other occupations, in most cases as laborers. Thirdly, they may remain in the area as agricultural laborers with small chance for employment except during the hoeing and harvesting seasons, and perhaps be forced to depend upon relief during a large part of the year. The latter alternative has been the one most frequently resorted to during the past 3 or 4 years.

What this opportunity to become an agricultural laborer means to those who have been farmers is told by Dr. C. H. Hamilton of the Texas Agricultural Experiment Station in a 1938 report.

The typical farm tenant in the High Plains or in the Blackland (Prairie) may be expected to earn a net farm income of from \$800 to \$1,000 annually, even with cotton prices as they are today. As either a common or an agricultural laborer the same tenant cannot expect to earn more than from \$250 to \$300.

A fourth alternative of the displaced—farmers, laborers, and small townfolk alike—is to take to the highways leading west.

The process which I am describing so briefly has contributing causes more complex than time permits me to explain, such as drought, depression, and phases of the agricultural and relief program. But the displacing effects of machinery on the cotton land are final, and they are not limited to areas of drought.

May I call your attention at this point to the first chart, which shows the origins of migrants to California.

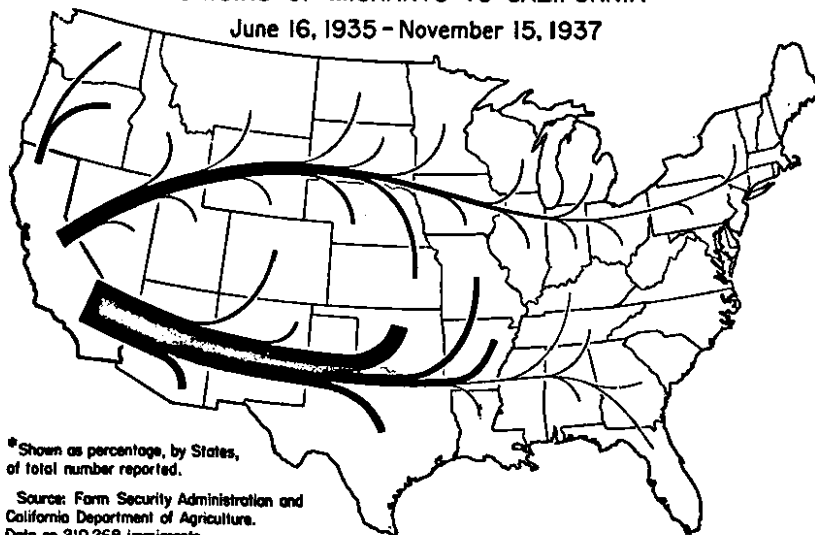

(The chart referred to was marked "Exhibit No. 2683" and appears below.)

EXHIBIT No. 2683

[Submitted by Dr. Paul Taylor]

ORIGINS OF MIGRANTS TO CALIFORNIA*

June 16, 1935 - November 15, 1937

*Shown as percentage, by States, of total number reported.

Source: Farm Security Administration and California Department of Agriculture. Data on 210,268 immigrants.

ORIGIN OF MIGRANTS TO THE WEST COAST

Dr. TAYLOR. This chart is, of course, not a measure of persons displaced by mechanization, for no such classification is possible in obtaining the data. However, it does show the origins of the people who have come to us in California seeking employment over about a 2-year period. The width of the line is proportioned to the percentage of the total influx to California that came from each particular State.

The VICE CHAIRMAN. Does that line bend back into the country from whence they came?

Dr. TAYLOR. It does, and by looking at the width of the line, you can approximate the proportion of the whole migration that came from that particular State.

The VICE CHAIRMAN. What I was asking is, you have three lines that bring these people into California?

Dr. TAYLOR. Yes.

The VICE CHAIRMAN. Do they move out of California?

Dr. TAYLOR. Out of California? No statistics are now available of the migration out of California.

The VICE CHAIRMAN. How do you accumulate these facts?

Dr. TAYLOR. These statistics are obtained by a count at the California border maintained by the California State Department of Agriculture.

The VICE CHAIRMAN. They do not maintain any count as they go out of California?

Dr. TAYLOR. The Bureau of Agricultural Economics a few months ago completed arrangements with the Arizona Department of Agriculture which will give us that back movement concerning which you inquire, Congressman, but at the present time that is not available. We know that there is a sizeable return migration. We know also the net deposit in California is heavy.

The VICE CHAIRMAN. These are what you call migratory workers, largely, these people.

Dr. TAYLOR. These people may very well find themselves in the kind of camp shown in the photograph at Sacramento. They are likely to be working in the southern San Joaquin Valley, migrating about, or seeking to settle themselves in one way or another.

The VICE CHAIRMAN. Those camps represent places where people who come into California, maybe who have been in California, who have no better place than those places in which to stay. That is all there is about it.

Dr. TAYLOR. The kind of camp that is exhibited in the photograph?

The VICE CHAIRMAN. Yes.

Dr. TAYLOR. There is no other facility available. The Farm Security Administration, you understand, Congressman, has placed a chain of camps through California to which many of these people come, and those camps have been very effective in eliminating the kind of condition that still prevails in Sacramento.

The VICE CHAIRMAN. To give the same person who is here a better place to live.

Dr. TAYLOR. To give the same kind of person who is shown in those tents and trailers a better place to live as he follows the crops.

There are other projects of the Farm Security Administration which endeavor to provide a better place. There are some of those projects in California and Arizona.

The VICE CHAIRMAN. What is the type of those?

Dr. TAYLOR. The project is of two types. Both are based upon decent housing. One type provides a small plot of ground around the house on which a garden may be cultivated. The other type provides what is called a cooperative part-time farm, in which approximately, it is believed, the rental paid for a decent house can be earned. The remainder of the income of the migratory labor family living in such a project is expected to be derived from seasonal employment in crops in California.

The VICE CHAIRMAN. In the meantime the difference is being taken care of in some way from the treasury of some governmental agency.

Dr. TAYLOR. That is very likely to be true among those in the lower income groups. There are of course some who will keep off relief.

The VICE CHAIRMAN. But do these houses that are put up bring a rental that will take care of the cost of production and construction and maintenance?

Dr. TAYLOR. I think, Congressman, that the Farm Security Administration could furnish you figures on that. I am sure that that is the intention, that the costs shall be kept low by extensive construction, and that the rental shall be such as can be paid by these people.

The VICE CHAIRMAN. Yes. I beg your pardon for leading you into that field, because it is a little aside from what you are discussing.

Dr. TAYLOR. Not at all, Congressman. I don't mind the questions in any way.

Colonel CHANTLAND. May I ask if there is any other project that tends to more permanency?

Dr. TAYLOR. Yes, Colonel; I planned to discuss that a little later, if that is agreeable, but I hope that question will recur. I don't know whether time is going to permit. I should like very much to answer that question. I would prefer to do so a little later.

May I invite your attention to the next chart, which shows origins of migrants to Oregon.

(The chart referred to was marked "Exhibit No. 2684" and appears on p. 17046.)

Dr. TAYLOR. This chart is constructed in similar fashion. The base of the data is somewhat different. It is based upon something over 5,000 rural immigrant families studied by the Oregon State Agricultural College. You may again compare the breadth of these lines showing origins from the different States. You cannot compare the breadth of these lines with the breadth of those on the preceding chart. In other words, the volume of migration to California is very much larger than the migration to Oregon. This shows the relative importance of different sources of origin of immigrants to Oregon.

The VICE CHAIRMAN. Doctor, what is the point about that? What lesson do we draw from the fact that people who are close by move in more numerous than people who are far away?

Dr. TAYLOR. My purpose in introducing the chart is twofold: First, to show that the problem is broad in respect to the destinations of those who are cut loose from the land; second, that the area of dis-

placement is broad. You will notice that the California migrants come mainly from Oklahoma, Texas, Arkansas, and Missouri. You will notice from the chart which I am now exhibiting that the Northern Great Plains States show up in much more important fashion. There is a whole belt of emigration which is not apparent as you look at the single chart.

The VICE CHAIRMAN. Do you think it is because there are better opportunities, relatively better opportunities, in that belt to which they are going, than would have been afforded if they had stopped closer to the point where they started moving from?

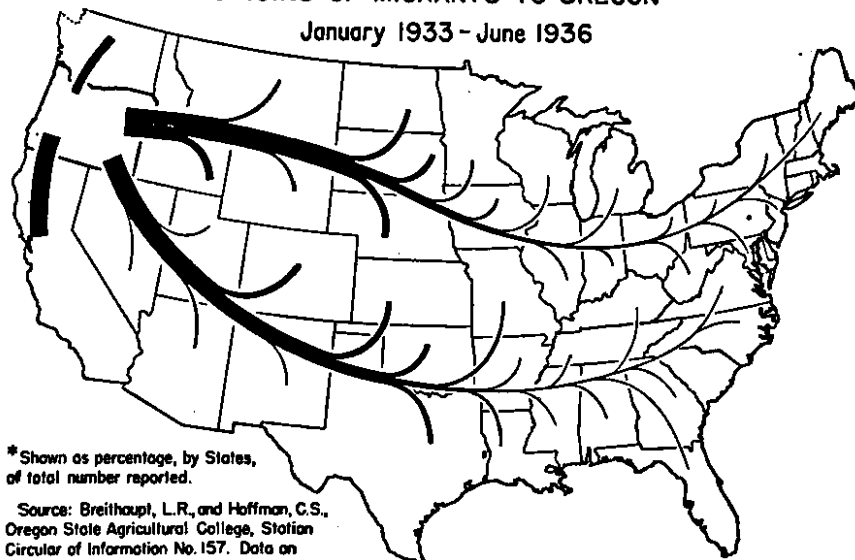

Dr. TAYLOR. I don't think that the reason they came to the west coast is primarily that opportunities are so good for them. I think the expelling forces are their principal reasons for leaving. I shall describe those in a moment.

EXHIBIT No. 2684

[Submitted by Dr. Paul Taylor]

ORIGINS OF MIGRANTS TO OREGON*

January 1933 - June 1936

* Shown as percentage, by States, of total number reported.

Source: Breithaupt, L.R., and Hoffman, C.S., Oregon State Agricultural College, Station Circular of Information No. 157. Data on 5,022 rural immigrant families.

CHART NO. 4

The third chart shows origins of migrants to Washington. You notice the source of emigrants lies still farther northward.

Dr. ANDERSON. That will be "Exhibit No. 2685."

(The chart referred to was marked "Exhibit No. 2685" and appears on p. 17047.)

SHARECROPPING ON COTTON PLANTATIONS

Dr. TAYLOR. Displacement of cotton farmers in the rich lands of Mississippi and Arkansas is beginning to be heavy. Sharecroppers, supplanted by machinery and wage laborers, are being swept from the plantations. They crowd the towns of the Delta and choke the slums of Memphis, Tenn. During cotton chopping in spring and picking season in the fall they are hauled daily in great trucks to work on plantations as far as 43 miles distant. The rest of the year

they remain largely unemployed, and a heavy burden on relief. They constitute a mobile labor reserve, supported at public expense in the winter, and by this fact make possible further mechanization and further displacement of sharecroppers.

It is the impact of these changes on the plantation system that produced the highway demonstrations in the Arkansas Delta and boot heel of Missouri in January 1939, and the eviction crisis in January of this year. From this area where both Negroes and whites are victims of technological progress, the displaced whites already have appeared in numbers as migratory workers in the cotton fields of Arizona and the pea fields of California.

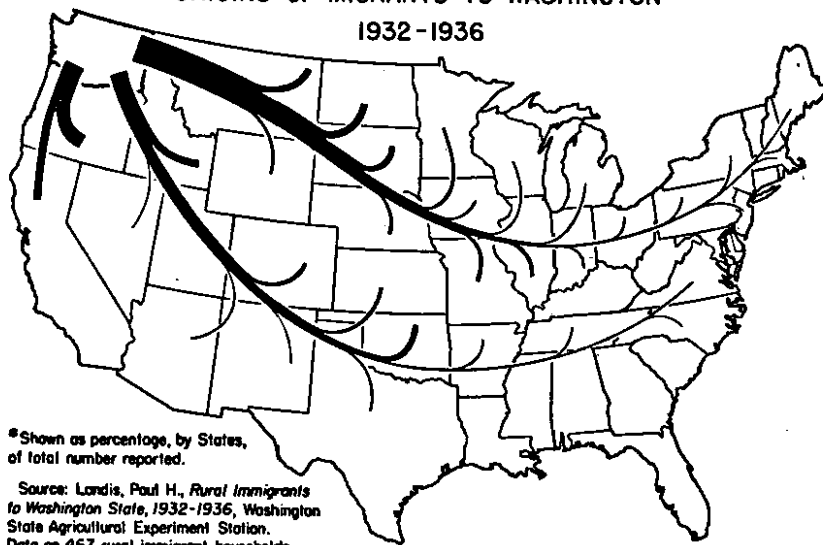

The displaced plantation Negroes who are not left on the land as wage laborers flock to towns. Some are seeking outlet in the industrial cities of the North. No tide of Negroes has yet started west. The advance of machinery in the Cotton Belt is irregular. It

EXHIBIT No. 2685

[Submitted by Dr. Paul Taylor]

ORIGINS OF MIGRANTS TO WASHINGTON*

1932-1936

spreads over delta and river bottom lands, and appears in spots where topography and other conditions are favorable, in Alabama, Georgia, and North Carolina. Behind this dislocation on the plantations is the economic pressure cited by a report of the Mississippi Delta Experiment Station which forecast in 1932 that "from 30 to 50 percent of present Delta farm labor must ultimately be replaced by machinery * * *." When plantations follow this program they are transformed into large industrialized farms. The starkest example of this change which I have personally encountered was told me by a planter who purchased 22 tractors and 13 four-row cultivators, let go 130 of his 160 sharecropper families, and retained only 30 for day labor.

In the Journal of Rural Sociology of September 1939, Prof. B. O. Williams, of Clemson Agricultural College, South Carolina, formally advances the proposition that—

The mechanization of agriculture in the South has already gone forward much further than is generally recognized * * * (It) will result in a disruption of the family-farm institution * * * It is probable that the owner-manager type of organization will come to prevail, changing the system of social organization from the family-farm type to the manager-labor type * * * The mechanization of Southern agriculture would result in either (1) a lowering of material living standards of large numbers of the farm population; or (2) the migration of large numbers of surplus and displaced laborers to other areas.

Mr. MAGINNIS. Mr. Chairman, may I ask a question at this time? Isn't the situation so far as the Cotton Belt is concerned due primarily to the low price of cotton as a result of the loss of the world markets in the last several years?

Dr. TAYLOR. Of course that is a very serious factor in cotton production. I don't think that is the major factor in the changes in the structure of production which I am describing.

Mr. MAGINNIS. You don't think that primarily that is the cause of most of the difficulty in the Cotton Belt in line with what has been written in the last several years about the necessity of changing production in the cotton States to other commodities?

Dr. TAYLOR. There is, of course, pressure for lowered costs and undoubtedly machinery is sought as one of the means of meeting that. I agree entirely with that. I think the use of the machinery, then, is the factor that cuts the pattern which I described.

Mr. MAGINNIS. In other words, the price of cotton in the last few years due to the loss of the world markets has forced to a large extent placement of machinery for more economical operation to avoid, if possible, the giving up of the raising of cotton.

Dr. TAYLOR. Possibly hastened it. I think there is always pressure for lower costs of production in a competitive market.

Dr. KREPS. Dr. Taylor, in that connection, if the price of cotton should rise appreciably, is it your feeling that the pace of mechanization would be retarded or is it likely to be accelerated in that farmers will have more funds in order to buy machinery?

Dr. TAYLOR. I think that a rise in the price would accelerate the process; as has been presented here by preceding witnesses, the purchases of machinery depend in part upon the income of the farmers.

The VICE CHAIRMAN. The reduction of the number of people to be found on the farm would seem due to the fact that we have lost a good deal of the world market regardless of how we lost it. It takes fewer people to raise 10,000,000 bales of cotton than 15,000,000.

Dr. TAYLOR. Certainly.

The VICE CHAIRMAN. Then you have this mechanization and that has something to do with it. I wonder if our governmental farm policy—are you going to discuss that—has anything to do with it.

Dr. TAYLOR. The agricultural adjustment program? I am going to make one recommendation with reference to it if I am permitted to at the conclusion of this statement.

The VICE CHAIRMAN. If you will be permitted to do it. [Laughter.]

Dr. ANDERSON. Dr. Taylor, I have before me the figures of the Department of Agriculture on the production of cotton, just to clear

this point under discussion. It is your contention that these major mechanical mechanization changes have taken place in the last few years?

Dr. TAYLOR. In the Cotton Belt that is true.

Dr. ANDERSON. If that is true, that it has occurred, say, since the depression, since 1932-33, except for the year '37, we have had a rather steady production of cotton, so that the production of cotton itself would not be a factor.

Dr. TAYLOR. I think there is no question that mechanization is an extremely important factor in displacing people in the Cotton Belt.

MECHANIZATION IN THE WHEAT BELT

Dr. TAYLOR. In the Wheat Belt the combine harvester and tractor have been displacing farmers, laborers, and many of the townfolk dependent upon them, during 15 years or more. In Oklahoma, so the State commissioner of labor reports, adoption of the combine harvester was already so general by 1932 that laborers furnished by State employment offices to wheat farmers dropped from 11,298 in 1921 to 165 in 1932, and that the machine had—

* * * completely reversed our harvest labor problems of finding and distributing an adequate supply of labor to that of preventing a surplus from coming into the state during the harvest season, as an oversupply of labor in any locality is almost as disastrous as a shortage and more so as far as the community in general is concerned.

A notable and significant, if extreme, instance of mechanization and labor displacement in Oklahoma wheat was drawn to my attention in 1937. In one of the northern wheat counties one man had purchased successively 100 quarter sections. He introduces machinery, leaves one tenant on each section, and displaces from one to three tenants.

The effects of the combine harvester on the inland empire wheat country of eastern Washington were described in 1932 by the United States Department of Commerce in a report of Edwin Bates. The report quotes first a leading wheat farmer:

We no longer raise wheat here in eastern Washington; we manufacture it. With large tractors, gang plows, seeders and combines for production and trucks for transportation to shipping points, we have virtually a factory system of production in which horses are rapidly passing out of the picture, and labor demands are decreasing. Under the new system this "wheat factory" can run 24 hours a day. Most of our operations can be carried on at night if necessary. In dispensing with work stock we reduce the number of men required. (*Commercial Survey of the Pacific Northwest*, p. 273.)

Bates, after traveling through the country, noting the abandoned farm homes and talking with townspeople, observed significantly that—

* * * there are two sides to this story. It is easy enough to reconcile the above statement of the wheat rancher with that of the implement dealer who estimates that every time he sells a tractor he drives at least 5 customers off the farms. The general merchant has frequently expressed it as follows: "This movement toward power farming is damaging every small town in this section of the State. Towns which had a good volume of business a few years ago are now very dull. There are fewer farms and less people on them. A few years ago we had a heavy seasonal labor movement into this section. The harvest hands would come in about the 15th of July and stay through the greater part of the summer. Now the harvesting season is much shorter, and there is a

smaller number of workers. Our sales of work shoes and work clothing of all kinds as well as foodstuffs have fallen off very heavily.

These divergent points of view, (continued the Department of Commerce report) "one from the wheat rancher with his eye fixed on lower costs of production, and the other from the retail merchant whose interest centers in an increasing population with an expanding volume of retail sales, are evidence of the changes which the technical revolution in grain production is working in the economic fabric of this area."

Between 1920 and 1930 in 7 counties of eastern Washington affected by this process of mechanization, the average size of farm increased 25 percent, the number of farms declined 19 percent, and the population fell 15 percent.

The effects of machinery on the wheat country of North Dakota today are described in the March 1940 issue of *Rural Sociology* by Professor J. M. Gillette of the University of North Dakota. In an article entitled "*Social-economic Submergence in a Plains State,*" he writes:

There has been and is thus being formed a self-perpetuating class of socio-economically submerged individuals in a wide region where it would least be expected.

* * * Rapid mechanization of farm production and farm processes and forced foreclosure of farm mortgages during recent years are the most important of the immediate and local factors. New types of rubber-tire tractors which propel new and larger plows, disks, harrows, seeders, harvesters and threshers, cultivators, sprayers, and so on, are rapidly transforming much farming into a highly sedentary mechanized and technically industrialized business. These machines are rapidly displacing agricultural labor of regular and seasonal kinds. I was repeatedly told that within 6 years the number of laborers required to harvest and thresh a crop of grain has been reduced from three or five to one. This means a displacement of 2 out of 3 or 4 out of 5 workers. It is also displacing many small farmers. Many men who operated a quarter or a half section a few years ago with horse power are now operating from twice to four or more times as much with tractor power, combines, and trucks. Two or three men in Bottineau County are operating 45 quarter sections of land, with a very few men as hired laborers * * *. This alone has caused the displacement of many small farmers and scores of laborers. It is a most serious situation for the young men and women on farms who are just coming to maturity. Farming no longer has power to absorb them; and after remaining idle parasites on the farmstead for a time, they float into towns and villages, marry, and join the Work Projects (sic) Administration forces. For them and the stranded agricultural laborers and farmers there is no longer a retreat in great cities to join the armies of manual and white collar workers; for those cities are filled with unemployed millions, and new recruits generally soon apply for relief and are then sent back to the Dakota counties from which they derived and where their legal residence is.

Professor Gillette estimates the probable future extent of this "submerged class" at from 5 percent in some counties to 15 or 20 percent in others.

The VICE CHAIRMAN. Doctor, I don't know how limited your time is. You are covering things that ought to go in the record, but they are matters with which the committee are very familiar. If you are not in a hurry and have plenty of time just go ahead and read, but if you are in a hurry just discuss the points you want to discuss with us.

Dr. TAYLOR. My time is at your disposal, Congressman.

The VICE CHAIRMAN. How much more have you?

Dr. TAYLOR. I have a half dozen pages.

The VICE CHAIRMAN. We want that all in the record for the permanent record, but the men who are sitting at this table are pretty familiar with that general picture. We are anxious that you get to

the point where you are going to make some suggestions. Pick out anything in there in particular that you would like to call attention to.

(The material omitted appears below):

CORN BELT MECHANIZATION

Dr. TAYLOR. The Corn Belt, like Wheat and Cotton Belts, is experiencing rapid mechanization, and with similar effects—displacement of laborers, expanding farms, displacement of farmers, replacement of tenants by wage laborers. As early as November 1937, Ray Murray, formerly Secretary of Agriculture of Iowa reported:

Despite the fact that we have this year in Iowa one of the biggest and best crops for a period of some 20 years, and despite the fact that these products have been selling for a price above the average for the past 5 years, and despite the known resumption of normal business conditions which are as favorable in Iowa as in any other part of the United States, we still find that thousands of Iowa people, farm-trained and farm-minded, are still without employment * * *. The greatest contributing factor in this distressing picture is the mechanization of Iowa farms with modern power machinery * * *. One man with a tractor behind which he can haul two disks and one harrow can thus do at less expense and less time the work that 3 men and 3 horse-drawn outfits would in an earlier day * * * many Iowa farms are now equipped with three- and four-row power-driven corn planters, and three- and four-row tractor-driven corn cultivators * * *. Other farm operations such as haying have been greatly simplified and hastened in their operations by such labor-saving equipment as side-delivery hay racks, mechanical hay stackers, sweep rakes, hay loaders, universal adoption of slings for unloading, and so forth. Modern manure spreaders, grain elevators, portable feed grinders and other such modern machinery have, also, contributed greatly to the ease and speed of farm operations, but have not been so successful in contributing toward the employment of men who make at least part of their living from such farm operation. We have seen the tractor-pulled binder shorten the harvest of our small grains by a considerable length of time and the introduction of small threshing machines have made a couple of weeks' job out of what used to be a month or two's work every year during the harvesting season * * *. The use of such machines eliminates the services of thousands of men who previously found work shocking the crop of oats, wheat, barley, and so forth * * * we could say roughly that the mechanical corn pickers in Iowa this year are replacing 15,000 to 20,000 men who formerly were employed at hand picking during this season of the year * * *. With the exception of Des Moines and Sioux City * * * in * * * our cities and villages, all the people who are not gainfully or continuously employed either as hired help or in their own establishments are men who depend to a greater or less degree on whole or part-time farm labor as their means of subsistence. With one single machine eliminating the jobs of over 15,000 of this class of people annually and with similar situations arising from the use of other power machinery, one can easily glimpse the position in which these people now find themselves.

From the Illinois Emergency Relief Administration come reports on April 29, 1938, that suddenly the spring farm-labor supply conferences held to help farmers needing laborers have turned into conferences to help laborers needing farm jobs which no longer exist. From county after county the reports came in—

From Calhoun County: As in other counties, power machinery is supplanting farm labor.

From Greene County: The supervisor of Kane Township gave us, before the meeting, some very interesting information as to what is occurring in his township. There are 10 farmers who are planning to plant 75 acres of corn each and intend to cultivate this crop without any help. There is one farmer who is tending 1,500 acres of land. He has 6 tractors and will hire only 6 or

7 men, when previously between 15 and 20 men were employed to tend this amount of land.

From Ogle County: One person who is a farmer on a large scale, stated that modern machinery has replaced to a large extent the need of farm hands and has tended to level off the cycle of farm work. He stated that in his own community of Polo there have been 70 tractors sold during this last year and that as a rough estimate each of these has displaced one farm worker.

From Vermillion County: The farm advisor and several members of the Farm Bureau pointed out that the displacement of the casual farm laborer was due in a large measure to the general use of power machinery and suggested that some program of public employment would have to be planned to absorb these permanently displaced agricultural workers.

From Peoria County: It is reported from the Jacksonville area that farmers are using their tractors day and night rather than hire additional labor.

Displacement by machinery in the Corn Belt is not limited to farm laborers. For farm operators, too, it is extinguishing the chance to make a living from the land. The chairman of the Iowa Farm Tenancy Committee stated in 1938:

A matter which received considerable discussion * * * is the operating of a number of farm units by one operator, thus displacing many farm homes. * * * Landlords naturally seek the greatest net income from their land regardless of possible destructive effects upon the social conditions of the country. Farmers with large sets of machinery bid up the rent to a point where a tenant family with little power equipment can no longer compete with large-scale operators.

In July 1939 Wallaces' Farmer and Iowa Homestead carried an article entitled, "Pushing Farm Families Off the Land." A State-wide questionnaire was sent out which asked, "How many farmers who were running farms in your school district 3 years ago have been squeezed out as a result of such expansion by big operators?" Drawing its conclusion, after eliminating the shiftless and incompetent from the count of the displaced, Wallaces' Farmer states:

If this sample is typical of the State it means that over 6 percent of Iowa's farm families have been pushed off their farms in the last 3 years.

On March 9, 1940, Wallaces' Farmer published a leading article called *Men Left Without Land*, which states after a field survey, "If those questioned are representative, there are around 2,000 new landless tenants this year." Displacement comes about under a number of circumstances, which are reflected in the attitudes of people toward them, says Arthur T. Thompson, author of the article:

I have listened to a lot of talk, trying to size up attitudes. Not much is said, I find, when a man goes back on his own place. This is still a free country; it's got to be expected. Nor is there much talk when a farm is sold to an enterprising chap who has been a good tenant, or when a father helps his son to buy a place. There is a little more stir when one man keeps increasing his string of tenant-operated farms, but this depends on how he treats the tenants. Sometimes, through his capital help, the multiple landlord actually helps the tenant to make more money.

It's when a landlord throws off a tenant and starts working the land with hired help, especially trailer-house migrants, that voices raise and you see anger on men's faces. Or when the farm is leased to a nearby owner-operator who, say the neighbors, already has "a God's plenty."

A friend of mine says this thing is going to end up in a farm-tenant's protective association or something of the sort, just like the share-croppers' union of the South. That seems a little extreme, yet I wouldn't be too sure if greedy owners and landlords keep reaching for more and more land. As I said at the beginning, I have been looking into the eyes of these landless men, and I see something there that is pretty sure to snap if they are pushed too far.

Dr. TAYLOR. I should like to call attention to the fact that displacement is moving rapidly into the Corn Belt, which has always

been regarded as one of the most stable sections of our American social and political life, that the same pattern of displacement of laborers and of small farmers which appears in the Cotton Belt is now occurring also in the Corn Belt. Tractors, smaller combines, a variety of machines, are accomplishing that. The farm laborers are hit with the utmost severity, and the smaller farmers are now feeling the pressure of displacement from machinery, and they are writing to Wallace's Farmer and Iowa Homestead the same kind of letters that the displaced tenants of Texas are writing to the Dallas Farm News.

The VICE CHAIRMAN. When you say the small farmer do you mean the tenant farmer or the owner of a small farm?

Dr. TAYLOR. I think mainly they are tenant farmers. They are the northern counterpart of what in Texas you call, I believe, the tenant farmers on thirds and fourths, substantial citizens with a substantial amount of property who find themselves deprived of an opportunity to make their living on the land.

Studies have been made by Wallace's Farmer and Iowa Homestead which indicate that for the last 3 or 4 years this has been progressing at the rate of something like 2,000 tenant farmers per annum.

Dr. ANDERSON. Dr. Taylor, is that a new phenomenon in the Corn Belt area?

Dr. TAYLOR. So far as I know, that has not appeared in the Corn Belt before. Certainly it has not been conspicuous, either to outside observers or to the people themselves in the Corn Belt.

The VICE CHAIRMAN. It has to follow, though, that wherever you have curtailment or reduction of acres, regardless of whether you have to do it or not, when you put in machines—I mean it just has to happen. Any field of production where you curtail your acres as a part of the program and then you put in machines, of course, you will have reduction of hours of work, but the tendency of those two things is bound to put somebody off the farm.

EXPANSION OF HOLDINGS AFTER MECHANIZATION

Dr. TAYLOR. When you put in the machinery, the tendency is to expand the size of your farm, in order to make use of the otherwise unused capacity of your machine.

The VICE CHAIRMAN. And when you have an agricultural program that requires a reduction in the number of acres that you used to have in a given crop, then that means a reduction, too. I don't mean to say that it isn't necessary to do it, but that is one of the consequences.

Dr. LUBIN. Mr. Taylor, just how does this happen—I was interested in your statement to the Judge just now, in other words, the farmer buys more land in order to make the machine pay its keep, or does he refuse to rent his land?

Dr. TAYLOR. In the Cotton Belt, it usually starts by a renting of more land. Take, for example, the tenant farmers in the plains of Texas. If they expand the size of the farm by placing machinery upon it, it throws 2 farmers together and 1 tenant leaves. Sometimes 2 tenants leave if the landlord moves in and operates directly

with hired labor. There is a loss of status of the tenant-farmers and replacement with someone of the hired-labor status.

Dr. LUBIN. And the same thing happens in Iowa? What form does it take?

Dr. TAYLOR. Well, I think the record will show that the pattern is strikingly similar in Iowa to what happens in Texas, that one man leases more land, or not infrequently, that a farmer with means buys another farm.

The VICE CHAIRMAN. I happen to come from Texas. If a man who owns maybe five or six hundred acres of land, who used to have 5 or 10 tenants there, he would get in 1 or 2 hired hands and a tractor and the tenant would have to get out.

Dr. TAYLOR. I have seen that in Ellis County, Tex., which I understand is in your district.

The VICE CHAIRMAN. Right in my neighborhood; yes.

Dr. TAYLOR. I have here, Dr. Lubin, a description from the Des Moines Register of March 3, 1940, under the title "Tractor brings trend toward fewer and larger farms in Iowa," which tells exactly what is happening. I don't know whether you wish to hear it.

The VICE CHAIRMAN. Let's hear it.

Mr. TAYLOR (reading):

Is it "good" or is it "bad"? Is it toward an agriculture based on a more stable family-sized farm or is it toward a different kind of farming community?

Apparently the movement is dual. In some instances it is toward a healthier farm community in terms of the past—the owner-operator farming with little or no hired help but with all members of the family pitching in, the individual farm and the community based on farming as a way of life as well as a business. But in other instances the change seems clearly to be toward something different. AND THE DIFFERENCE BETWEEN THESE TWO TENDENCIES IS LARGELY ONE OF DEGREE.

In some cases, multiple farm operation is undoubtedly better for the soil.

But what about the people? Is it better to have a large number of farm families barely above subsistence levels or a smaller number operating larger units and earning incomes in excess of their minimum requirement? Better, certainly, for those who survive, but is it better for those who lose their farms? THEY MUST BE TAKEN CARE OF—IS IT BETTER TO TAKE CARE OF THEM IN THE COUNTRY OR IN THE CITIES AND TOWNS?

These problems will press us more fiercely if multiple farm operation radically changes our Iowa economy in a direction in which the other phase of the trend seems headed. Larger farms means fewer farms; fewer farmers and more mechanization mean fewer farmers and their families. And this means keener competition among tenants for farms, with greater insecurity for those who get farms and many who do not get farms.

It means a larger transient population, moving from county to county, state to state, with hurt to themselves and damage to institutions like the school. It means, probably, a larger agricultural proletariat class * * *.

This problem, like all problems of its kind, will not be solved by blind passionate opposition. Its solution demands that we answer in our own mind the question, "What kind of an agriculture do we want?"

The VICE CHAIRMAN. What kind of a citizenship do you want, too.

Dr. TAYLOR. Certainly.

The VICE CHAIRMAN. That is involved.

Dr. LUBIN. Does this mean that it is harder for a man to rent a farm in that area now than before the tractor came up?

Dr. TAYLOR. Unquestionably; for many, impossible.

The VICE CHAIRMAN. I live in that country, and the year before last I was in a community where the sons of people whom I had known ever since I have been in Texas, friends of mine, young fellows, wanted to have a home and they were good people. They told

me that it is absolutely impossible for them to rent a place. They were young fellows who wanted to farm awhile and then buy a place after awhile, and they just couldn't rent a place anywhere.

Dr. TAYLOR. Traditionally, we have insisted upon maintaining the agricultural ladder as the opportunity by which men could rise. As the capital equipment on farms increases, it becomes increasingly difficult to ascend that ladder from laborer to owner, and for those who make the ascent it becomes increasingly a matter of inheritance. Those who are not favored in their parentage find increasing difficulties.

The people in the Corn Belt are becoming conscious of that, as I am sure they are in your country.

The fullest development of mechanization with which I am familiar in the field of agriculture is in the fruit and vegetable industry. There, mechanization has transformed market gardening into a highly mechanized industry within a generation, with factory methods of production on the land, factory methods of processing materials, and with hordes of laborers working in gangs at piece rates on the land, moving from harvest to harvest, hired and fired in the manner familiar among old-fashioned industrialists.

There should be called to the attention of this committee, it seems to me, the fact that when mechanization has moved as far as it has in the vegetable industry there is apt to take place an integration, the same sort of thing that occurs in, say, the manufacture of automobiles, a control of the industry spreading from a processor clear back to the land, or from the middleman back to the land.

The concentration of economic power with which you are so familiar in industry has its counterpart in the vegetable industry.

Dr. KREPS. Dr. Taylor, do you have any figures showing the extent to which you have concentration of production in agriculture in California—in various agricultural products?

Dr. TAYLOR. As you know, Dr. Kreps, a subcommittee of the Senate Committee on Education and Labor recently came to California in order to make investigations in agriculture. Their staff has furnished me with a table showing crop concentration. Perhaps the committee would like this introduced in the record?

Dr. ANDERSON. Yes. Mr. Chairman, the table should be admitted to the record.

(The table referred to was marked "Exhibit No. 2685-A" and is included in the appendix on p. 17455.)

Dr. TAYLOR. I think you have that before you. I might then read just three or four examples of the crop concentration.

In canning asparagus, for example, based upon 1939 data, 1½ percent of all producers produced 23.4 percent of the entire product in terms of deliveries to canneries. In cotton production, 3.5 percent of all producers produced 33.3 percent of cotton in terms of acreage.

In lemon production, less than 3 percent of all producers in 1940 produced 34.6 percent in terms of acreage.

There are other ways of measuring concentration. Under the A. A. A. program, for example, the sugar-beet concentration of the production shows 2.1 percent of all payees received 20.6 percent of the total of all payments under the program. For agricultural conservation, 2 percent received 43.6 percent of all payments.

There are other measures also. Ten percent of all farms in California received 53 percent of the 1939 gross farm income; 9.4 percent of all farms made 65 percent of all expenditures for wage labor in 1929.

The VICE CHAIRMAN. Doctor, will you kindly repeat those figures just before you gave us these figures? I would like to ask you to repeat the acreage there, if you have it. Will you repeat the figures just before the ones you have just given?

Dr. TAYLOR. The sugar beets?

The VICE CHAIRMAN. No; the income.

Dr. TAYLOR. Ten percent of all farms received 53.2 percent of the 1939 gross income. Is that it?

The VICE CHAIRMAN. Yes. Now, I wanted to know what acreage, what relative acreage, did that 10 percent in number make up?

Dr. TAYLOR. I am not able to answer that question, but I may say this, that with respect to California, acreage is the most misleading measure of concentration.

The VICE CHAIRMAN. Yes; that is so.

Dr. TAYLOR. Much more in my State, I think, than in yours, because we have everything from range land to irrigated acreage.

The VICE CHAIRMAN. That is right.

Dr. TAYLOR. And very often, on 20 acres, we have a tremendous product. So, I think the measures which are employed in these figures are more accurate than if I tried to give you an acreage figure.

The VICE CHAIRMAN. Yes; I know that is so, and I beg your pardon for asking the question.

AGRICULTURAL CONCENTRATION BY STATES

Dr. ANDERSON. One question before we leave this important exhibit. This, I take it, is a measure of the concentration in California agriculture. Dr. Taylor, are there any comparable figures available anywhere concerning agriculture concentration State by State?

Dr. TAYLOR. There are, Dr. Anderson; I have had prepared the next chart, which—

Dr. ANDERSON (interposing). I think I anticipated you.

Dr. TAYLOR. Shows the percentage distribution of number of farms and value of all products sold, traded, or used in the United States in 1939.

Dr. ANDERSON. That will be admitted to the record.

(The chart referred to was marked "Exhibit No. 2686" and appears on p. 17057.)

Dr. TAYLOR. You will observe there that 1.4 percent of all of the farms of the United States produced 15 percent of all products by value, or combining the lower two categories, that 3.9 percent of all farms produced 25.6 percent of all products by value. The chart which follows presents figures for the United States on another basis.

(The chart referred to was marked "Exhibit No. 2687" and appears on p. 17058.)

Dr. TAYLOR. This chart classifies farms of the United States in terms of the numbers of laborers employed per farm. In July of 1935, this was estimated by the Social Security Board from the census of 1935 and the seasonal indices of the Bureau of Agricultural Economics.

May I call your attention to the fact that some 78 percent of all farms in the United States, of the 6,800,000 farms, employed no laborers, no hired laborers at all.

Dr. KREPS. Do you mean to imply by that that taxes on labor, such as social security taxes and others, would leave such farms completely exempt?

EXHIBIT No. 2686

[Submitted by Dr. Paul Taylor]

UNITED STATES

PERCENTAGE DISTRIBUTION OF NUMBER OF FARMS AND VALUE OF ALL PRODUCTS SOLD, TRADED, OR USED. 1929

SOURCE: COMPILED FROM 1930 CENSUS

Dr. TAYLOR. Virtually that, Mr. Kreps. You realize that this figure is employment at a particular month in the year, so it is not identical with your question, but it comes fairly close to answering your question.

Dr. KREPS. Would you say that July was a period in which, on the whole, the amount of farm labor would tend to be as large as in any other month during the year?

Dr. TAYLOR. Something below the peak. It is a month of large employment, but below the peak.

Dr. KREPS. At any rate, better than average, possibly?

Dr. TAYLOR. It is average or a little better.

EXHIBIT No. 2687

[Submitted by Dr. Paul Taylor]

UNITED STATES

FARMS AND WAGE WORKERS, BY NUMBER OF WAGE WORKERS PER FARM

CUMULATIVE PERCENTAGE DISTRIBUTION ESTIMATE

JULY 1935

SOURCE - WENZEL, SOCIAL SECURITY BOARD

Dr. KREPS. That would mean then that, on the whole, we tend to subsidize, as I get it, large-scale agriculture in the United States and mechanization in large-scale agriculture?

Dr. TAYLOR. Well, it seems to me that there is another way of looking at the exemptions from social legislation which generally Congress has granted to agriculture. I think in general it has been felt that because of the peculiar importance of agriculture to our national life, and for some other reasons, it was appropriate that social legislation should exempt agriculture.

I think upon examination of "Exhibit No. 2687" it becomes plain that that is not exactly what we have been doing. On the contrary, you notice that most of the farmers employ very little or no labor. It has been proposed by the Social Security Board, for example, that old-age insurance should be extended to cover hired farm laborers with exemptions for the family farmer. So that an agricultural labor exemption which is complete in its coverage of agriculture, it seems to me, may well be looked at as a public subsidy, not to agriculture in general but to a particular manner of carrying on agriculture. In other words, it is industrialized agriculture which in a sense is in competition with the working farmer, that we are subsidizing by our so-called exemptions to agriculture, and insofar as mechanization plays its role in building up an industrialized form of agriculture we are thereby subsidizing further displacement from the land and reduction of working farmers in status.

Dr. KREPS. I believe you will recall that there was a reemployment commission recently, will you not?

Dr. TAYLOR. Yes.

Dr. KREPS. Do these farm laborers receive support from other groups, and particularly from governmental groups, in addition to the support which they receive during the time they are employed on the farm? Is there a seasonal problem there?

Dr. TAYLOR. In terms of relief?

Dr. KREPS. Yes.

Dr. TAYLOR. There is a very serious relief problem, and the curves of employment on the land and of relief show a very considerable dovetailing, which means, of course, that the taxpayers of California are supporting the unused labor supply of the agricultural enterprises during their slack seasons.

May I ask, with further reference to the suggestion that I have just made, that we look again at the effects of the agricultural exemptions which we have granted in the past. The President's Farm Tenancy Committee of 1937 recommended to Congress that it give very careful consideration to the extension of social-labor legislation to agricultural enterprises above the size operated by the working farmer.

Dr. LUBIN. Dr. Taylor, if the social security, that is, the unemployment compensation and old-age insurance, were made applicable to agriculture, as far as this industry itself is concerned, only about 20—what is it, 21 percent of the farmers!—would have to pay any taxes for social security; is that right?

Dr. TAYLOR. It depends on where the exemption is drawn.

Dr. LUBIN. I don't mean—

Dr. TAYLOR (interposing). If it covered all of the labor, the figure based upon the 1935 census is something like 22 percent.

Dr. LUBIN. In other words, 22 percent of the farmers would have to bear the burden?

Dr. TAYLOR. That is right.

Dr. LUBIN. That is, pay taxes. Now, if you put it at, let's say you exempted every farmer who had one employee?

Dr. TAYLOR. If you exempted every farmer who has 1 employee, only 6 percent of the entire 6,000,000 would be covered. You understand, I am giving you simplified figures that would need elaborating in a more careful discussion.

Dr. ANDERSON. Suppose you made it on a parity with present conditions of the Unemployment Compensation Act; how many farmers would be affected, how many employers? What would the proportion be?

Dr. TAYLOR. Well, the Unemployment Compensation acts vary from State to State, I believe. The Federal has an exemption of four.

Dr. ANDERSON. That is right.

Dr. TAYLOR. A good many States, I think, have no exemption.

Dr. ANDERSON. Suppose we took an exemption of four?

Dr. TAYLOR. Well, if you took four, it appears that 1.6 percent of our agricultural employers employ something over one-third of all the hired labor. May I point out a further aspect of this problem of coverage of agricultural employers and their employees by social and labor legislation? May I refer now, Dr. Anderson, to my next chart? It is the average cash expenditure for labor performed, reporting by tenure of operator.

Dr. ANDERSON. That will be admitted.

(The chart referred to was marked "Exhibit No. 2638" and appears on p. 17061.)

CASH PAYMENTS TO LABOR

Dr. TAYLOR. This chart is derived from the 1930 census. It shows the average expenditures in cash for farm labor per farmer reporting. In other words, all of the farms which spent no cash for labor are excluded, and we are dealing here only with that minority of farms which spent money to hire labor.

Please note, at the top, for the United States as a whole, the average cash expenditure for farm labor was \$356, by owners. The open bars refer to owners, the next bars refer to tenants, and the solid black bars refer to farms operated by managers. Please note that the average expenditures for owners are \$365 a year; for tenants, \$261 per year; and for managers, \$2,985.

Dr. TAYLOR. The chart permits you to carry out comparisons of that kind through every division of the country. The point of the chart is this: That the manager-operated agricultural enterprise typically is the industrialized enterprise, and if these so-called agricultural exemptions were removed, retaining always an exemption for the man who is a bona fide working farmer, the enterprises which would be most surely covered, are those where the manager-hired labor type of industrialized agriculture has developed.

Dr. LUBIN. In summarizing your previous statement then, is it fair to say that insofar as your agricultural industry does not give steady employment and consequently, places upon the rest of the economy the burden of taking care of the people who are not unemployed during

periods of slack, that 78 percent of the farmers insofar as they are taxpayers, and consequently through their taxes, are helping to support the unemployed, are helping to bear the burden to provide a sufficient—

AVERAGE CASH EXPENDITURE FOR LABOR,
PER FARM REPORTING, BY TENURE OF OPERATOR

SOURCE: 1950 CENSUS

FARMS NOT REPORTING EXPENDITURE FOR LABOR ARE EXCLUDED

Dr. TAYLOR (interposing). In connection with which they have now a problem.

Dr. LUBIN. To the other 21 percent, when they need a sufficient supply.

Dr. TAYLOR. The answer, Dr. Lubin, is yes. I would like to make just one additional remark at this point, so if anyone examines the

record, he will realize that these conclusions are based upon that single estimate. There should be compared with these estimates the expenditures for labor derived from the 1930 census, so that you cannot say, 21 and 78 percent. You must give other estimates which show a range.

In principle, your statement is correct, but I wouldn't want someone to read from the record and quote me as apparently ignorant of the fact that other estimates might be made which would vary somewhat from the answer I have given.

Dr. ANDERSON. Go ahead.

Dr. KREPS. Pursuing that question of integration, Dr. Taylor, just a bit further, as I understand this statement of yours, this isn't only a matter of concentration of production in agriculture as such, but an interrelationship between agriculture and variety of enterprises of industries, that is, concentration in agriculture as a part and parcel of concentration in variety of industries. Is that correct?

Dr. TAYLOR. I think that is essentially correct, Mr. Kreps. You are undoubtedly familiar with the reports of the subcommittee of the Senate Committee on Education and Labor, which have developed that, I think, very fully. They have pointed out, for example, the development of large-scale processing corporations which move back into control of the land through ownership, through financing, leasing arrangements, and so forth.¹

Again, my emphasis is that although in California we perhaps have the most extreme development of this industrialized and integrated agriculture, it is very conspicuous in quite a number of other parts of the country. For example, one of our largest corporations, the California Packing Corporation, to quote from some testimony which recently was introduced into the Senate committee record, "the California Packing Corporation owns and operates some 20,000 acres of farm land in California, valued at \$9,000,000. In Illinois, Hawaii, and the Philippine Islands, the corporation leases and operates 47,000 acres additional. The American Fruit Growers, Inc.," continuing the quotation, "is another Nation-wide shipping and brokerage firm which controls a considerable amount of farm property. It owns some 15,000 acres of farm land in 10 States, of which 2,500 were planted with citrus fruits, grapes, and vegetables in California. In 1936, this company handled 34,225 cars of fruit, of which about 9,000 cars originated in California and Arizona, where the company maintains 31 packing houses."

Mr. PIKE. They get the same exemptions from social security, wages and hours, as any farmer would get, do they?

Dr. TAYLOR. It would be difficult to answer your question yes or no, because each of the laws has its own definition, its own—

Mr. PIKE (interposing). The statute would vary?

Dr. TAYLOR. The statutes vary. I have been discussing in these charts the employment of workers for cash on the land. Now, I point out the fact that the processing industry has moved back on the land. The exemption of those who work in the processing plants, and those who work on the land for farmers are somewhat different in nature.

Mr. PIKE. Yes; but these people, when they are farming, get all the compensations that family farmers get? I mean in their farm operations.

Dr. TAYLOR. Not entirely, but to a large extent, that is true.

¹ See Hearings before the subcommittee of the United States Senate Committee on Education and Labor, Part 47, pp. 17353 ff.

Dr. LUBIN. Well, as far as they employ workers in agriculture on the land they are exempt from social security and the wage-and-hour law, those people.

Dr. TAYLOR. I believe that under the latest amendments, that is so.

Dr. LUBIN. But as I understand the law itself, in other words, the corporation happens to be running a farm and doesn't pay any social security taxes for the workers working on that farm directly, that is, on the land hoeing, plowing, and so forth.

Dr. TAYLOR. They did until the amendments of a year ago.

Dr. ANDERSON. Are we to understand, Mr. Taylor, that these corporate groups engaged in processing, moving back now onto the land, who come from California and ramify out into other States and other counties, are to be found not only in California, but elsewhere over the country, that is, developing to the extent that this begins to characterize an aspect of the agricultural change?

Dr. TAYLOR. It appears to be of growing importance. Certainly it characterizes portions of the country like Florida and south Texas and other important fruits and vegetable producing areas. I think it is a very significant development.

Dr. ANDERSON. Has it moved beyond the fruit and vegetable producing groups into any of the other agricultural groups that you know of?

Dr. TAYLOR. I do not.

Dr. ANDERSON. Milling houses, for example are not engaged, as you know them?

Dr. TAYLOR. I am not able to answer.

CITIZENS' ASSOCIATIONS AND FARM LABOR

Mr. KREPS. Again, referring back to this report by the Committee on Education and Labor, on violations of free speech and rights of labor, and particularly part 46, I notice throughout that subpoenas are issued to about the same groups. Is this an integrated group? Was this subpoena issued on the whole to the same group but with different interests? I'd like to read some of this group to you because the variety of interests involved is truly amazing. They start with the Associated Farmers of California. I presume that is the farm organization.

Dr. TAYLOR. That is the organization of the agricultural employers.

Mr. KREPS. Then I notice immediately Industrial—

Dr. TAYLOR (interposing). Processors.

Mr. KREPS. Yes. Then I notice Industrial Association of San Francisco. Is that affiliated with the farm group?

Dr. TAYLOR. It had relations with the Associated Farmers. I believe the committee reported or found that it had financed in part the Associated Farmers. The Industrial Association no longer is in existence.

Dr. KREPS. Well, then, I notice that they have the Growers-Shippers Vegetable Association, as you indicated a moment ago, a citizens' association of various areas. Then the California Processors and Growers, and then the chambers of commerce, I take it, in California, find kindred interests in the agricultural groups.

Dr. TAYLOR. I believe, Dr. Kreps, that the committee was concerned with these various organizations because it was endeavoring to ascertain the facts concerning interrelationships which developed concen-

tration of economic power. I am not in a position to speak in the fullest detail. I am sure they appear amply in the reports. I know that it is the purpose of the committee, in general, to discover those relationships, and I assume that that is why those subpoenas were issued. Its reports will show the facts in full concerning your question.

Dr. KREPS. That means, then, that on the whole the assumption is correct that these organizations are all interrelated and subject to a common control, for example, the Association of San Francisco Distributors, the San Francisco Retailers Council, the Water Front Employers Associations, and Southern Californians, Inc.?

Dr. TAYLOR. I am speaking now from newspaper reports written very largely at the time that the Senate committee held its sessions. I believe it is largely an employers' organization which has had very close relations with the agricultural employers.

Dr. KREPS. Organized to attract tourists?

Dr. TAYLOR. No, not at all; concerned to a considerable extent with labor relations on the farms in California.

Dr. KREPS. I notice other organizations, the Union of California Citizens, California Crusaders, Neutral Thousands, Women of the Pacific, Merchants and Manufacturers Association, East Bay Defense Association. Are those interrelated?

Dr. TAYLOR. They are a wide variety of organizations into which the committee made inquiries. No simple answer would cover, and in fact I can't give you a categorical answer with respect to them, but I am sure that the Senate committee report which is now in process of publication would carry a full answer to your questions. I was furnished today with a typewritten listing of expert testimony presented at hearings of the Subcommittee of the Senate Committee on Education and Labor with reference to the concentration of economic power in agriculture and allied industries in California.¹ It may be that you would wish to carry this in your record. I am sure it would answer your questions more completely and satisfactorily than I can.

Dr. ANDERSON. The exhibit is accepted for the record.

(The document referred to was marked "Exhibit No. 2689-A" and is included in the appendix on p. 17456.)

Dr. KREPS. I get the impression that this is a regional economic empire. Do you know whether it obtains on the Pacific Coast?

Dr. TAYLOR. Perhaps that is a good way of characterizing it. Certainly the interrelationships between the various elements of industry and agriculture are close and the controls are more or less centralized or at least coordinated, I think, to a rather surprising degree.

Dr. KREPS. So that the mechanization in agriculture is tied up with mechanization in industry and gives us a concentrated economic control both of agriculture and industry.

Dr. TAYLOR. I think the evidence shows a good deal of what you have just stated.

The course of mechanization and economic development has run so far in sections of the fruit and vegetable industry, that the patterns produced by its advanced stages of development, merit examination. As early as 1929 Wells A. Sherman, late chief marketing specialist of the Bureau of Agricultural Economics said:

¹ See hearings before the subcommittee of the United States Senate Committee on Education and Labor, pt. 46.

"Within a generation market gardening has largely changed from a hand and horse to a mechanized industry. The changes in the production and handling of most of our annual vegetable crops have been generally comparable to the changes in industries once conducted in homes or private shops but which are now centralized in immense factories. These changes begin with seed production and run through to the final delivery of the goods to the consumer. They comprehend all of the changes from their small beginnings to the present era of mass production.

"* * * squat labor is as essential to our mass production of some vegetables as is the tractor or power sprayer * * * In the harvesting of most truck crops and all fruit crops a large amount of hand labor is still necessary. To meet this need we have thousands of itinerant harvesting and packing crews in the fruit districts picking the fruit from the trees and performing every operation in the packing house; in the vegetable districts, selecting and picking cantaloupes or tomatoes, or * * * cabbage. Mass production has thus brought about what may be called the mechanization of the human element in the industry. The harvesting gangs are called in when wanted just as the tractor and the gang plow are brought out of the sheds when needed. These waves of itinerant labor ebb and flow with the seasons. Almost every district of important specialized commercial production counts upon them as it counts upon the succession of the seasons * * *.

This policy of "hire and fire," without responsibility for carrying the overhead cost of supporting their laborers between seasons is itself a contributory factor to that acute specialization which makes employment so highly seasonal and laborers so mobile. Under this system, which utilizes foremen, gang labor, piece rates, recruiting by labor contractors, the personal paternalism traditional between farmer and hired man is virtually absent, unemployment is intermittent and severe, milling about from crop to crop is necessary in order to obtain work, the average annual earnings are low despite wage rates which appear high, and opportunity to ascend the agricultural ladder from laborer to tenant is practically closed.

In some areas, particularly in the West, the vegetable industry has become highly integrated, not infrequently with a single corporation carrying on every phase from planting the seed to marketing the product in cities 3,000 miles away. Some corporations maintain extensive field and processing activities scattered all the way from Washington and Arizona to Florida. Ranch headquarters maintain direct wire services to sensitive eastern markets, and have the appurtenances of modern business offices.

FUTURE OF FAMILY-SIZED FARM

Dr. TAYLOR, May I, in conclusion, on the California situation, quote to you briefly from the official organ of the fruit and vegetable industry in our State, the Western Grower and Shipper of Los Angeles, which describes itself as "a monthly publication serving the West's great fresh-vegetable and melon-growing shipping industry." It says in October 1939 that the family-size farm cannot survive in California agricultural industry, particularly of its type:

It is true, of course, that a large sector of California agriculture is industrialized. * * * The incidents of husbandry, the family-sized farm with all of its pastoral glamor, is a lovely idyll—elsewhere than most sections of California. California is not unfriendly to husbandry and farming as a mode of life, but costly experience has shown that a large percentage of its acres, no matter how attractive to the inexperienced eye, are not suited to such purposes. The history of attempted development of many sections now successful under industrialized agriculture to small farming is a history of blasted hopes and broken hearts.

Mr. PIKE. Do you subscribe to that view?

Dr. TAYLOR. I think, on the whole, that is pretty close to the truth. You understand I am not generalizing for the United States as a whole.

Mr. PIKE. But where irrigation costs are high, and all that?

Dr. TAYLOR. Yes. The course of economic development very clearly is adverse to the family farm. We had them there. They were swept out by the process which I have been describing.

Dr. ANDERSON. Do you generalize from that? Would you care to even hint at such possible tendencies with respect to the rest of the country and other crops?

Dr. TAYLOR. I think that the testimony which I have prepared, not all of which I have read, but which I take it you are more or less familiar with, shows very clearly the appearance in widely separated areas of agricultural production on a pattern of industrialized agriculture—the Wheat Belt, the Corn Belt, the Cotton Belt, fruits and vegetables.

The VICE CHAIRMAN. Doctor, do you find any parallel between this tendency with regard to agriculture and the tendency of a good many years ago, which has greatly developed now, where the little manufacturer went out of business?

Dr. TAYLOR. I think that there are a great many parallels between the entry of machines on a large scale into agriculture and the entry of machines into industry. Certainly I think we are in the earlier stages of an important counterpart to what we call the industrial revolution.

The VICE CHAIRMAN. Isn't that perhaps one of the biggest things in this whole picture to be looked at?

Dr. TAYLOR. It seems to me that it is.

The VICE CHAIRMAN. You have something to go out and sit on the fence a good while and think about.

Dr. TAYLOR. May I, Congressman, read a couple of pages which will perhaps open up some other aspects of this problem? I want to speak for a moment on changes in status of farmers and the hired man.

Ninety years ago during the debates on the homestead bill, a Congressman from Indiana voiced the traditional American ideal of working farmers on the land in these words:

Instead of baronial possessions, let us facilitate the increase of independent homesteads. Let us keep the plow in the hands of the owner. Every new home that is established, the independent possessor of which cultivates his own freehold, is establishing a new republic within the old, and adding a new and strong pillar to the edifice of the state.

American land policy and pioneer conditions developed a common type of farm-operator known as "the farmer," distinguished alike from the European peasant and the landlord. "The farmer," says Dr. Joseph Schafer of the State Historical Society of Wisconsin, in a description of the type, "is one who operates a 'family-sized farm' for a 'living,' rather than for 'an actual or potential modern fortune'; a farm on which the owner and his son or sons can perform the actual work of tillage, the female members of the household smoothing the way by providing home comforts, assisting about chores, or in field or meadow as pressure of work may indicate. Hired men are rather the exception than the rule in this typical agriculture. So far as they are employed, it is usually with the instinctive purpose of raising the labor force to

the normal family plane rather than in hope of abnormally expanding the business beyond the family-farm size."

The progress of technology on the land not only displaces many of this type of farmer and his hired men; it also changes their status. The type of land operator which may result when change runs its full course can be illustrated from the citrus industry of southern California. The "farmer" is being displaced there not physically, but in a far subtler fashion which leaves him a resident on the land, but strips him of the traditional functions of a farmer who tills the soil. The packing of his fruit is usually performed in large packing plants cooperatively or privately owned, valued on the average at \$100,000, highly organized, and not located on the farm. But more than that, even the work in the grove of pruning, fumigating, spraying, picking, and so forth, commonly is performed by gangs of laborers under contract, or employed and directed by the manager of a citrus association. In an economic affidavit prepared for California citrus employers this has been stated by J. Eliot Coit very succinctly:

The term "farm" in the old or commonly accepted sense in the East, South, and Middle West is long since obsolete in respect to the highly specialized agricultural occupation of growing such products as citrus fruits, walnuts, avocados, and a large number of other specialty crops grown on the Pacific coast.

In some instances this removal of the farmer from work has become so complete that Mr. Coit declares:

In fact, there are some farmers who do no manual work on their farms.

To most Americans accustomed to thinking of farming as a family enterprise carried on by a "farmer" working beside his sons and an occasional hired man, these citrus growers clearly are no longer "farmers." Their functions, as such, have been progressively assumed by associations, corporations, and labor contractors.

Another subtle change away from the American farmer type results from replacement of "farmers" by managers, especially on large-scale and multiple farms. Such absentee operation of the land is perhaps more common than supposed. According to the census of 1930, one-eighth of all cash wages paid to farm laborers in the United States were paid by farm managers, and in Arizona and California one-quarter.

These changes which affect the status of the farmer have their counterpart in changes which affect the wage worker. It is a far cry from the migratory gang labor of industrialized cotton farms and the vegetable industry to the "hired man" described 20 years ago by Henry C. Taylor, now head of the Farm Foundation, in these words:

On the general farm in the northern part of the country the typical wage worker on the farm is a young man who is temporarily a member of the farmer's family as well as part of the farm crew. He eats at the family table, reads the paper in the family living room after supper, puts his soiled clothes into the family washing, and in general shares the life of the farm home. If he is a good hand he will soon become interested in the work of the farm and attached to the farm by many ties other than the wages he draws. This young man is a part of the farm family, and whether he is contented with the life and interested in the work depends largely upon the success of the farmer and his wife in developing sympathetic and happy relations. There are no class distinctions. The young man expects to become an independent farmer and feels that he is gaining skill, money, and credit which will enable him to establish a home of his own in a few years.

That is a picture of a scene which is passing in many parts of the country.

The VICE CHAIRMAN. Doctor, that was largely true, too, with the small cabinet maker, the small implement maker, just a few decades ago.

Dr. TAYLOR. Yes; the apprentice became the journeyman, married the daughter of the master, and became a master himself.

Dr. ANDERSON. I take it that is what you implied by "the ties that bind."

Dr. TAYLOR. If I may proceed, I have about 3 pages more which bring this together.

Perhaps I am wearing you out.

The VICE CHAIRMAN. No, sir, you are not. You are one doctor that seems to know what he is talking about.

Dr. TAYLOR. The course of mechanization in agriculture reveals a strong economic pressure to expand the scale of farm operations. Enlargement of the farm results in manifest benefits to those who are successful in thus obtaining fuller utilization of their machines, and some benefits may accrue also to laborers who are retained. But the effects of technology fall unequally upon our agricultural classes.

DISPLACEMENT OF FARM OWNERS AND LABORERS

Dr. TAYLOR. Many farm families—both farmers and laborers—are being displaced completely or driven into uneconomic subsistence agriculture. The result of combined forces—a narrowed outlet for farm youth in industrial employment, a high rural birth rate, and the introduction of machines—is a piling up of rural population on poorer lands. The Dallas Farm News, citing a study of the United States Department of Agriculture, stated on April 5:

Mechanization has driven many of the farmers from the better land and forced them to live on poorer land, subdividing the remaining small farms in poorer areas.

When mechanization achieves success in planting and cultivating, but not in harvesting a crop, agricultural employers must then depend for the harvest upon hordes of underemployed, mobile laborers. These conditions are conspicuous already in vegetable and fruit production and are spreading in cotton. This stratification upon the land is accompanied by bitter strife. It has appeared in the Arkansas delta and the Missouri boot-heel, in the onion fields of Hardin County, Ohio, where industrialized agriculture is conspicuous, in the potato fields of southern New Jersey, the pea fields of Idaho, the cotton fields of Arizona, the orchards of Yakima Valley, Wash. Its intensity in California and adjoining States moved the United States Senate last year to appoint a committee to investigate and report on violations of civil liberties in agriculture on the Pacific coast.

The socio-economic displacement pattern varies when mechanization of all processes from planting to harvest is completed. The seasonal laborers in wheat are virtually eliminated from all employment where the combine harvester is adopted. Farmers are completely displaced by enlarging farms, and merchants suffer. The success of sugar beet or onion harvesting machinery would strand the communities of beet and onion tenders now resident and necessary in Colorado and Ohio.

In the Corn Belt the effects seem to follow different directions. Expansion of the farms of middle-sized farmers eliminates other middle-sized farmers and smaller farmers. Carried far, this trend results

in industrialized farms, multiple farms, change in status from tenant to hired labor, displacement of both laborers and farmers, and commercialization of the relations between agricultural employers and those wage workers whom they retain.

On March 3, 1940, the Des Moines Register, in the heart of the Corn Belt, stated:

All in all, our Iowa agriculture may be on the road toward a sharp division into three kinds of farming: (1) large, highly industrialized, commercialized and mechanized crop farms; (2) specialized farms such as for dairy and hog operations, which are largely independent of the size of the farm and have been profitable in spite of ruinous grain prices; and (3) subsistence farms, growing as much as possible for home consumption.

A few of the implications are suggested: An emotional and political alignment of the farm-operator with the industrialist of the city and of the farm laborer with the urban laborer; a decreasing birth rate among the farm population, which is the principal source of repopulation of our cities today; a lower standard of education and culture for those who migrate to other parts of the Nation.

The story, in brief, could be the sacrifice of agriculture as a way of life for the many upon the altar of agriculture as a way of making a living for the few.

The trend hasn't gone far in this direction yet. And there are forces working against it. Tenants compete for farms. Attention is being focused upon their problems and they are being encouraged and helped to secure better tenure or to purchase their farms by Farm Security Administration and others.

The great mass of Iowa farmers strongly opposes the change toward fewer and larger farms. Greater value has recently been put upon the nonmaterial elements in rural life. There is a law of "diminishing returns" in operating large farms in Iowa, as elsewhere—the bigger the farm the higher the profits in good times under good management, but the bigger the loss in poor times or under inefficient management.

But economic factors are working toward larger and fewer units * * *

Sometimes it is well to look backward also as we strive to see ahead. About three generations ago Daniel Webster said:

Our New England ancestors brought thither no great capitals from Europe; and if they had, there was nothing productive in which they could have been invested. They left behind them the whole feudal policy of the other continent. * * * They came to a new country. There were as yet no lands yielding rent, and no tenants rendering service. The whole soil was unreclaimed from barbarism. They were themselves either from their original condition, or from the necessity of their common interest, nearly on a general level in respect to property. Their situation demanded a parceling out and division of the land, and it may fairly be said that this necessary act *fixed the future frame and form of their government.* [Webster's italics.] The character of their political institutions was determined by the fundamental laws respecting property * * * The consequence of all these causes has been a great subdivision of the soil and a great equality of condition; the true basis, most certainly, of popular government * * *

The freest government, if it could exist, would not be long acceptable, if the tendency of the laws were to create a rapid accumulation of property in a few hands and to render the great mass of population dependent and penniless. In such a case, the popular power must break in upon the rights of property, or else the influence of property must limit and control the exercise of popular power. Universal suffrage, for example, could not long exist in a community where there was great inequality of property. The holders of estates would be obliged in such case either in some way to restrain the right of suffrage, or else such right of suffrage would ere long divide the property.

Already we hear half articulate appeals from distressed and fearful farmers against "land monopoly," "land hogs," and "tractoring out." We see vague efforts to curb expansion of farms, or to distribute land more widely. Their aim is somehow to hold a broad popular base on the land. Also we hear talk of placing limits on the right of suffrage of those who are victims of mechanization in

agriculture. Native white American farmers displaced by power farming in Texas and Arkansas are virtually disfranchised by older poll-tax statutes.

The VICE CHAIRMAN. What was that statement?

Dr. TAYLOR. Native white American farmers displaced by power farming in Texas and Arkansas are virtually disfranchised by older poll-tax statutes.

The VICE CHAIRMAN. A poll tax disfranchises? Do you make that statement on your own responsibility?

Dr. TAYLOR. I have been informed by many who are so disfranchised—you understand the reason they are disfranchised is when they are stripped of their property, they don't feel able to pay the amount of money required in your State, and they are, many of them, many of your white tenant farmers whom I have seen, reduced to such estate that they don't feel able to pay the tax.

In California attempts are made to restrict the vote of migrant workers who serve our agriculture.

The issues which we face in the effort to distribute the benefits of machinery more broadly among our agricultural people are not alone economic. That they are also political in a fundamental sense is coming to be recognized. A week ago the chairman of the 1938 farm tenancy committee of Iowa said of this problem:

I am fearful that unless something is done about it within the next decade it will bring about and develop such unrest among our people that it will threaten our democracy.

MECHANIZATION AS A FORCE FOR EXPANDING ACREAGE

Dr. ANDERSON. Dr. Taylor, Mr. McCormick said this morning: "The recent technological advances in farm machinery from which the family-sized farm will greatly benefit may well become a bulwark to preserve this important part of our social structure." I take it the discussion this morning hinged largely on the fact that we are now changing from a kind of mechanization which benefited particularly the large scale corporation and manager farm that you have been discussing, to a kind which benefits particularly the family-sized farm. The implication is that this new type of mechanization may make it possible to equip a family-sized farm with the necessary machinery to enable them to compete successfully with larger units, and that mechanization now becomes a great benefit rather than a hazard to independent farmers.

What is your position with respect to that?

Dr. TAYLOR. In other words, the argument runs that the small farmer now has a security and independence on the land which he has not had in years recently past because of the rapid development of smaller machines which he is able easily to purchase. I cannot share the optimism of that position, and I agree with the statement which was made by an earlier witness before this committee, Mr. Sherman Johnson, of the Department of Agriculture, when he said that when the small farmer buys a tractor and machinery to go with it, he has capacity to operate more land. In other words, when the machinery is there, there is economic pressure to use it to the full. You can't simply put your tractor and all the auxiliary machinery in the shed with no expense to yourself. You can cut off the fuel expenses, to be

sure, but you can't cut off the overhead costs, the depreciation of that machinery. It is good farm management practice, I believe, to use your machinery to the full, to use your own labor to the full, and that pressure which exists, it seems to me, will continue to exist when the smaller farmer is able to buy machinery which now is not available to him.

It may well be that the small farmer would like to come in from the field earlier and read his paper in the evening in the parlor of the house, and leave his tractor in the shed, but it seems to me that the pressure of costs and the chance to earn wages for himself in operating the machine to maximum capacity will prevent many of them from doing what undoubtedly they would like to do. I don't say that none of them will do it, but I say there exists this continuous and strong economic pressure which prevents me from accepting that conclusion.

It seems to me, then, that while the smaller machinery may enable some small working farmers to resist displacement and hold their places on the land, it is more likely actually to spread the area of displacement into places where it was not taking place before.

May I illustrate that with perhaps two examples. The first is the combine harvester. I believe that the large combine harvesters operated first in the western wheat country. The Corn Belt was closed to them by their great size and cost. When smaller machines were developed, smaller combines with shorter cutting bars; it was possible to use combines in the Corn Belt, so the area of displacement spread from the great wheat country of the plains and California to the Corn Belt, where previously it had been absent.

And it is this same pressure to which I referred earlier, to use the machine to capacity, that makes the owner of the smaller machine wish to enlarge his farm when he gets his combine and other machinery.

Another illustration, it seems to me, can be derived from the history of the introduction of tractors. In my part of the country, on the west coast, we are pretty highly mechanized. We use to a considerable extent the caterpillar tractor or tracklaying type of tractor, many of them huge machines costing a good many thousands of dollars. These machines, which are so familiar in California and Arizona, occasioned no displacement at all in the western dry country of Texas, or in the black lands of Texas. It wasn't until much smaller machines were developed in the form of the all-purpose tractor that displacement by machinery entered into the high plains of Texas and the black lands of the Delta; so it was the smaller machine, costing perhaps a quarter or less of the cost of the large tractor, which spread displacement into an entirely new area.

In the western part of Texas and Oklahoma the all-purpose tractors for some years have been operated with 4-row cultivating equipment. As smaller tractors are developed they pull 2-row and 1-row outfits. It seems to me that the natural effect of those smaller machines will be to spread the displacement into areas of the cotton belt where, for reasons of topography or otherwise, the larger machines with 4-row cultivators couldn't operate.

May I repeat, I am not attacking the machines any more than the Congressman is attacking them. I am trying to answer the question, and to point out that I do not believe that continued mechanization in terms of the small machines offers a stable bulwark against displacement at certain points. It may assist the small working farmer

to maintain a balance for a time. For how long I don't know. But its additional effect will be to spread the area of displacement where it did not occur before. That, of course, refers to the farm operator. It is plain that the smaller machines are bound to displace hired workers, and indeed they are advertised to do exactly that.¹

Mr. PIKE. I would like to ask you, Doctor—it worries me a good deal—about these people who are required at harvest time only, in some of these highly mechanized farming operations that you have mentioned. Here the farms are going to need operators for a week to 2 weeks or 6 weeks, and here, scattered all over the State or over several States are relief camps operated by the Government, some of them perhaps of the sort you showed us in the photograph.

Dr. TAYLOR. Those camps which I showed in the photographs are not Government camps.

Mr. PIKE. I realize that. They are overflow. But here are these pools of unemployed workers and here are these jobs that are coming up. I think it would be a grand chance for the industrial people to get working with the people who are managing relief so that the unemployed laborer is in a warehouse just as truly as the unemployed machine, with the exception that the farmer doesn't have to pay his depreciation, even, or any of his support. He can pull him out of the relief camp or off the relief rolls almost the moment he needs him, but the worst of it is, he shoots him back there the moment he is through with him, so that the Government supports and—

Dr. TAYLOR (interposing). Someone else carries the overhead.

Mr. PIKE. And if it weren't done in a highly legitimate manner, requiring almost inhumanly perfect management, you would think there would be a chance for dovetailing and you would have the boys on the job for a few days and then back in the cooler. It is one of the greatest possibilities for the inhuman handling of labor that I ever saw. Have you seen some of that, or am I describing something that doesn't exist?

Dr. TAYLOR. I am not familiar with the industry-relief dovetailing.

Mr. PIKE. I mean the agricultural labor and the relief.

Dr. TAYLOR. Oh, yes; that is the constant procedure.

In other words, the relief administration in California stores a large percentage of the workers engaged in agriculture.

Mr. PIKE. You are subsidizing the big farm people again.

The VICE CHAIRMAN. I would like to know if anybody has an opinion as to whether or not these migratory peoples become accustomed to that way of living, and wouldn't like to change it.

Dr. TAYLOR. Congressman, I think I can answer for the people who have come from Texas and Oklahoma and adjacent States. They don't like the migratory labor life which we provide for them in California.

¹On June 20, 1940, Dr. Taylor submitted the following relevant quotation from "Economic Information for Wisconsin Farmers, prepared by members of the staff of the College of Agriculture" (December 1939):

"It has been estimated that the power and machinery on Wisconsin farms at the present time would be sufficient to handle satisfactorily two or three times the acreage now covered. . . . A farm of 40 to 60 crop acres usually has a rather complete set of farm machinery and in many cases these machines could successfully handle a much larger acreage. For example, a man with 15 acres of hay would probably have a 5-foot mower, a side-delivery rake, and a hay loader; a man with 45 acres would probably have the same machines; thus the investment per acre is only one-third as much on the larger area. . . . Many farmers are enlarging their farms by buying or renting neighboring farms in order to utilize their equipment to a greater extent. Even though there is a notable tendency to develop equipment suitable to small farms, further mechanization may tend to result in increased size of farms and reduced farm labor requirements."

The VICE CHAIRMAN. They would like to settle down somewhere?

Dr. TAYLOR. They would like it very much.

Dr. KREPS. Dr. Taylor, I had an uncomfortable feeling during part of this afternoon of rereading Gibbon's Decline and Fall of the Roman Empire, where he described the displacement of the independent farmers by formation of huge latifundia operated by slaves. I also agree with Mr. O'Connell that I hate to just sit around and hope for something to happen. I wonder whether you could not tell us what might be done. Do you have any recommendations that you could make to us that might serve a useful purpose in the problem?

RECOMMENDATIONS TO ELIMINATE DISPLACEMENT

Dr. TAYLOR. I have some rather specific suggestions which might be helpful. I have tried to suggest things that are practicable, that can be done and done fairly soon. I have suggested already that we stop subsidizing displacement by giving exemptions which are not exemptions to the working farmer. That I have already discussed and shan't repeat it.

Another way to stop subsidizing displacement is to remove the incentive for landlords to displace their tenants in order to get their A. A. A. checks. I understand that Congressman Snow has introduced an amendment to the act directed to this point.

Another suggestion is that the funds available for rural rehabilitation loans be increased. At the present time, I am informed, there are 120,000 eligible applicants who are rejected by the Farm Security Administration in the States of Oklahoma, Arkansas, Kansas, Missouri, and Texas, for lack of funds. About a like number were taken care of with the funds available.

The VICE CHAIRMAN. Doctor, do you know whether that is for lack of funds or because, to a considerable degree at least, the applicants did not provide, in themselves, a fair prospect in the judgment of those who are responsible.

Dr. TAYLOR. I am informed by the administrators, Congressman, that these 120,000 applicants who were rejected were in every respect eligible.

The VICE CHAIRMAN. They just didn't have the money?

Dr. TAYLOR. The agency did not have the money to take care of the situation.

I would suggest, further, with respect to rural rehabilitation, that the level at which loans for cooperative purchase of machinery are available be elevated in order to forestall and anticipate displacement.

At the present time, in general, the practice is to give loans for cooperative purchase of machinery, and thus cut the costs of operation for the small-work farmer on the land, to make those loans after he is already in distress, perhaps displaced by tractors on other farms. I suggest that the rural rehabilitation loans for the cooperative purchase of machinery be made available to small working farmers before they are displaced, in order to anticipate and forestall it.

The VICE CHAIRMAN. Doctor, it is all right to borrow money, but they would still be owing it, wouldn't they?

Dr. TAYLOR. Well, I can't give you offhand the record of repayment of the Rural Rehabilitation clients. I am sure the representative of

that agency could tell you exactly what percentage of repayment the Government gets from the funds it makes available for that program. I understand that it is a high percentage.

Mr. O'CONNELL. May I ask a question? On that question of making funds available to these people at reasonable rates of interest, that alone would do nothing more than delay the inevitable, would it? Wouldn't you have to tie that in with other things that you have referred to, which would tend to otherwise retard the progress of the integrated interests?

Dr. TAYLOR. I am suggesting these points as part of a pattern, a program, not with the intention of implying that any single one, or even all of them together, would entirely meet the situation. I am trying to make practicable suggestions to ameliorate the situation. I think, in some respects, those loans for cooperative purchase of machinery would be permanently stabilizing, for they would keep down the overhead costs of operation, and that is an important thing in holding working people on the land against those operators who, through lower costs, might displace them.

A third point involves consideration of the funds available for purchase of land. We have now what is called the tenant-purchase program which, in view of the magnitude and urgency of this situation, should, by all means, be continued and expanded in amount and in the flexibility with which the program can be administered. That, of course, involves direct appropriations for land purchased to take care of tenants.

I think, coupled with that, we might very advantageously provide for Government insurance of private loans for purchase of land to maintain working farmers on the land, as provided, I understand, in the Lee-Jones bill, S. 1836.

The VICE CHAIRMAN. Private loans which the Government would guarantee?

Dr. TAYLOR. That's right. If the Government would extend a guaranty, we might hope for a large volume of private loans which could go into the stabilization of our working farmers on the land, which would involve no heavy outlay by Congress.

It is essentially the procedure of the Federal Housing Agency.

The VICE CHAIRMAN. In that sort of situation, the Government would permit private money to take a chance on the profit, while the Government would be taking all the chances on the loss, wouldn't it?

Dr. TAYLOR. That, of course, is true. It is correct that the Government stands in the position of guarantor, and it is to be expected that there will be some losses. It seems to me, however, that the net cost to the Public Treasury may be a good deal less, and the chance of giving momentum to this program of holding people on the land may be so much more that it would be well worth enlisting private funds, even at the cost of the guaranty.

Dr. KREPS. Certainly, if the Government is going to lose money, it would much rather subsidize small farmers remaining on the farm than increase the subsidy to large-scale farming through its present relief payments. Isn't that correct?

Dr. TAYLOR. I think so.

Another recommendation is more reclamation projects.

The VICE CHAIRMAN. You mean put more land into cultivation?

Dr. TAYLOR. I mean put more land into cultivation.

The VICE CHAIRMAN. That is interesting. We have turned out a lot of land already.

Dr. TAYLOR. I realize that. I realize the inconsistency.

The VICE CHAIRMAN. I didn't say that is inconsistent. I said it was interesting.

Dr. TAYLOR. Perhaps both. Nevertheless, I recommend that in the circumstances there be some more reclamation projects. I think it would do a good deal to hold people in an economic position in areas of the country from which many of them now are in flight.

The VICE CHAIRMAN. Why don't they do some of this migrating and turn the tide back from California? Come back to the place where they didn't have to have an irrigation project?

Dr. TAYLOR. Why don't the people go back?

The VICE CHAIRMAN. Why put in an irrigation plant and put more land in cultivation? Why not let the tide of cultivation turn back?

Dr. TAYLOR. I am sorry. I perhaps don't understand.

The VICE CHAIRMAN. I don't wonder, because I don't think I understand the question myself.

Dr. TAYLOR. Thank you.

The VICE CHAIRMAN. My question is, Why not let the population move away from those sections where it is necessary to irrigate in order to cultivate, and let them go back to the country where such necessity does not obtain, and where the land is available for cultivation?

Dr. TAYLOR. Could you make any specific suggestions as to where they could go?

The VICE CHAIRMAN. Except for just what you have indicated, yes—Texas, anywhere.

Dr. TAYLOR. Where would your people farm in Texas, under present conditions?

The VICE CHAIRMAN. On farms. There are a lot of farms. But as you say, the tenants are being run off those farms. That is the difficulty, and we have been turning out a lot of land, you know, in order for the farmers to get the advantage of the three A's, putting out of cultivation.

Dr. TAYLOR. Perhaps the reason for my suggestion is that I don't think that the other program is likely, in practice, to be sufficiently and rapidly effective.

The VICE CHAIRMAN. You see, Doctor, what I mean to say is that we have had a general policy of reducing the utilization of land that is susceptible of cultivation, and to put in these crops. We have required people to reduce their acreage, in order to get the benefit of the Government's policy. Now, then, why put in some more land, and increase the burden on the Government, when you have the land already that could be cultivated?

Dr. TAYLOR. If you could reshape our social policies to deal with mechanization—

The VICE CHAIRMAN (interposing). In other words, if we are able to have a certain number of acres under cultivation under the general policy, the more land you put under cultivation, if the policy is sound, it seems you would have to make a corresponding reduction somewhere else, and make an additional burden on the Treasury, one, the burden of putting in the reclamation project, and two, the burden of taking

out this land. I don't want to go into that now. We can think that over after we have gone to it.

Dr. TAYLOR. I see your point, Congressman.

The VICE CHAIRMAN. Let's not bother with it any more. We will take it under advisement.

Dr. TAYLOR. I would like to raise for your consideration just one more point, which is rather long range in its implications. I will make it very brief, for the time is passing.

It seems to me that in our thought we should begin to give some consideration to one or two points that we have been a little reluctant to think about. Our land policy has been based upon such acts as the homestead law, giving land in fee simple absolute to the man who settled upon it. We have believed, through a large part of our history, that that meant security and independence for the working farmer on the land.

It seems to me that it is time to raise, in our thoughts, the question. In certain situations, particularly in irrigated lands, I think the record is rather clear that it has not meant security and independence.

The suggestion I am making grows out of a statement in the President's Farm Tenancy Committee in 1937, which said, "The land policy adopted by this country under which title to practically all of the agricultural land of the Nation passed to private owners in fee simple absolute has proved defective as a means of keeping the land in the ownership of those who work it."

We have seen how, in some areas, there is a concentration of control of the operation of the land which very commonly accompanies extensive mechanization. As I say, that has been particularly conspicuous in areas where there is irrigation.

To cite a conspicuous example, the San Carlos irrigation project in Arizona irrigates about 100,000 acres of land. Under the basic laws governing land policy, the Homestead Act, the Desert Entry Act, those lands initially could be taken up only in 160-acre blocks, and that was done. Virtually all of the land passed into private ownership in the early 1900's.

Then it was found that no sooner had the land passed to private ownership than concentration of ownership began, and larger land holdings developed. Then, in the early 1920's, Congress passed an enabling act to provide for construction of Coolidge Dam. As a condition it was provided that there should be no holdings of land larger than 160 acres, again following our traditional policy. That was done in conformity with law. The water was put on the land in the middle 1920's. In hardly more than a decade, the land was all concentrated again.

The Government, through the Farm Security Administration, purchased a block of about 3,600 acres of this land, and the concentration, the type of agriculture that is developed upon it is illuminating. It illustrates the futility, under some conditions, of protecting the working farmer on the land by a device so simple as fee simple absolute ownership. I am taking the facts of my illustration from expert testimony by W. E. Packard, placed in the record of the subcommittee of the Senate Committee on Education and Labor.

The VICE CHAIRMAN. You mean, Doctor, that the Government establishes a limitation insofar as the original occupant is concerned, and leaves to him the power, then, to sell it immediately?

Dr. TAYLOR. In a few years you have the enforcement of three acts, each of them endeavoring to do it, and the last time, within a decade since the water has gone on the land, there were only nine owners of this 3,600 acres.

The VICE CHAIRMAN. In those cases, a lot of people simply go on that property, in order to get possession, and sell out. I know that is true in the ranch country in my section and I am sure that is true there.

Dr. TAYLOR. I am quite sure, in 1936, when the land was bought by the Government, there were only nine owners of the entire property. Eight of the farms were operated by tenants using hired foremen and migratory laborers. That was only one of the nine owners who was operating, and he was operating 800 acres of irrigated land, which is a great deal of land. He was living 75 miles away, and operated with hired labor. In other words, there is a story of complete absenteeism, extreme mechanization, entire use of hired labor, most of which is migratory, without settled abode. There was only one decent house on the entire project.

There were only 7 families living on the project at the time of the purchase, though on one of the properties alone as many as 35 families lived during the cotton-picking season.

We see in this example, then, the development within 10 or 12 years of a rural slum of the worst type, of the most concentrated ownership, miserable housing, manager-hired labor or operation, and virtually everything that we have regarded as undesirable in our rural way of life.

Dr. LUBIN. Would you recommend a life lease or an option to the Government to repurchase, in the sense that the Government would have to pay for such improvements as were made by the original homesteader? In other words, if he wants to sell, all he can sell is his own improvements and give the property back to the Government if he does not want to keep it?

Dr. TAYLOR. I have not given close thought to the details of dealing with this, but I am sure it is a fertile suggestion and worth consideration.

I think there are many ways, ranging in this situation all the way from Government ownership and secure leases, to protected situations such as you have described, that would ameliorate this condition and prevent it from——

The VICE CHAIRMAN (interposing). You could put a condition forcibly in the deed to run with the land, that it was never to be owned by anybody who didn't occupy the land, or any condition you want to put in.

Dr. TAYLOR. It seems to me——

The VICE CHAIRMAN (interposing). And limit the ownership.

Dr. TAYLOR. It seems to me, Congressman, there are real possibilities in modifications which will protect the working farmer.

The VICE CHAIRMAN. In other words, your reasoning is, if there is any necessity in the first instance to have a 160-acre limit, it ought to run with the title?

Dr. TAYLOR. There is some reason for the continuance. I would avoid excessive rigidities because in the course of a generation somewhat different conditions may obtain. The development of machines

which we do not now foresee, or the development of different types of culture, different crops, and so forth, might alter it so that 160 acres might not always be correct. But the assurance of—

ECONOMY OF OPERATING LARGE UNITS

The VICE CHAIRMAN (interposing). You could put a maximum on it. Doctor, let me ask you one question: Does the fact that larger ownerships make it possible better to market the product of the soil cut any figure in the advantage of bigger ownerships over little ownerships?

Dr. TAYLOR. I think that an integration, which has gone far in California, and which I described earlier, is a factor in the economy of operation by large industrialized outfits.

The VICE CHAIRMAN. You would have to have a large acreage to maintain a big processing plant that would handle your own commodities?

Dr. TAYLOR. Yes.

The VICE CHAIRMAN. And then, having got a big processing plant and a big acreage, you could probably maintain a marketing organization to give you economical distribution.

Dr. TAYLOR. Yes, I think those things work together.

The VICE CHAIRMAN. Any further questions?

Dr. ANDERSON. Mr. Chairman, Mr. Elliott, counsel for the International Harvester Co., has asked permission to make a very brief statement in counter to Dr. Taylor's difference with Mr. McCormick's testimony this morning. If it is the pleasure of the committee that he make such a statement—

The VICE CHAIRMAN. Anything to stir up a row. This meeting is getting mighty tame.

Dr. ANDERSON. This witness has not been sworn.

The VICE CHAIRMAN. Do you solemnly swear that the testimony you are about to give shall be the truth, the whole truth and nothing but the truth, so help you God?

Mr. ELLIOTT. I do.

TESTIMONY OF WILLIAM S. ELLIOTT, VICE PRESIDENT, INTERNATIONAL HARVESTER CO., CHICAGO, ILL.

Dr. ANDERSON. Mr. Elliott, I presume you refer to my quotation of Mr. McCormick's statement that the recent technological advances in farm machinery, in which the family size farm will greatly benefit, may well become a bulwark to preserve this important part of our social culture. Mr. Taylor dissented from that opinion, giving his reasons.

I take it you want to dissent from his dissent.

Mr. ELLIOTT. That is the only reason I wanted to say anything. Mr. McCormick had to leave and asked that if there was anything I thought should be added, I should do so.

Dr. Taylor has expressed the directly opposite opinion that the new farm machinery, which is much cheaper and smaller than has ever been offered before, so far from helping to preserve the small farms, is going to aggravate the movement the other way. He gave only one reason for that opinion, which was that the statements put in the record by

the Department of Agriculture, or some of their statements tended to show that the investment in farm machinery was so high that larger acreage had to be acquired by the owner to make it pay. I wanted to call attention—

The VICE CHAIRMAN (interposing). Your statement—pardon me, Mr. Elliott—as I understood it, was that it would tend toward a disposition on the part of the owner of the machinery to use it to the full capacity of that machine to operate.

Mr. ELLIOTT. That is another way of stating my same point. I wanted to call attention to the fact that all the statements put in the record yesterday by representatives of the Department of Agriculture related to the larger machinery, to the 320-acre wheat farm, the 200-acre corn farm, both of which would use a two-plow tractor or larger, and that nobody has any figures as yet on this recent development under which a farmer would buy a small tractor and a combine for less than he could buy a tractor and a binder before, I realize Mr. McCormick is expressing an opinion on an undemonstrated thing, but I think Dr. Taylor will also agree that the fact that a man with a two-plow tractor will want to enlarge his operation in order to use it to the fullest capacity, may not be true of this smaller tractor which is for farms from 50 to 100 acres.

That is an undemonstrated fact as yet.

Now, we are not alone in developing that theory. There are several—I am no agricultural economist—but there are several for whom Dr. Taylor would have the highest respect who fully agree that this small machinery development which is very recent represents an effort on the part of the manufacturers to meet the desire of the family sized farmer, not to be put out of business, but to have shorter hours and an easier life. That machinery is produced in response to his demand.

It has not been demonstrated that this is going to lead to larger acreage and it should not, because the machinery itself is adjusted for use on the single small farm.

I just wanted to say that there is no data on that yet, Dr. Taylor. I am not disagreeing with you as to the effect of the larger machinery in some places.

I should like to ask, if I may, that we might have permission to put into the record some statements of our own as to our estimates of the relative cost of horse farming and power farming.¹ We find the industry in a curious position. Mr. Johnson of the Department of Agriculture put figures in here yesterday to show that the farmer made no more money out of tractor farming than he did out of horse farming, and today Dr. Taylor shows that it is so much more economical that it is sweeping the country and will go further.

Now, it is quite possible that technological progress may produce tendencies running in different directions. The larger farm machinery, the problems of marketing, and the association of farmers who farm in California may produce one tendency. The technological advance of this small machinery may be the very thing which persuades the family-size farmer to stay there and keep on rather than go some other place.

¹ See data submitted by Mr. Elliott under date of July 9, 1940, which appears in the appendix on p. 17597.

I do not think we are going to keep him there by depriving him of the benefits of technology and by telling him, "Your job is to work 16 hours a day, with a back-breaking job."

I think the whole tendency of making his hours shorter and giving him some of the benefits which other parts of our population are getting, is going to make it a more livable life which he will try to preserve.

The VICE CHAIRMAN. But anyway, it seems to be fairly reasonable that you probably wouldn't make the machine unless there was somebody who wanted to buy it? I mean, that is fairly reasonable.

Mr. ELLIOTT. We think the farmers know 50,000,000 Frenchmen can't be wrong. The farmers know perhaps more than some other people [laughter] about what they save by buying that machinery, and we are asking permission to put in tables here of actual farm operations.

The VICE CHAIRMAN. Do those tables show whether he is getting lazier or greedier?

Mr. ELLIOTT. Well, I don't know whether you would say that, Mr. Chairman. We don't call our laborers, our factory laborers, lazier because they now have a 40-hour week instead of a 50, and I don't believe anyone in this room would deny the right of the farmer to get his hours shortened, if it can possibly be done without bad social effects; and in itself, it is a good social effect.

The VICE CHAIRMAN. We understand, and I think the committee can appreciate the strength of the points. In other words, if you can make life on the farm easier, you have a greater tendency to hold the farm boy on the farm than to go to town and work in a job where it is more mechanized. There are many different aspects to the thing.

Now, Dr. Taylor—and this may be off the record.

(Off the record.)

Do you want to say anything further, Dr. Taylor?

Dr. TAYLOR. Well, Dr. Anderson invited me to return to the stand and I would like to say just one or two things.

The VICE CHAIRMAN. Well, go ahead.

Dr. TAYLOR. As a man who has husked corn and plowed corn with a walking plow behind a team of mules, I am fully appreciative of what the manufacturers of machinery are doing, to make labor less arduous.

I think the farmers sense their economic increase pretty well when they buy the machines. I think that that is the driving force behind the social and economic effects on others, of which I am so apprehensive. So I recognize the force and do not deny the fact that the farmers buy the tractors and other machines because it is good for them to do so.

The VICE CHAIRMAN. Well, now, that looks like a pretty good quitting point, doesn't it? Let's quit.

Dr. TAYLOR. May I add just one more thing? May I end on a note of harmony also?

There are ways of holding working farmers on the land, as we have discussed a few moments ago, a variety of ways, and one form of doing that, to which I think we should give more consideration than we have been disposed to give it in the past, is the cooperative farm.

There are a number of cooperative farms in the country and we are beginning to get records on them. I am going to cite only one, not to

generalize or say that the records of all of them are of that kind, but to indicate that they seem to be worthy of very serious consideration.

In San Joaquin Valley, where we recently had so much trouble that the Senate came out to look us over, the agricultural employers felt so aggrieved and so just in their cause that they felt, in their own words, it was necessary to take rubber hose and fan belts to drive striking cotton pickers out of the city park of Madera. (I am quoting now from the record of the Senate committee.)¹

Very close to that same area, we have a cooperative farm. The cotton strikers last fall were asking for more than 80 cents a hundred, which is what the agricultural employers felt was all, in justice, they could afford to pay and all that they should pay.

Two counties away was this cooperative farm, operated by the Government. The 15 families on that farm (this I draw from the records of the Senate committee also, the testimony of Mr. Packard),² these 15 families made their monthly wages as participants in the farm. Out of the profits of the year's operation, after meeting all of their obligations to the Government and to everyone else, they put aside \$500, approximately, in an educational fund, and \$2,500 in a reserve fund in order to finance their operations the next year independently of the banks. In addition to that, they allocated \$1,200 to pay the cotton pickers, who were employees and not members of the cooperative and whom they had already paid 90 cents, \$1, or even more, when the agricultural employers felt that they could not pay more than 90 cents.

Having paid them 90 cents, \$1 and even more, for 100 pounds of cotton picked, they allocated from their profits something like \$1,200 for distribution among 201 cotton pickers as a bonus. The amounts ranged from, I believe, 7 cents to \$55.

It seems to me evidence of that kind suggests that in our effort to hold working farmers securely on the land, we should give more attention to the possibilities of doing it through cooperation, than we have given in the past.

Dr. ANDERSON. The last three charts in Dr. Taylor's brief will be admitted to the record.

(The charts referred to were marked "Exhibits Nos. 2689 to 2691" and are included in the appendix on pp. 17456 and 17457-17458.)

The VICE CHAIRMAN. I am afraid we are going to have to adjourn. We are very much obliged to you.

We stand adjourned until 10:30 tomorrow morning.

(Whereupon, at 5:45 o'clock, the hearing adjourned until 10:30 in the morning of the following day, April 25, 1940.)

¹ See hearings before the subcommittee of the United States Senate Committee on Education and Labor, Part 51, p. 18685.

INVESTIGATION OF CONCENTRATION OF ECONOMIC POWER

THURSDAY, APRIL 25, 1940

UNITED STATES SENATE,
TEMPORARY NATIONAL ECONOMIC COMMITTEE,
Washington, D. C.

The committee met at 10:40 a. m., pursuant to adjournment on Wednesday, April 24, 1940, in the Caucus Room, Senate Office Building, Senator William H. King, of Utah, presiding.

Present: Senators King (acting chairman), and O'Mahoney (chairman); Representative Williams; Messrs. Kades, O'Connell, Berge, Pike, Lubin, Kreps, and Brackett.

Present also: William T. Chantland, Federal Trade Commission; S. Abbot Maginnis, Department of Justice; and Dewey Anderson, economic consultant to the committee.

Acting Chairman KING. The committee will be in order. Call your first witness.

Dr. ANDERSON. Some 3 weeks ago we started these hearings with an over-all view of the situation presented by Dr. Kreps and Mr. Watson Davis, who reviewed what was occurring in the field of industry and agriculture with respect to scientific and technological advance, and pointed out some of the problems which confront us, in an attempt to solve this unemployment situation. In the last 2 weeks we have presented a whole series of what amounted to case studies of the situation.

Today we propose to examine what can be done about this big problem of training and placing and retraining and replacing the labor force of the Nation. We have assembled a panel of witnesses, each expert in a particular field. They are educational men and applied educational or vocational-educational experts, whose business it is to deal realistically with the training and placement of the youth and the adult population of the Nation.

Each member of the panel will speak on a particular phase of the topic. The first witness will be Dr. John K. Norton, formerly head of the division of research of the National Education Association here in Washington for many years, and for several years now professor of education and an expert in the field of educational finance and school support at Teachers College, Columbia University.

Acting Chairman KING. That is not the City College that Bertrand Russell wanted to be connected with?

Dr. ANDERSON. No; it is not.

The second witness in the panel is Dr. Harold F. Clark, an economist who is now professor of economics at the same university. The third witness is Dr. J. C. Wright, Assistant Commissioner in charge of Vocational Education of the United States Office of Education. The fourth witness will be Dr. William G. Carr, executive secretary of the Educa-

tional Policies Commission and research director of the National Education Association. We hope to follow through with this panel today.

We do have, however, a witness who was not able to come at his scheduled time, Mr. William Green, who will appear this afternoon. It may be necessary, therefore, to carry some of today's witnesses over to tomorrow.

Acting Chairman KING. By that you mean that Mr. Green may not be called?

Dr. ANDERSON. Mr. Green will be called in any case as the first witness this afternoon, after lunch.

(Senator O'Mahoney assumed the Chair.)

Dr. ANDERSON. Our first witness, then, this morning, in this discussion of education and its influences in placing the labor force and raising the economy to a prosperity level, is Dr. John K. Norton, whom we will ask to come to the stand at this time.

Before Dr. Norton is sworn, Mr. Chairman, the Educational Policies Commission, a commission of professional and lay people brought together under the auspices of the National Education Association to study the problem of education in a democracy and the relationships of education to recovery, has prepared and presented to us a series of charts which are pertinent to the discussion of the day. I would ask that they be accepted as exhibits, as they are basic material for our study.

The CHAIRMAN. You want them entered in the record?

Dr. ANDERSON. That is right.

The CHAIRMAN. Without objection, it is so ordered.

(The charts referred to were marked "Exhibits Nos. 2692 to 2718" and are included in the appendix on pp. 17459-17485.)

Senator KING. May I make one inquiry before you start? Do you intend to discuss the question of education for—what shall I say?—farming and for irrigation and for land development, or is it merely an intellectual excursion we are going to enter upon this morning?

Dr. ANDERSON. I am glad you asked the question. I believe these men are something extraordinary in the field of educators, in that they will hew to the practical line all the way through. One of the witnesses will deal specifically with the matter of vocational education of an applied kind, the training of young and old so that they can do the work of the workaday world.

Mr. Chairman, Dr. John K. Norton, professor of education of Teachers College, the first witness, is ready to be sworn.

The CHAIRMAN. Do you solemnly swear the testimony you are about to give in this proceeding shall be the truth, the whole truth, and nothing but the truth, so help you God?

Dr. NORTON. I do.

**TESTIMONY OF DR. JOHN K. NORTON, PROFESSOR OF EDUCATION,
TEACHERS COLLEGE, COLUMBIA UNIVERSITY, NEW YORK,
N. Y.**

Dr. ANDERSON. Dr. Norton, you are professor of education of Teachers College at Columbia University?

Dr. NORTON. Yes.

Dr. ANDERSON. How long have you been professor of education?

Dr. NORTON. A little over 10 years.

Dr. ANDERSON. What is your specific field of study and teaching?

Dr. NORTON. Educational administration and educational finance.

Dr. ANDERSON. You have published books in the field of finance?

Dr. NORTON. Yes; such things as *Wealth, Children, and Education*.⁵ and other things.

Dr. ANDERSON. You are also a member of the Educational Policies Commission?

Dr. NORTON. Yes.

Dr. ANDERSON. And as such are responsible for the writing and publishing of this very recent work, *Education and Economic Well-Being in American Democracy*?²

Dr. NORTON. Yes; with the cooperation of other members of the Commission, economists, and other people.

Dr. ANDERSON. This is one of the basic studies being made by educators and economists?

Dr. NORTON. It is one of the 4 major reports issued by the Educational Policies Commission to date.

Dr. ANDERSON. I think the committee has been supplied with copies of this volume, and I hope they have had time to review it.

The CHAIRMAN. The members of the committee have not yet received copies of it, nor have they received copies of the charts. I think they are on the way up.

Dr. ANDERSON. The material you are presenting is on the subject of education and economic well-being, and I take it you are laying the groundwork for the discussion that will follow during the day?

Dr. NORTON. That is true, although I will particularly focus my remarks on the relationship of education to production and productivity.

Dr. ANDERSON. Would you proceed?

Dr. NORTON. Mr. Chairman, members of the committee, the Educational Policies Commission recently issued a report dealing with the interrelations of education and economic well-being. In preparing this document, the Commission sought the counsel of economists, educators, and other competent scholars. The technical literature of economics, education, and other fields pertinent to the investigation was carefully examined. As a result of this work, which extended for a period of several years, we are in a better position than ever before to attempt the difficult task of assessing the relationship of education and economic well-being.

POTENTIAL PRODUCTION OF THE UNITED STATES

Dr. NORTON. I will begin by pointing out that one of the striking features in the development of the United States has been the enormous increase in its production, both actual and potential. When the Nation was founded, it had an annual current income of some \$677,000,000; that is, total income, social income, of all the people, less than \$1,000,000,000. Now it receives a yearly income which, even in years of limited prosperity, runs somewhere between \$60,000,000,000 and \$70,000,000,000, and which in prosperous years is between \$80,000,-

¹ John K. and Mary A. Norton, *Wealth, Children, and Education*, New York, 1938.

² Educational Policies Commission, *Education and Economic Well-Being in American Democracy*, Washington, D. C., 1940.

000,000 and \$90,000,000,000. Furthermore, competent researches by the Brookings Institution group and others have demonstrated that without expanding existing plant and resources the national income could be increased more than \$15,000,000,000 above even the most prosperous years.

Now, I recognize clearly that the problem of realizing that potential productivity is an exceedingly difficult and complex one, and I have come here to offer no quick and easy panaceas for taking care of that problem.

I rather am interested in analyzing one element which doubtless will be, must be, in the picture when the problem is met. I refer to education.

Per capita production and per capita income increased several fold during the past century in nations like Great Britain and the United States. During the last 70 years population in the United States increased threefold, while the physical volume of goods produced and consumed increased more than ninefold.

The CHAIRMAN. What is the authority for that statement?

Dr. NORTON. Investigations of the Twentieth Century Fund in one of their recent publications, and other sources.

The CHAIRMAN. The Twentieth Century Fund staff made an analysis of authentic figures?

Dr. NORTON. A competent staff of economists and other experts.

The CHAIRMAN. So that this conclusion is drawn from those figures which are taken from authentic statistics?

Dr. NORTON. I believe that they are drawn from absolutely reliable statistics properly interpreted, yes.

A primary factor in this phenomenal expansion of productivity has been the application of science, invention, and the power-driven machine, and that whole complex of forces we sometimes call technology, to the processes of agricultural and industrial production. Education, and here is where we get down to our topic more directly, is also in the picture. The purpose of this statement is to examine the relation of education to increasing production and increasing productivity.

If you will examine economic literature you will find that economists generally recognize four basic factors in the productive process. These are labor, the human factor, natural resources, capital, and management. A properly planned and administered system of education makes one of its greatest contributions to economic well-being because of its effect on the first of these—namely, labor. In the United States this contribution has been exercised through various means, and I would like briefly to point out some of those in outline form as a basis for further discussion.

First, and I put this first one advisedly, the development of an open-door policy in education, we might say the American way in education, served as a driving influence throughout our history to encourage each individual to rise through his own efforts. As Thomas Nixon Carver, well known economist, has said:

The greatest stimulus that can be given to the human spirit is to serve notice upon it that its achievements are to be limited solely by its own native power, * * * that neither birth nor family prestige will count for much, and that humble birth and lack of prestige are no handicap to the person of ability and industry. This has made the typical American a model of energy. Our public school system has provided him a free chance to train whatever native ability he possesses.

We have done that in education at least to a degree. We need to do it more effectively in the future, but we have done it to a degree that has made education an important factor in developing individual initiative.

With the passing of each decade, graduation from high school and even more extended schooling are prerequisite to admission to a growing percentage of occupations. My point here is that actual formal schooling, the ability to answer "Yes" when an employer asks you whether you are a graduate from a high school, in the practical workaday world—and one could give many illustrations of this—is becoming a prerequisite to employment.

In some industries that one is surprised to hear about they are even calling for college graduation.

Energy and graduation from the "school of hard knocks" no longer promise success in most callings. Maybe in some the exceptional individual may get by with graduation from the "school of hard knocks," but not for the rank and file. Opportunity more and more lies along the route of extensive general education and specific vocational or professional training. The doors of educational opportunity must be wider than ever before if all Americans are to feel that no insuperable obstacles prevent the individual from realizing the best that is in him. Such a feeling must prevail if the dynamic economic effects of education are to be continued.

If you are interested in future evidence to support that whole general thesis, we would be glad to come back to it later.

Senator KING. May I interrupt you?

Dr. NORTON. Yes.

Senator KING. Have you elaborated upon the views expressed by Herbert Spencer in his great work in education and other classical writers of that period, one or two from Germany?

Dr. NORTON. You refer to such things as education's worth?

Senator KING. In part; yes. Of course, I wouldn't want to confine it to a materialistic education; there must always be the moral and spiritual, a factor which, after all, is basic in any proper education, but Herbert Spencer devoted some of his great ability to the elaboration of what education is——

Dr. NORTON. Yes.

Senator KING (continuing). What it must do, and he discusses the various spheres of activity in which the human being may operate. I was wondering if back of your thesis and the views of those with whom you are associated, the exposition made by Spencer has any recognition.

Dr. NORTON. I would say yes. In fact, almost any fundamental idea if you trace it to its roots often goes back a great many years or centuries, even. If you take material of the type that Spencer issued, and *The Wealth of Nations*, of Adam Smith, who a century or more ago pronounced in these areas, and add to that the experience of a century (they were hypotheses when they stated them), I think we have a right to say that many of those ideas now have to a considerable degree been proved in the practical laboratory of social development.

Second, education has increased productivity by directly or indirectly contributing to the occupational efficiency of the individual worker. As the number and proportion of unskilled laborers have de-

clined, the number and proportion of semiskilled, skilled, and technically trained workers has increased. In fact, the economic growth of the United States may be epitomized in the fact that a growing percentage of trained workers have used more and more effective methods of work. I would emphasize both of those, trained workers using more effective methods of work, as responsible for the tremendous increase in productivity that has occurred in the industrial revolution.

Mr. O'CONNELL. When you speak of trained workers you are using that phrase, I take it, as meaning skilled in doing a particular job?

Dr. NORTON. I am using it in a very broad sense, here meaning everything from professional workers to semiskilled workers.

Mr. O'CONNELL. Would it have the same significance as the old skilled worker, meaning a craftsman or master mechanic? I have in mind that we have had a substantial amount of testimony here by other witnesses to the effect that mechanization resulted in—the word used I think was “degrading” the quality of the worker in that the type of training that was required was something that could be acquired in a period of maybe 30 days, and while they were in a sense highly trained workers they were not comparable to the old skilled mechanic at all. I was curious to know on what basis you came to the conclusion that the number and proportion of semiskilled, skilled, and technically trained workers has increased. It seemed to me that it might be that you would construe all the people on a production line in an automobile factory as technically trained workers and yet not skilled in the old traditional sense.

Dr. NORTON. I am referring to evidence such as is presented on pages 84, 85, and 86 of this report, and I would say further that—

The CHAIRMAN (interposing). You are referring to the report of the Educational Policies Commission?

INCREASE IN OCCUPATIONAL TRAINING

Dr. NORTON. Yes; in which we cite a number of scientific investigations. In discussing the general trend of that evidence I would say that it is very important, as you have indicated, to define what area of occupations you are discussing. First, dealing with the area that we call manufacturing, in which the highest degree or percentage of the automatic machine has come into the picture, I tried to find every investigation on that subject that had been made, and after looking them all up and very carefully reviewing the evidence, I think it is fair to say that it is inconclusive. Some investigators say that even in manufacturing the total amount of training must be more, if you consider all workers, than it was a decade or 2 or 3 decades ago. Some say that it is not as much. Quite frankly, when you consider all investigations it is inconclusive if you think only of the field of manufacture. But please have in mind that workers in manufacturing constitute a minor fraction of all workers, and a declining proportion of all workers. Now, if you will direct your attention away from mechanized industry to occupations as a whole, the evidence there is quite clear and definite that the total amount of training per worker on the average is definitely increasing, and from all reasonable interpretation of present trends it is going to continue in the future. So it is very important to distinguish between one segment of occupational life, manufacturing,

and all occupational life involving everything from the professions down.

Mr. O'CONNELL. By training you mean training which is rather directly connected with the particular work that the man does as distinguished from general education?

Dr. NORTON. Yes; although you can leave general education out of the picture altogether. My emphasis here is on what we should call direct occupational training.

The most immediate and apparent economic outcome of education is where it provides specific training for a trade or profession, which you were just asking about. The objective here is to give each worker the general and the specific training which will permit him to work, in whatever occupation he may find himself, in an intelligent and efficient manner. Such training may be provided through a variety of agencies—trade schools, public or private, as well as industry itself, or labor may be in the picture. The important factor, however, is that the provision of such training has positive economic effects. There is complete agreement on this among economists. I quote one:

Without education one is likely to be limited to unskilled occupations. With education he is able to find more remunerative employment. The general effect of more widespread schooling is to increase the ranks of skilled workmen and to decrease the number of people capable only of cruder manual work.

A series of factors are now operating in American life which make carefully planned and effectively organized occupational training of first importance. The decline in immigration has largely cut off our supply of skilled workers from Europe, and it happens that many of them who came here 2, 3, and 4 decades ago are beginning to reach the age of retirement. The percentage of occupations in which definite training is either desirable or imperative is increasing. I am referring now to occupations as a whole. It seems probable that education can and should make increasing contributions to productivity in the future through expanding and perfecting its training of youths for occupational efficiency. I would emphasize that point of perfecting its training. I think in many respects, as in other areas of life, we have fallen considerably short of the ideal of doing what we should, so I am not arguing for just more of the same kind of education we have had in the past; I would rather urge that we need more of a different kind of education. In this publication that has already been brought to your attention, you will find two chapters right near the front of the book and two very important chapters dealing with the kind of general education for economic well-being. Dr. Carr, one of the later witnesses, is going to deal with that particularly, and Dr. Wright will be particularly concerned with another chapter, Kind of Occupational Education for Economic Well Being.

However, it is important that education to increase efficiency of labor should not be conceived in narrow terms. The effective operation of enormous aggregations of labor and capital, characteristic of contemporary economy, demands high types of vocational and economic intelligence. I am referring there both to occupational and general education. Improved organization and industrial techniques can be the outgrowth of suggestion and initiative on the part of the rank and file worker, as well as the product of research and managerial ingenuity.

The general pattern of organization in a business enterprise is likely to be different, as well as more efficient, when the manager is able to assume a degree of judgment and initiative on the part of the worker, as opposed to the ability merely to follow simple directions in a routine manner. That was brought very strikingly to my attention repeatedly on a little journey that took me through the Orient here 2 or 3 years ago, in which I visited mills in Indian and China and talked with managers and talked with them particularly as to the problem that is involved in the fact that the typical worker they have to deal with has little education. Even in mechanized plants such as cotton mills—they emphasize that what they can do even in that highly mechanized process is very much conditioned by the general economic and educational background of their workers. One gets a much clearer picture of some of these things that we take for granted in our country when one goes to countries in which the general level of education is not so high.

One industrial leader from a background of practical experience in directing a large business organization has stated :

* * * the effectiveness of individual capacity to produce, or to manage production, is determined by the degree of social cooperation, and that this cooperation depends primarily upon education * * *

I am quoting from Chester I. Barnard, as you notice.

High productive efficiency is impossible without widespread education. This is not simply a matter of securing leaders in science, invention, industrial organization, statecraft, etc., by an educational screening of the masses. No greater error could be made, it seems to me, than to adopt the notion too commonly held that either political or economic effectiveness is chiefly a matter of leadership. When generals can find no colonels, they must become mere captains. Captains are limited by the character, spirit, and ability of the men they command. The intensive training given to recruits is significant.

Now a third area. Education increases productivity by promoting occupational mobility. It is an accepted tenet of economics (and this idea occurs over and over again in standard economic literature) that the ability of labor to secure the training needed to transfer from crowded and low-paid occupations to those less crowded and better-paid tends to increase the national income. It is simply that if the individual worker on the average is working with greater skill and is producing more, by definition the national income is increased. When workers of energy and capacity must continue in low-paid common labor because of inability to secure training requisite to entering higher-paid callings, the national income tends to be decreased.

Occupational mobility is of increasing importance in a dynamic economy in which new discoveries are continually creating new vocations, many of which involve technical training. Education in the past has assisted in thinning out the overcrowded ranks of unskilled labor by increasing the proportion of workers in skilled and professional occupations. Its contribution in this area in the future should and can be made more effective. There is a whole series of ways in which that can be more effective. We give them in this publication, such matters as the collection of much more significant and definitive data as to what the occupational trends are, so that vocational advice which is pertinent can be given to high school youths, information as to the kind of training which is required, so that the kind of training

given in the school will be that which it can give best, leaving it to other agencies to give the training that can be given best by other agencies.

POSSIBILITY OF DISCRIMINATION IN VOCATIONAL TRAINING

The CHAIRMAN. The objection has been made in the past to vocational training, particularly for mechanical and industrial pursuits, that it would tend to limit the opportunities for advancement of those who take the vocational training rather than broader training in what in the old days used to be called the humanities.

Dr. NORTON. I don't believe you can speak in easy generalities in dealing with that problem. I begin by saying that every citizen, if you are going to assume a democratic order, needs a certain amount of general citizenship training, and he needs that particularly in the economic realm. We have just eliminated from the census the question about illiteracy because education has pretty well conquered the problem of what we call alphabetical illiteracy. I would say we still have the great problem of conquering what we call economic illiteracy. That applies to all workers. When you go beyond that and get into the more specific vocational or occupational training, I don't believe you can generalize too easily.

The CHAIRMAN. Well, does vocational training, vocational education, tend to differentiate youth into classes according to the economic standards of the parents?

Dr. NORTON. It should not if there is proper vocational guidance, because the area into which a youth goes should rest upon, first, knowledge of the various areas in which he might go, factual information, and, second, knowledge of his capacity and aptitudes and industry and all of those things.

The CHAIRMAN. You started out by quoting from Thomas Nixon Carver.

Dr. NORTON. Yes.

The CHAIRMAN (continuing):

That neither birth nor family prestige will count for much, and that humble birth and lack of prestige are no handicap to the person of ability and energy.

Now, I take it that you quoted that statement from Carver with entire approval.

Dr. NORTON. I did.

The CHAIRMAN. It still remains the general desire of all American educators—

Dr. NORTON (interposing). The ideal.

The CHAIRMAN. But do you not tend to divert from the ideal when you undertake to establish a different kind of education for different kinds of children?

Dr. NORTON. No; I don't believe—

The CHAIRMAN (interposing). And how are you going to determine the kind of children which should take this particular training of which you speak?

Dr. NORTON. I would say first generally that I do not believe that there is anything undemocratic in the principle of differentiation, that is having different kinds of education. Now it is true that in the field of general education up to a considerable level, up to a

relatively high level, limited only by capacity and such factors, we should have the same kind of education, the same general cultural background, but along about the end of high school, maybe before, certainly not very much after (it depends on the individual), there should be pretty careful assessment of the vocational opportunities of the country and the capacities and diligence and all that of the individual child, and out of that should come the best possible guess as to where he will achieve greatest success. Please don't misunderstand me. I do not mean I would have any board say, "You have to go this way." That is not what I am arguing for. I am rather saying that you should put in the possession of the parents of a child and of the youth himself by the time he has reached 17, 18, or 19 years of age, the information on which he can make an intelligent choice himself. Now we have done that to a very limited extent.

We should do it far more, and I would say that to the extent that you do that you encourage each person to rise through his own energy through the areas of work where he is most likely to rise.

The CHAIRMAN. Then your idea is that the preliminary education and high-school education should all be upon the highest cultural basis and for all children alike. That is, the public-school system should be so arranged that all children in the community should receive the same high cultural training, the very best that the community can afford.

Dr. NORTON. And I would go further and say also the very best occupational training for them.

The CHAIRMAN. Yes; but I was leading now to the point of the introduction of the vocational training. As I understand your statement now, it is that that vocational training should not be imposed upon youth, but should be opened as an opportunity to him after this cultural training for all has been completed.

Dr. NORTON. No; I wouldn't cut it off that way.

The CHAIRMAN. I didn't intend to imply that it was being cut off.

Dr. NORTON. They would run parallel. You would begin prevocational education, some thinking about what they were going to do in vocation, perhaps even as early as 13 or 14 or 15 years of age. You begin the actual vocational education at age 16, 17, 18, depending upon where the youth was going and his capacity, and certainly all would, by the time they were through high school, have some kind of an idea of the general route they were taking.

The CHAIRMAN. In any event, the choice would lie with the student and not with the school board or the school master or whatever.

Dr. NORTON. I would say in our society, in a democratic society, the final decision would rest with the student and his parents.

The CHAIRMAN. Now, that is a qualification. You say, "the final decision." What preliminary decision would not rest with them?

Dr. NORTON. I wouldn't say that things would be called preliminary decisions; I would say that the function of the school is to collect the most accurate, unbiased data bearing on the whole situation, both occupations and his capacity, honestly interpret them, and then try to show him exactly where the best opportunities are for him, with the hope that he will make the proper choice. In most cases where we have better developed programs they do take the proper choice. I suppose sometimes mistakes are made, human beings always make

some mistakes, but in the long run there will be far fewer than if we give them no information and have a situation such as exists in some places today.

The CHAIRMAN. In any event, you want to preserve complete freedom of choice on the part of every student.

Dr. NORTON. Yes.

The CHAIRMAN. So that there will be no measuring of the quality and kind of education by the economic level of the parents.

Dr. NORTON. Right, or putting it negatively, I would certainly not want to make any change in the school system that would be in the direction of making it a class-school system, the type that they have had in Europe, and still have in some places.

Senator KING. Dr. Norton, in your very interesting, instructive presentation thus far you have frequently used the word "cultural," cultural teaching, cultural education. What definition do you give to the word "cultural"?

Dr. NORTON. Well, perhaps a better term, one that is used more in education, would be general education. By general education I mean preparation for all of those responsibilities of citizenship, both individual and group, which lie out of the field of specific training for a vocation or occupation.

Senator KING. You would not exclude the preparation for farmers or blacksmiths or persons engaged in various manual pursuits?

Dr. NORTON. No; I would say that those parts of our population, just as all parts of our population, should have full opportunity for cultural or general education as well as for vocational education.

Senator KING. Do you think that the educational trend is toward—I don't use the term offensively, of course—the white-collar profession or the white-collar class, with a growing disposition to avoid manual labor, the manufacture of furniture, the manufacture of beautiful things with the hands, as our fathers and our forefathers did? I remember in my State we had some fine English cabinet workers who built a great organ, one of the finest in the world; they didn't have the machinery they have these days. We had men there who would make the finest violins, and their skill and technic was great, they had been taught that from youth—men who made the finest tables and furniture that would be an ornament a thousand years from now. I was wondering if we are not drifting away from the concept that labor by hand is honorable and involves cultural development and appreciation of the fine cultural things of life.

INCREASED EMPHASIS ON SKILLS

Dr. NORTON. If you put it on the basis of what is the trend, I do not think the trend is in that direction. I might admit that in the past, due to a series of factors which we won't review now, there has been that emphasis in many schools. I think the trend is away from that emphasis. For example, I spent a day in one of the well-developed vocational high schools of Pittsburgh recently. I happen to be associated with a general school survey that is going on there now. You can go into those high schools in Pittsburgh and you find them getting the foundation training that leads in the directions that you were specifying. They are gaining respect for skilled work of the manual type.

Now, if you had gone into Pittsburgh 30 or 40 years ago, or when I went to school, you wouldn't have found that type of thing. Those schools have all come in, or nearly all of them, within the last generation. I would say the trend is very much in the direction of giving respect for and training for what you would call highly skilled callings.

Professor Taussig deals with the whole thing that we have been discussing in a very beautiful sentence because it is so sweeping and yet I believe is so fundamental:

The removal of all artificial barriers to choice of occupation is the most important goal of society.

In addition to the quantity and quality of its labor supply, the natural resources of a nation constitute another basic factor affecting productivity. The lack of foresight in America's wasteful depletion of natural resources is an outcome of their plenitude. Other peoples have gained from experience the lesson which the United States is just beginning to learn.

Schools and colleges have already made substantial contributions to the conservation of natural resources. Schools and extension services are teaching farmers the importance of contour farming, crop rotation, soil fertilization, and protection of forests. Dr. Wright, when he comes on this afternoon, can give you many more details on this area. Colleges and universities are conducting research and imparting technical knowledge to agricultural and chemical engineers, business executives, and other experts.

Further contributions of education in conserving our heritage of physical resources should be made in directions already begun. There should be increased appreciation of the fortunate position of the United States with reference to resources. I don't believe many of us realize just how fortunate we are to have taken possession of a continent with none of its resources depleted as we did a few centuries ago. We have but 6.2 percent of the world's population, but we produce and consume some 50 percent of the world's mechanical energy. The United States ranks first among world powers as to national self-sufficiency in iron ore, coal, petroleum, copper, lead, sulphur, aluminum, zinc, phosphates, and other strategic resources.

We ought to understand the significance of that position. Education for conservation of the right kind emphasizes wise and economic use, not only conservation but wise and economic use of natural resources and develops vigorous public disapproval of flagrant waste whenever it exists. If you will go to the courses of study that are being developed in our high schools, you will find that this is coming in as a subject of specific and authoritative study, and I would say that there is no place where education can make a more fundamental contribution to preserving our economic foundations in the field of production than in this realm.

Capital is a third basic element in production. Here we are concerned with tools, machinery, plants, and technical processes employed in transforming materials into consumer goods. Science and technology are involved since they play a major role in discovering the tools and technical processes which give capital its peculiar modern characteristics.

Colleges and universities have conducted much of the significant research resulting in basic modifications in technics of production and

designs of machines and equipment. Research in the field of agriculture has perhaps been the most continuous and effective, going back, as you know, to the establishment of the land-grant colleges in 1862. Investigations concerning agricultural and biological chemistry, soils and soil fertility, field crops, horticulture, animal husbandry, and many other areas have been a major factor in remaking agriculture in the United States during the past two or three generations; and if you could compare the intelligence with which the farmer approaches agricultural problems with those used by the farmer in some of the other parts of the world, we would realize what a great asset we have here.

The research of scientific workers in universities has resulted in discoveries on which many new industries have been founded. This is but one of many illustrations of the important effect of university research in founding new industries.

Karl Compton says:

Eighteen of the new industries which have grown directly out of scientific research within the past 50 years provide one-fourth of all the employment in the United States. The majority of the products now manufactured by electrical companies were unknown 15 years ago. It is estimated that 95 percent of our chemical industry (which as you know in the last two or three decades has become a basic industry in this country) is based on fundamental discoveries made in university laboratories.

Nearly 200 college laboratories are used not only for the purpose of instruction but also to a considerable extent for industrial research work and commercial testing. The proved economic value of university research is one of the factors which has influenced industry to establish commercial research laboratories, involving expenditures of \$100,000,000 annually.

A fourth factor in this whole complex is management. The size and complexity of business concerns, the number of employees involved, the range of raw materials consumed, and the amount and types of capital equipment employed give a social significance to executive decisions and demand a grasp of technical knowledge and principles of organization which transcend those required of entrepreneurs in earlier economics.

Schools have long provided literacy and other elementary education which the self-made man has possessed. The tendency recently has been to emphasize the importance of formal training as a qualification for leadership in business enterprises. Colleges, technical schools, and universities train scientists, engineers, and technologists who provide expert knowledge for the business executive and who in some cases themselves assume managerial positions. Graduate schools of business are training growing numbers of young men, who first enter minor executive positions from which they are recruited to those involving more managerial responsibility.

Now we are coming to another subject—how does this theory that education affects productivity at these various vital points work out in practice? A number of studies have attempted statistical measurement of the relationship of productivity and provision for education among the 48 States of the Union. One of the most comprehensive and careful of these was made several years ago by Bowyer, and this is merely illustrative. It attempted to compare the percentage of its wealth which a State spends for schools with the rate of increase

in its wealth during the subsequent 25 years. This study found that "in those States in which the percentage of wealth expended for public schools in 1890, 1900, and 1912 was the greatest, the increase in the average per capita wealth during the following periods was larger than the corresponding increase in States which had provided adequately for their schools."

We can approach this problem also from the negative side, as Odum has done in some of his investigations. He shows that "the Southeast excels in the two primary resources—namely, natural wealth, natural resources—and human wealth, while it lags in the secondary resources of technology, artificial wealth, and institutional services," such as education. One of the outcomes of these lags is the wasted, as he calls it, "possibilities of youth undeveloped and untrained, born, living, and moving through life without ever gaining a knowledge of their power and possibilities." The outstanding fact in this whole situation, he says, seems to be that of "undeveloped possibilities and of human waste."

POTENTIALITIES OF DOMESTIC CONSUMPTION

Dr. NORTON. One calculation was made recently as to what the effect would be on our market for goods if the States in the lower half with reference to income per capita were lifted to the average for the country as a whole, and the conclusion was reached that the effect in terms of creating a new market would be far greater than our whole foreign trade. In other words, we have the possibility of developing within our own boundaries, by bringing areas that have not advanced as rapidly economically as others up to the average, a market for goods, opportunity for trade, which is far more important than we get from all of our foreign trade.

It appears, then, that logical analysis of economics, involving more than a century of study, the experience of the nations of the world, and the findings of technical statistical investigations, unite in supporting the hypothesis that high productivity and adequate education go together and that the latter does have important effects on the former.

The CHAIRMAN. May I interrupt? To return to what you were saying just a moment ago, by whom was this conclusion reached that a much larger market would be opened by raising the capacity or ability to consume of the lower income States?

Dr. NORTON. It is based on certain data that I took from certain economic sources.

The CHAIRMAN. I think it is a perfectly obvious conclusion.

Dr. NORTON. It is obvious, but it is very striking when you get the facts.

The CHAIRMAN. Your statement was that the conclusion was reached. I would like to get some additional authority.

Dr. NORTON. I can personally send you some of the data on that, if you would like to have it.

The CHAIRMAN. Can't you state for the record some additional authority on it? I think it is a perfectly clear statement that nobody could disagree with in the facts that are presented.

Dr. NORTON. Yes.

The CHAIRMAN. I have frequently thought that many of us pay too little attention to the open door at home, as I think Professor Beard once referred to it.

Dr. NORTON. Yes.

The CHAIRMAN. We are spending too much time thinking about potential markets that are not so easily reached. I was very much impressed about 2 years ago by seeing a 2-page colored map of the United States in the Saturday Evening Post prepared by the advertising division of the Saturday Evening Post. This map undertook to designate the comparative value as markets of every county in the United States. It illustrated that business was national in the first place.

Dr. NORTON. Right.

The CHAIRMAN. It was an appeal to national advertisers in the *Saturday Evening Post* to distribute their wares in counties which had the highest purchasing capacity, but it was perfectly obvious that if those counties which were represented in the color that told of the lowest purchasing capacity could be raised to the other level there would be a tremendously increased market for all of the *Saturday Evening Post* advertisers.

Dr. NORTON. And I would emphasize the importance of looking to that market and of using measures, of which education is one, of developing that market.

Colonel CHANTLAND. Didn't Dr. Lubin present figures or data along that line, of bringing the lower level up?¹

The CHAIRMAN. Yes; he has done some of that.

Dr. NORTON. It is important, however, that easy conclusions and naive assumptions should not be encouraged by this undoubtedly important fact that education is in the picture. Mere increases in amount of education, irrespective of its quality, character, and incidences, are not likely to have important economic effects. Furthermore, education is only one of several factors responsible for the remarkable increase in economic productivity, which some nations have achieved during the last century. It would be superficial to disregard this fact. On the other hand, it is not necessary to make extravagant claims as to the economic value of education. The annual cost of schools and colleges, both public and private, in the United States is only about \$3,000,000,000 even in the most prosperous years. This, after all, is a minor fraction of the \$80,000,000,000 income which the Nation enjoys in prosperous years. The assumption that even a small part of such an unprecedented level of productivity can be credited to the effects of education would more than amortize its cost.

The relation of education and productivity, we would say, is most clearly understood when one looks upon them as complementary, interacting forces. The existence of a high level of productivity makes possible the financing of an extensive system of schools and colleges. Adequate provision for education is essential to a high level of productivity. Each makes the other possible, and progress is made by this route rather than assuming something of that nature. Modern economic productivity and popular education have developed con-

¹ See hearings, Part 1.

currently and both are requisite to the maintenance and improvement of the Nation's economic well-being.

It is of the utmost importance that we do not permit ephemeral conditions or fallacious opinions to blind us to the fundamental relation between education and economic well-being.

Representative WILLIAMS. Right in that connection, does that not conclude there must be a consuming capacity or the ability to consume before they are produced?

Dr. NORTON. I would rather not be too specific as to the order. I would rather rest on the statement, otherwise we will get into a whole new realm, which I recognize is important. I would rather say that goods and services must be produced before they can be distributed and consumed.

Representative WILLIAMS. But it is perfectly evident that our productive capacity is increasing and it is unbounded for that matter, through education and technological advancement, but on the other hand, unless there is some means devised by which there can be a consumption of that production—

Dr. NORTON (interposing). Right.

Representative WILLIAMS. I don't see how we can increase, or continue to increase, production. The fundamental, the very underlying principle, to my mind, is the question of how we are going to increase consumptive capacity and provide the means by which the goods, when produced, can be bought and consumed.

Dr. NORTON. I recognize the importance of dealing with problems affecting distribution and consumption, and I say that is very important, as you have just been emphasizing, but should not obscure the thing that I am principally concerned with this morning, the crucial significance of conserving and upbuilding the factors essential to a high level of production. The two are not out of relationship.

Representative WILLIAMS. Of course, I don't want to be understood as intending to counteract that tendency in what I say.

Dr. NORTON. I realize that.

Representative WILLIAMS. I am heartily in accord with what you have said with reference to education's part in this advancement.

The CHAIRMAN. Well, isn't it an important thing to consider, even now—the answer to the question propounded by Congressman Williams, which comes first and which in the interest of society should be made to come first, the capacity, the ability to consume, or the production? Now, let me say this, before asking you to give us your opinion, that before the modern advance of technology, when industry was practically confined to the home and to the farm, those who lived on the farm and those who lived in the home produced what they wanted.

In other words, they geared their production to their own well-recognized capacity to consume, and they could fit one to the other because they were themselves both the producers and the consumers. But technology has caused another factor to intervene. We have broken down production into such specialized trades that the capacity to produce has outrun the ability to consume, has it not?

Dr. NORTON. If you give the proper definition to ability, yes; I will agree.

The CHAIRMAN. What is the proper definition of ability?

Dr. NORTON. Well, if you mean the willingness and readiness to consume if they can get hold of it, right.

CONSUMPTION LAGS BEHIND PRODUCTION

The CHAIRMAN. That's right, exactly what I mean. The desire to consume may be there, but the purchasing power has been lacking because the productive capacity of individuals has been cut off. The individual who formerly could produce upon the farm because it was his farm was in a much better position so far as stability of his living standard was concerned than the person whose capacity to produce is dependent upon his getting a job from some large industrial organization, a job which he cannot command. He could command it under the old economic system. Do you agree with that?

Dr. NORTON. You have undoubtedly outlined an area of extreme importance, and in my emphasis on the production side I don't want to give the impression that I failed to recognize the importance of that area.

The CHAIRMAN. Still you haven't given us your opinion of which does come first.

Dr. NORTON. I wouldn't think that my opinion was of great value in that area.

Dr. ANDERSON. Mr. Chairman, I might say that the second expert of the day, who is an economist in this particular field, is going to devote most of his time to trying to answer that one question.

Dr. NORTON. And I am anxious to give him the right of way in a few minutes.

The CHAIRMAN. Congressman Williams said that if we find the answer to that question we will have done our job.

Dr. NORTON. I was tempted to make a facetious remark, and here I am speaking as a layman. I will just say that that argument is about as difficult as deciding whether the egg or the hen comes first.

It is sometimes stated that less education should be provided since as a Nation we are already producing more than we can consume. The fallacy of this conclusion is readily demonstrated by referring to studies such as those of the Brookings Institution, which clearly demonstrate that even at the peak of production in 1929, we were producing less than enough to provide an acceptable standard of living for all Americans. There is every logical reason to continue the policy of expanding our productive capacity in an orderly and efficient manner. All agencies which contribute to this goal should be effectively maintained.

Some will point out that even well-trained workers now find it difficult to obtain employment, particularly during the depression. Accordingly, they would propose that fewer workers be trained and that the percentage of unskilled workers should be allowed to increase. I believe this is a counsel of despair. Followed to its logical conclusion, it would lead to economic retrogression or an uneconomic population of low-skilled, low-producing workers. We cannot afford to base our long-term educational policies upon our present temporary economic maladjustments. This would be equivalent to assuming that such problems as serious unemployment, production far below potential capacity, and similar depression maladjustments are permanent and incapable of solution. Much of what we have a right to hope for would be impossible if such an attitude were to become the basis of public policy. A far more intelligent approach, we would believe, is to assume that human intelligence will find solutions to present

economic problems and that most, if not all, workers possessing training and diligence will eventually find real opportunities for service. Certainly such workers—and by “such workers” I refer to trained workers—cannot be absorbed if they do not exist, and they will not exist unless they are trained.

It is important to note, also, that even in the depression trained workers found it far less difficult to obtain work than did those without training. A disproportionate percentage of the unemployed is made up of unskilled labor. Furthermore, there appears to be an actual shortage at present in the supply of some types of skilled labor.

Available evidence, therefore, suggests that both individual and general economic welfare require that we should develop every practical means for increasing, rather than decreasing, the percentage of trained workers.

Mr. O'CONNELL. On what do you base the statement that a disproportionate percentage of the unemployed is made up of unskilled labor?

Dr. NORTON. On certain factual studies that have been made. I would particularly cite you Census of Partial Employment, Unemployment, and Occupation, which was issued for 1937 by the Government Printing Office. There have been a number of studies on a factual basis that quite clearly demonstrate this to be the fact.

Some will contend that there will be no one to do unskilled labor if too many workers are trained. This attitude, again, is based upon short-term considerations. The whole advance of western society economically has consisted in discovering efficient means of performing labor of the type which in earlier times was done by unskilled workers. As the number of trained workers increases, mechanical ways are found to perform routine work. The training of unskilled workers should continue, subject only to the limitations of their capacity and willingness to take the training involved. The economic efficiency of a society increases as its proportion of unskilled workers of low productivity decreases.

There is serious danger that shortsightedness will prevent the development of long-term policies in education, essential to economic well-being. It is unfortunate that forces growing out of the depression have caused us to decrease expenditures for education, while those for relief have been enormously increased. Humanitarian considerations may have made this necessary, but it is a trend which should be reversed at the first opportunity. In the field of physical well-being, prevention of illness and the building of abundant health is recognized as sounder practice than emphasizing the curative side. The analogy has applicability to economic well-being.

Our economic health should be protected at all costs. Continuous education for replacement of economic knowledge and skill is of supreme importance in a technological society. The length of the period of training and the brief span of a man's working years testify to this fact. Education has an enormous job to perform in merely maintaining the accumulated capital of knowledge and skill. Every death of a professionally or technically trained worker reduces this capital unless it is currently replaced.

Willford King, well-known economist, has this to say on this important factor:

Some of the most expensive and important forms of savings are not tangible but consist of such things as accumulated scientific knowledge and the training of the human mind. Savings of the last-mentioned variety are extremely perishable, since they are constantly being lost through the death of the persons possessing the education.

Mr. O'CONNELL. I take it there is a certain volume of that so-called savings which is lost through technological change, too, that as a man might have been a skilled worker in a particular line for a period of years and would have accumulated that knowledge it might overnight, almost, have become worthless to him.

Dr. NORTON. It doesn't take death, if the industry you are working in so changes that it makes your training obsolete. Unless you are re-trained you become an unskilled worker. It is very important, perhaps as important as the factor of death, when industry is changing so rapidly.

An appraisal of the current situation clearly demonstrates that we have not provided facilities appropriate to the maintenance and expansion of economic capital. I want to emphasize that there are two chapters dealing with this point and giving extensive factual information in this report on Education and Economic Well-Being. I refer to the chapters, Existing and Desirable Amount of Education for Economic Well-Being, and Extension of Facilities and Selection of Students. It is a fact which you can document easily, that fortuitous factors to a large extent now determine whether children and youths shall have generous or little educational opportunity in the United States. Now, we are coming back to the point that Senator King was emphasizing, that although we have kept the door of educational opportunity open in this country, it has not been completely open. It has been open enough so that a considerable number of people could squeeze through, but it is also closed enough so that a great many people who happen to be born in a poor family or in a poor area or in some other restricted situation do not have a chance to go through that door.

"MORTALITY" IN HIGH-SCHOOL EDUCATION

Dr. NORTON. There have been a number of studies that justify this figure I am giving now: 30 percent, as a conservative estimate, of the youths in high school drop out for economic reasons. I would cite the studies on pages 135-142 of the Educational Policies book that document that statement. Some studies put it as high as 50 percent. Lack of money to meet college expenses not only keeps thousands of capable youths from entering college but is also one of the chief reasons for their withdrawal.

Mr. PIKE. Would you also say that too much money has put a great many people into colleges that perhaps clutter up the educational system?

Dr. NORTON. I think I know what you refer to—that we sometimes make rather poor use of the time of youths who go on for advanced education, but I would add further that if we offered the programs and the opportunities that they should have, and developed what you might call an ideal and practical educational opportunity, say, from the end of high school on, you would probably in toto increase rather than decrease the number of youths going on beyond high schools.

Mr. PIKE. But you wouldn't have them in those specific institutions where perhaps some of them don't belong.

Dr. NORTON. I think many of them are misplaced at the present time, misplaced as to the kind of training they are getting and various other factors. A youth's chance to prepare for high calling, or for any calling except unskilled labor, now in these free United States often rests upon such factors as the taxable capacity of his local school district, whether his father is a professional man or a laborer, which means whether he will be encouraged to go on or not; whether he happens to be born in the North or the South, in the city or in the country, or in an urban or even a suburban community. Large numbers of youths are prevented from continuing their education through high school and into college because of lack of ability to meet expenditures required. Many of these youths have superior ability, and I am not making that statement on the basis of generalities, I am making it on the basis of scientific investigations which have measured these youths as to intelligence and industry, and record in high school, and the facts show that about as many capable youths fail to go on to college as actually do go on.

Many of these youths have superior ability. When competent youths are given financial aid permitting them to continue their education they make outstanding records, and once again that is based on the studies connected with the N. Y. A. program and scholarship programs, that if you make a reasonable selection of youths from the very poorest families, families with less than \$1,000 a year of total income, and send them on to college, they make outstanding records. There are a number of studies that have demonstrated that beyond question.

The distribution of educational opportunity in the Nation today is such that the potential economic effects of education are far from being fully realized. Tens of thousands of youths each year are foolishly being thrown into the overcrowded ranks of casual and unskilled labor who could have qualified for callings which demand more and pay more. They have both the capacity and the ambition to so qualify. But we at the present time permit fortuitous factors beyond their control to sentence them to 30 or 40 years of low-grade and low-paid service. I would say that that is a thoroughly undemocratic situation. The youths thus condemned by an uneconomic social policy will earn less than they could have earned, and the Nation's income will be less than it might have been. Wise public policy urges that this undemocratic and uneconomic situation be corrected as rapidly as possible through the right kind of effectively free education.

Schooling must be made free enough so that its costs do not constitute an effective barrier to education. By effectively free schooling we mean schooling provided under such circumstances that persons who should have that schooling are not debarred from it by financial reasons, and literally tens of thousands of American youths who should have additional schooling and training today are being debarred because of financial reasons.

Because effectively free schooling is necessary to obtain maximum income, the economically wise society will continue making additional amounts of education effectively free, so long as the income which accrues from added productivity exceeds the cost of these additional educational expenditures. This will be done because there will be more left to buy other goods and services after such education is paid for than there would be if such education were not provided.

The development of a program for maximizing the economic effects of education should be initiated at once. Some educational funds now expended for less vital purposes should be directed to this end. Funds from this source should be supplemented by additional appropriations as rapidly as conditions permit.

This policy is justified on the grounds that the proposed educational program in the long run will yield substantial economic returns. It will pay for itself, since it promises to increase national income more than enough to cover the expenditure required. Education may not be self-liquidating in the immediate and narrow sense of a toll road or a harbor where tolls and wharfage fees meet original investment and maintenance costs, but education of the right kind is self-liquidating in a far more fundamental sense than material improvements can be. In contributing to increased productivity, it helps to create the economic basis in national wealth and income upon which taxation for education and other governmental activities, as well as our whole standard of living, depends.

Now, Mr. Chairman, are there questions you would like to ask?

The CHAIRMAN. There are many questions that I have no doubt that many of us would like to ask. Some of them, of course, have already been propounded to you.

Mr. O'CONNELL. I would like to ask one at the moment. Do you happen to know whether organized labor has any view with regard to what I understand to be a proposal to continuously extend the development of vocational training?

Dr. NORTON. I know of some of the opinions of the type that Mr. Phil Murray has, and doubtless of the type that you will get from Mr. Green, that have been issued by different labor groups. I have read about those; yes.

Mr. O'CONNELL. Are they, in general, sympathetic with your approach, or are they, in general, somewhat opposed?

Dr. NORTON. I think you have to say it depends somewhat upon the man you are talking with. I think Mr. Philip Murray appeared before this group earlier. You know his viewpoint and I don't need to emphasize it. And if you will go to the schools of Pittsburgh, where he happens to be a member of the board of education, you will find that their policy is to develop increasing amounts and increasingly effective vocational education, and so on that basis you could say that at least part of labor does emphasize the importance of increasing the amount of training.

Of course, I suppose anyone who is intelligent would emphasize the importance of just not increasing training in one particular realm or two or three trades. It should be a broad diffusion of training; it should be based upon occupational information as to where the outlets are, and most training should be given in those areas where the supply of trained labor is least. All of those qualifications have to be made, but I have a feeling that intelligent labor as a whole recognizes the importance of effective vocational training for the rank and file of workers.

Mr. O'CONNELL. You spoke of the fact that lack of sufficient facilities of free education was a barrier to be removed. It occurs to me there are other barriers with which a person who might have received adequate training would be apt to be confronted when he attempted to put his training into action. I would assume that in a highly skilled trade you would have to belong to or join in some

areas at least a union, and in some of the unions there would also be financial barriers, in the sense of initiation fees and things of that sort. You are discussing only one barrier.

Dr. NORTON. I am emphasizing that one barrier because the lack of education constitutes that barrier. There are many other barriers. If you happen to go to the right college and make the right contacts, you perhaps get other opportunities, and luck enters into the situation as well as skill and training. My emphasis would be, let's take down one barrier that should not exist in a democratic society, and that is the opportunity to obtain the requisite education. Certainly if you don't have the educational training you can't qualify, no matter how close your contacts may be, and therefore I would say that with proper guidance and advice, give every youth the amount and kind of training that his capacity and diligence says he should have.

Mr. O'CONNELL. I don't think we would quarrel with that.

Dr. ANDERSON. The next witness's testimony, which is directly connected with this, is discussional. We could perhaps finish before the lunch hour, as we have a terrifically heavy schedule this afternoon.

INCREASED PRODUCTIVITY OF LABOR

The CHAIRMAN. That would be quite agreeable to me if it is to the other members of the committee. I just wanted to ask Dr. Norton another question.

In your statement you said—

The economic growth of the United States may be epitomized in the fact that a growing percentage of trained workers has used more and more effective methods of work.

Dr. NORTON. Yes.

The CHAIRMAN. By that I take it that you are referring to the training which enables the worker to make the most effective use of all of the discoveries of science and invention, power-driven machinery, and the like.

Dr. NORTON. Right.

The CHAIRMAN. It is the application of trained skill to technology.

Dr. NORTON. Right.

The CHAIRMAN. That conjunction of trained skill and technology upon raw materials brings about the increased productivity of which you speak, and which you regard as necessary. Is that correct?

Dr. NORTON. That is right.

I would like to bring into the picture, though, the fact that a minority of our employed workers in this country, a minority of gainfully employed workers, are now in what you would call strictly manufacturing or mechanized industries. There is a whole series of occupations, for example, the distributive trades, which we are just now beginning to recognize on the basis of training, in which persons, by looking at their trade or calling as something that can be trained for, may become more efficient.

The CHAIRMAN. Well, even in the service industries mechanization is present in a degree that I think is sometimes overlooked.

Dr. NORTON. That is right.

The CHAIRMAN. The ordinary gasoline service station is just a marvel of mechanization.

Dr. NORTON. Right.

The CHAIRMAN. And yet, though many machines are used, there is also a great deal of personal, individual manual labor involved in running those machines.

Dr. NORTON. Right.

The CHAIRMAN. Even the beauty shop and barber shop of modern days use a lot of new devices.

Dr. NORTON. Right.

The CHAIRMAN. And yesterday we had a good deal of testimony with respect to mechanization upon the farm, so that even the agricultural industry has become mechanized. We see it almost wherever we turn.

Dr. NORTON. It is a very important factor in our lives.

The CHAIRMAN. But you were developing the application of training to natural resources, and so forth, to increase productivity, and then at the outset of your statement you were referring to the fact that at the time our country was first organized and the Constitution adopted, the national income was only \$677,000,000, and that this combination of training, skill, and technology has increased our national income, so I just wanted to lead up to this question: Is it your conclusion that the most effective way to increase the national income is to increase production?

Dr. NORTON. I would say, undoubtedly that is one of the important factors in the situation, because I would think that by definition you can't increase income and the general standard of living without actually increasing production.

The CHAIRMAN. Would you think that the national income could be increased by decreasing production?

Dr. NORTON. I would not.

The CHAIRMAN. That was the answer I hoped you would give.

Dr. NORTON. That is easy.

Thank you very much.

(The witness, Dr. Norton, was excused.)

Dr. ANDERSON. Mr. Chairman, the next witness is Dr. Harold F. Clark, an economist as well as an educator, and his procedure in presenting his testimony is a series of topical headings which he is perfectly willing to discuss as questions.

The CHAIRMAN. I would like to swear the witness.

Do you solemnly swear the testimony you are about to give in this proceeding shall be the truth, the whole truth, and nothing but the truth, so help you God?

Dr. CLARK. I do.

(Mr. O'Connell took the chair.)

**TESTIMONY OF DR. HAROLD F. CLARK, PROFESSOR OF EDUCATION,
TEACHERS COLLEGE, COLUMBIA UNIVERSITY, NEW YORK, N. Y.**

Dr. ANDERSON. In connection with this subject, we are discussing such things as bottlenecks to skilled trades and things of that kind. I know the witness and his background, and should like to question him to show the type of expert we have.

Dr. Clark, you are an economist?

Dr. CLARK. I am.

Dr. ANDERSON. How long have you been working in the field of economics?

Dr. CLARK. For the past 15 years.

Dr. ANDERSON. You have done expert study in the field of occupations and their relationships to our economy?

Dr. CLARK. I have.

Dr. ANDERSON. Have you published?

Dr. CLARK. Yes.

Dr. ANDERSON. What have you published?

Dr. CLARK. We have here a little volume on Economic Theory and Correct Occupational Distribution, another on Life Earnings in Some of the More Important Occupations in the United States, and some 160 technical articles in various journals.

Dr. ANDERSON. I might say, gentlemen of the committee, inasmuch as this is a field which I know something about, that this little volume on Economic Theory and Correct Occupational Distribution was the most provocative writing in the whole field of occupational distribution that has ever appeared in economic literature in this country, and Dr. Clark, prior to it, had developed the educational implications of occupational distribution to a degree that no other scholar has done in this country. Since then he has examined this whole field of occupational earnings and the relationship of economic theory and planning to occupational distribution, the very topic we have been discussing.

Would you proceed, then, with your testimony, Dr. Clark?

Acting Chairman O'CONNELL. You are at present professor of education at Columbia?

Dr. CLARK. Yes.

Mr. Chairman and members of the committee, the topic I want to discuss is the allocation of the labor supply of the country and its effect upon the level of economic welfare. First, I want to call to the committee's attention the fact that the bottlenecks caused by shortages of skilled labor in particular industries constitute one of the greatest dangers to a country in time of war.

The holders of these bottleneck positions in times of crises are in a monopolistic position, and are almost certain to take full advantage of that fact. The danger, however, is not due to the exceptionally high wages that will have to be paid in those fields, but to the fact that production will be held up in many fields. This, in turn, may cause dislocation in a large part of the economy.

Mr. PIKE. Do you think of any at the moment, Dr. Clark—any examples you care to give?

Dr. CLARK. Yes; I think we could all put our fingers on one or two, particularly in the machine-tool industry.

(Senator O'Mahoney assumed the chair.)

Dr. CLARK (continuing). It, of course, would have been child's play to prevent that. The type of community organization that I am going to try to outline in a few moments should have effectively prevented that very happening. That is just plain stupidity.

There is only one proper solution of this difficulty. This solution consists in having a large number of highly trained people for all fields. Adequately trained workers would have great flexibility in adjusting to a wide range of occupations. These bottlenecks could all easily be avoided by a rationally organized training program.

Mr. PIKE. You mean, there, the sort of training that leaves a certain amount of elasticity in the person so that if this job is displaced tech-

nologically, or doesn't require a full force at the moment, he can go over to another job that requires rather high schooling and swing into it in a short time.

NEED FOR CATALOGING OF AVAILABLE JOBS

Dr. CLARK. I mean that, but I mean something more than that, too. I mean a training program designed to achieve what in the past we might have called overtraining. The man will have a breadth of training that will enable him to go here or there, plus the fact that each community will have such a carefully drawn up plan that you will be able to look forward and see where your shortages are likely to develop. At the present time we never know until it is right upon us. We can go back now and see that there were indications that this shortage was going to develop whenever your machine-tool industry reached a certain stage of expansion, which it could reasonably be expected to reach at a certain time. In other words, in 1932 you should not have dropped your training program. There is no earthly reason for letting a man stay on relief, idle, when he will be very much better off being trained. We could have used the past 10 years, the greatest period in human history, to get an overtrained labor force without any expense. We didn't use it because the individual communities didn't have the plans drawn up in terms of their being likely to need people when the expansion came. It wouldn't have cost us a red cent.

The CHAIRMAN. How could that have been done?

Dr. CLARK. I would like to postpone the answer just a little, if there is no objection. If I do not get to it, I trust you will remind me.

The CHAIRMAN. Very well.

Dr. CLARK. The level of economic welfare of a country probably depends more on the quantity and the quality of the training of all of its workers than on any other one item.

There are those who would like to tell us that the level of economic welfare of a country is determined almost exclusively by basic resources, or a lack of them. A very casual comparison of such countries as Switzerland and Colombia, South America, would readily disclose that Colombia has far more resources. The difference between the two countries lies in the quality of their trained labor force. I have spent a considerable amount of time in the last 15 years studying and working in 58 different countries in the world trying to find out what does determine the relative levels of economic welfare, and you find essentially no relation between the basic physical resources and the level of welfare in that country.

Denmark, with almost no basic natural resources, has had an exceedingly high standard of living. Mexico, with large resources, has had a relatively low standard. Denmark has perhaps the most highly trained and skilled farming population in the world. Mexico's population is essentially untrained. Training of the workers, then, seems to be the key to determining the level of welfare of any country or even of the major sections of the country.

This highly trained labor force would also be a powerful factor in suggesting and bringing forth a continuous flow of new industries that would make possible a higher standard of living than this country now has.

In other words, your highly trained worker is able to see the next step; he is able to see the new industry that ought to be established; he has training, and certainly should be able to work out the technique of getting the capital and closing the gap.

A substantial amount of unemployment is caused by the lack of flexibility in the total labor supply.

There are many well authenticated case studies of heavy unemployment in a city and still a substantial number of jobs going unfilled. The classic one is the one in Philadelphia, made a few years ago, at a time of heavy unemployment. It was an actual factory-to-factory survey on one minor job, asking the manager how many people he would employ if a trained man for this job appeared, and it showed that quite a large number would be employed.

One of the classical cases existed in the Panama Canal Zone up until a few years ago. The case study can be found in a volume by F. W. Hosler, entitled, *The Administrative Organization for an Apprenticeship Program in the Panama Canal Zone*. This study showed clearly that many of the key positions in the Canal Zone could not be filled by adequately trained persons when they fell vacant. There was no systematic training program for them. This applied to many of the higher positions as well as to large numbers of positions requiring lower skill. There were actually substantial numbers of positions unfilled because no qualified persons could be found to fill them. At the same time there were large numbers of individuals unemployed but unprepared to do any specific thing.

The unfortunate fact is that modern technical industrial society does not have any mechanism to anticipate where jobs are likely to be and to provide adequate training for them. Each individual is left to flounder in his own ignorance and to collect what little information he can casually pick up. Some more systematic arrangements must be made to all communities to see that a complete and up-to-date record is kept of the probable need for new workers.

I want to outline in just about half a minute, if I may, and start on the answer to the chairman's question.

Dr. ANDERSON. I want to ask this question. You have stated that there are situations in which jobs are available of a skilled character. Are they usually of a skilled character?

Dr. CLARK. Almost always.

Dr. ANDERSON. And workers are not available to fill them. Do you care to generalize as to the extent of that in the total economy, or where it is located, how it manifests itself?

Dr. CLARK. I should like very much to generalize to this extent, that we do not know with any degree of accuracy, and the reason we do not is that we haven't the machinery that could possibly give us the answer. That is the basic point that I want to discuss for a moment, if I may.

I see no chance of making any real progress on this point until we get a change, in addition to what you might call your community organization. We need what you might call an occupational planning group in every community in the United States, representing every type of occupation, carefully organized, systematically meeting, studying the occupational need, being in contact with all the technical groups, looking as far forward as possible, making the plans for that particular community.

If in this community, after the most careful study, you find out that you are going to have 10,000 boys and girls leaving school—and we will just take the school-leaving group as an illustration—and you look over all of the occupations in the community and you find that only 9,000 can be absorbed, at that point you have, for the first time, set up the machinery to frankly face the issue of unemployment. Until you have that much information, you can't even discuss unemployment intelligently. In other words, you can't even get the answer to your question, you haven't the facts on which you can start. You have to go back and set up some kind of machinery of that order in every community in the United States.

If you find that 9,000 can be absorbed in present jobs, then the question is, what are you going to do with the other 1,000? Then you can begin to discuss it on a variety of bases. You can ask intelligently, "Do you want to reduce hours, and if so, how much would they have to be reduced in the reallocation of the labor force?" "Do you want to establish new industries? If so, what would they have to be?"

For the first time, then, you can frankly face the question of how many new industries you would have to establish, at what rate, of what kind, where would they have to be? Otherwise your talk must be in very vague generalities.

Mr. MAGINNIS. Professor Clark, do I understand that your idea would be to set up such a body, whether a commission or otherwise, with a certain number of members, say three members? Do you mean each large community, at the expense of that community or the Federal Government, would make it a permanent proposition?

Dr. CLARK. I would very much rather it would be a voluntary representative body from all the occupations, elected members from every occupation, meeting as an occupational planning body with no power, of course, in compulsion, but to really get the information continuous. It might meet once a month. In the larger communities, of course, it would have a small, paid technical staff.

Mr. MAGINNIS. Don't you think the practical difficulties about such voluntary propositions are that they only last just a short time and that sometimes the period is very short because every man is too busy to devote the time necessary?

Dr. CLARK. I don't think so. I think we have some experience in our city planning councils. I would not be dogmatic on that point, but I think we have enough experience from the planning of the physical resources to lead us to think we could get the ablest people from all the occupations. After all, it is one of the 2 or 3 most important aspects of the total community. I wouldn't want to argue the point. If we find out we ultimately have to pay for it, all right. I would be very insistent, though, in my own opinion at least, that they root in the community, that they grow out of the community. I would want as little overhead compulsion coming down from Washington and the State capital as I could possibly get. I would try to get it springing up out of all the occupations, all the communities, with a minimum of coordination.

Mr. O'CONNELL. The problem is rather a national problem than a community problem.

Dr. CLARK. You have to have a coordination, plus or minus, in your communities.

Mr. O'CONNELL. You might have 1,000 extra workers in one community that might not be solved by that community.

Dr. CLARK. It is a fairly simple coordinating job in a State, I think, if those local bodies are really functioning actively.

Dr. ANDERSON. There will be difficulties arising in connection with the mobility of labor.

I am thinking now not only of occupational but also of geographical mobility.

MOBILITY OF LABOR

Dr. CLARK. Quite; that is a complication which you would take into account in setting up your plans for your individual community. It is no objection to the plan; only another complication in carrying it out accurately. In the early stages it would introduce another inaccuracy in your estimate, but it makes it all the more important, if you are trying to set up a training program in your local community, that you have made the best guess you can of how many of those people are likely to be absorbed in the particular community on the basis of past experience, on the basis of the intention of all the people, and everything else.

The CHAIRMAN. How could a local community do that with respect to a national industry? Let us take, for example, the telephone industry, because it covers the entire country. Yet, because it is a national institution, governed by a board of directors operating from, ordinarily, some one central head, how could a community in the far West make any effective plan with respect to training the youth of that community for employment in the telephone company?

Dr. CLARK. You gave me an awfully easy one, Mr. Chairman.

The CHAIRMAN. Good.

Dr. CLARK. I have worked a little with Mr. Bridgeman and some of the other technical men of the staff there, and it would be simplicity itself for them to make the estimates—

The CHAIRMAN (interposing). For whom to make the estimates?

Dr. CLARK. For the people in the telephone company to make the estimates of what they thought they were going to do. Then they pass that back down to a little town of 10,000 in central Nebraska. They employ 9 people. They estimate a certain rate of expansion. They estimate that they will take another employee in 2 years. That information could be obtained right today in any community that wants to take the trouble to get it. There isn't any excuse at all for its not being done, probably for 25 to 40 of the major large organizations.

The CHAIRMAN. The telephone industry is one, as was pointed out during the testimony of Mr. Harrison, the vice president here at these particular hearings, which depends for its success upon the number of contacts it makes with individuals. It is a direct producer to consumer industry, so to speak.

Now, another industry is the railroad industry, the transportation industry, and there are many communities on various systems which are service connections to the railroad and which do not at all depend upon the amount of business that those particular communities produce. They may have a large or small demand for labor, dependent not upon anything that happens in that particular community but

upon what happens on the whole in the whole field of the railroad itself.

Dr. CLARK. Right.

The **CHAIRMAN.** And the decision as to what shall be done in this particular community, in the shops for example, is made not upon the basis of anything that exists in that community but upon the judgment of the board of trustees or the operating vice president in a distant community upon consideration of the over-all picture of the transportation industry.

Dr. CLARK. And all I am saying is that we should have arrangements by which the best guess he can make moves down to this planning body in the local community.

I happen to have graduated from high school in a little railroad town. What did the individual do there? He had to guess at all of that and make his guess as to whether there was going to be a job for him in the railroad shop when he finished high school.

Now, as you know, all you have said is that it isn't a perfect guess that the vice president of the railroad is going to make in the light of all the factors. It is going to be a lot better than this boy's in the local high school. All I am saying is, let's get all the information we can. It will not be any better than our technical knowledge, but it will be incomparably better than this poor little individual's trying to guess, "Is there going to be a job there? Are they going to move these shops? Is this particular process going to fade out of the picture?" with no contact between the school system, the people giving the guidance, and the people making the decision.

The **CHAIRMAN.** There are innumerable communities in the United States which, by reason of the development of the national industry, are pay-roll communities dependent upon the contributions in wages made by national industry which happens to pass through that town. You may have a railroad running through it, you may have an airplane line running through it; you may have, and probably do have, a number of chain stores in almost every one of these communities. And you have the oil industry, with filling stations that are owned and operated or sometimes just leased by a large oil company, the whole policy of which is directed from some other and distant community, industries over which the local community as a community, as a city or a town, the county as a county, and even the State as a sovereign unit in the United States has no jurisdiction, or no effective jurisdiction, at least, whatever.

Such communities are dependent almost upon the largess of those who are managing these great national industries. In my State, and in most of the Western States, for example, the farmer and the rancher, the rancher who raises livestock and wool for the market, must ship their product to the packing centers, and they are dependent upon what the managers of the packing industry are content to pay. Perhaps I shouldn't say "are content to pay"; what they do pay, but the determination of the price is made not upon a basis upon which he is willing to sell or desirous of selling, but upon the basis on which the purchaser is willing or desirous to pay.

And so, in an ever-increasing degree you have this divergence between the economic independence of the local community and the local citizens of the community, and the control exercised by a national industry.

Now, will training help to bring the sort of solution that you were talking about?

Dr. CLARK. The very least we can ask of those organizations is that they send the plans back. At least I think it is a perfectly reasonable request. We have tried it a little with them and we have every reason to think that with all of the other faults that those organizations may or may not have, they will be willing to pass down the best estimates that they can make of what is likely to happen. The specific issue here is whether it would complicate the local community estimates of the training and employment situation, and I am quite inclined to think that we can handle it all right.

Mr. O'CONNELL. Let's see how your plan would work in connection with New Castle, Pa., which is a case which was described to us before this committee last week, where, in a town of 50,000 people, some 1,600 people were let out. Under your plan what would have happened?

Dr. CLARK. Most of the tragedy of New Castle would have been prevented.

Mr. O'CONNELL. It would have been?

Dr. CLARK. It is going to be a beautiful case study when somebody goes back in the record and pins the blame: "There was the day that could have been predicted," in 1900, 1905, 1910, I don't know how far back. But long ago somebody should have known that there was likely to be a change. At that date a storm signal should have gone up over the high school and every school in that community saying, "There is danger ahead here, and here are the facts. Here are the reasons why we think there is going to be a calamity in this community. In the light of that, do you want to make your plans to move out, to make your contacts?"

No; we wouldn't do that; we pile them up, pile them up, the same thing that I have seen in coal community after coal community in Pennsylvania when everybody on earth knew that the coal mine was going to shut down for 3 years or 5 years, except the people running the local school. They wouldn't take the trouble to find out, they wouldn't give the warning. All I am saying is, let us do the best we can. Now in some cases it is very well done. At least it will give the boys and girls a little better chance.

The CHAIRMAN. Of course, you realize how difficult and distasteful it would be for the principal of a high school in that dying community to say, "Now look out, boys, this town is near the end of its rope."

Dr. CLARK. I know those little mid-western towns well enough, having spent most of my life in them, to know that he couldn't hold his job and do that, but he could present certain factual evidence and say, "This decision has been made," and this or this or this. All I am saying is that he certainly hasn't really helped those boys and girls to let New Castle reach the stage that he has. That is all I would say: get the best information you can, the best in the community on the total situation.

PRODUCTIVITY OF TRAINED LABOR

Dr. CLARK. I think I had better move on to my next item. A trained labor force produces more than an untrained one. I am going to omit (a) if I may, entirely. Dr. Norton referred to it. Essentially it is the argument that if you get it down to a specific case the trained farmer will produce more than the untrained one.

(b) Presumably, farmers are trying to make these adjustments all the time, and the same is true of all individuals. But lack of training constitutes perhaps the major barrier that keeps people from making these shifts and moving from places of lower productivity to higher productivity. In my little book, *Economic Theory and Correct Occupational Distribution*, this discussion is followed through at length, and I think it is amply demonstrated that there are all kinds of barriers in our society due to lack of training which prevent many persons from moving from occupations of low productivity to those of high productivity. It is a perfectly safe guess that in any country in the world a very great extension of the training of the working force will enable such shifts to take place and make it possible for workers to move from where they would be producing little to where they would be producing much.

I want to start at this point to answer the question raised in the early discussion of Dr. Norton about the consumption of this increased production. I obviously do not claim that I have anything like the final answer; it is just a little light on the issue.

Some individuals are bothered with this point because they say, "We cannot buy or consume or use all we can now produce, so why train more people to produce more?" It is too well established for argument that one of the reasons we cannot buy more is that there are all kinds of monopolistic tendencies that hold up prices, and among these monopolistic tendencies are relative shortages of trained workers in particular fields. This great expansion of trained labor would reduce the cost of many products and would thereby enormously expand purchasing power. There seems to be no possible answer to the contention that, all other things being just as they will be, a highly trained group of workers will produce, distribute, and consume more than a poorly trained one.

The next point I think goes into the discussion more fully. Presumably, much of the reason that we have difficulty over this consumption issue, to put it mildly, is lack of purchasing power. The American way of bringing about a fairer distribution of the income and production of the country is to provide more nearly equal opportunity. Certainly as far as earned income is concerned—and this constitutes perhaps 80 or 85 percent of the effective spendable income—any presumed unfairness in its distribution is caused almost entirely by lack of opportunity. This lack of opportunity hinges quite largely upon lack of training. You see, we are beginning to chisel away at this lack of purchasing power. First, we are going to actually produce things more cheaply, people will have effective purchasing power in greater quantity; second, as far as the earned income is concerned (and keep in mind that is something between 80 and 85 percent of it), you can bring about almost any distribution of that if you are willing to set up a training program to train where you have the high incomes and to pull the people out of the low incomes; that is your easy, obvious, American answer to your lack of purchasing power.

The CHAIRMAN. You don't mean to say that training of itself will do that.

Dr. CLARK. Training will do practically all the job, Mr. Chairman.

Dr. ANDERSON. In other words, Mr. Clark, the returns in any unusually highly paid or compensated occupation are returns for a scarcity position.

Dr. CLARK. A monopolistic tendency, right.

Dr. ANDERSON. And if you multiply the number of competent people offering that service you thereby divide the amount available for that expenditure among them, reducing the amount anyone receives, making the price lower to any consumer of that service.

Dr. CLARK. And at the same time you are pulling the people away from the bottom, creating less pressure on the income down there, so that their income goes up automatically. The important thing is, of course, the total production of goods and services.

The CHAIRMAN. But training of itself would not create the jobs, would it?

Dr. CLARK. The training will do most of it, Mr. Chairman.

The CHAIRMAN. That is a very simple answer.

Dr. ANDERSON. One point bothers me greatly in examining that theory. You are presuming that occupations are at work in a competitive field. Now, how competitive are these unusually scarce occupations, for example, the skill of a highly trained surgeon or the managerial skill which brings Mr. Watson around \$400,000 a year? Even though you put 10 Mr. Watsons in the field, would you thereby create 10 Watson jobs and split the \$400,000 among them?

Dr. CLARK. We have a great deal of evidence on the question. Now, I am quite willing to admit that you may have certain positions that seem to be so highly protected monopolistically that you cannot get into them, and some of the very top movie salaries may be in that class. Personally, I doubt it. If we may take the case of the railroads, there was a time when the railroad salaries, as you know, in the eighties and nineties of the last century, were relatively very high as compared to almost all others. I am not saying that is the only reason that railroad salaries have gone down, but as you have trained more people capable of doing this thing—we haven't done it deliberately and consciously, it has just been a little accidental—there has already been pressure down; there are other reasons, of course, but there are two basic answers to the question. The first is that it wouldn't make very much difference in the total purchasing power if you ruled out a few hundred or a few thousand of these very large incomes. Certainly, after you get out of those, competition will work. The fact that you have a limited number of people here trained for these jobs enables these people to get relatively high semimonopolistic incomes—

Mr. PIKE (interposing). You are thinking, say, of the building trades having priced the housing possibilities almost out of the market, and that sort of thing?

Dr. CLARK. I would want that investigated awfully carefully to see if there were monopolistic elements in it. At least the issue ought to be investigated. All I would say here is that a rational society will see to it that as many as possible of those monopolistic protections to positions are removed, and that will, if you train enough people, tend to adjust income to a fairly equal level, which will bring the purchasing power and will consume your goods.

The CHAIRMAN. Now suppose that we were to establish a school in Washington, D. C., to train telephone operators on the manual switchboard. What good would that do?

Dr. CLARK. Oh, absolutely none. Obviously, all of your planning for occupations must be in terms of the way your technology is moving.

The CHAIRMAN. In other words, your training must be keyed to the opportunity for jobs.

Dr. CLARK. It has to be, always. But you—

The CHAIRMAN (interposing). All right, then, which comes first, the training or the opportunity for jobs?

Dr. CLARK. No question about that, the training comes first. The evidence is clear the world around.

The CHAIRMAN. I wish you would develop that.

Dr. CLARK. Well, you can look at it comparatively in the various countries of the world. The countries that have the trained labor force are those that have, the world around, moved up. For instance Denmark was just a sand stretch sticking out in the North Sea.

The CHAIRMAN. Now, of course, I haven't studied this question as you have, but the impression that I get from a rather inadequate view of economic development is that training inevitably is a result of the desire of some man to do a certain thing. Necessity is the mother of invention. Men became trained to build bridges across rivers because first of all they wanted to cross the river on a bridge. They didn't undertake to train bridge builders before they conceived the necessity and the desire to cross a bridge.

Likewise, no railroad workers, to jump through many centuries, were trained until after the opportunity for the job had been developed, and the first training in railroad employment as in every other line of human endeavor came from the practical application of an untrained person's mind and body to the doing of a job which his mind had conceived. If that be true at the beginning doesn't it necessarily follow that it must be true all the way through our development? Now the training, for example, of a man to operate a continuous strip mill depends upon the conception of the strip mill first.

Dr. CLARK. But you see, the—

The CHAIRMAN (interposing). In other words, the creation of the job first.

Dr. CLARK. No.

The CHAIRMAN. Give us the other side.

Dr. CLARK. You have a job situation existing in the United States at the present time.

The CHAIRMAN (interposing). We have a job situation in the United States nonexistent at the present time.

TRAINING TO REDUCE UNEMPLOYMENT

Dr. CLARK. Quite right, to the extent of 8,000,000 or 10,000,000 workers—nobody knows quite what. Any movement toward sending more people, training them for, moving them toward the high-paid jobs, will create more jobs, it will create more purchasing power, it will move toward the solution of your consuming problem, which was bothering the committee an hour ago. The mere fact that it will move toward that will bring about a better distribution of your income. Probably most economists would admit that if you have a more nearly equal distribution of income, the income would tend to be spent more smoothly, and I think again most economists would agree that if your total income were spent fairly smoothly we might move fairly quickly toward the picking up of this unemployment.

The CHAIRMAN. I wish you would come down to my office after this session is over and go through the list of applicants who have written in to me, trained applicants, who would like jobs somewhere or another. They can't get them in industry, they can't get them in government; they are trained, they are capable, they are educated, they have good characters, they have all the qualifications that go to make up a competent worker or a competent educator, but they just don't have the job.

Dr. CLARK. Now, we find that objection raised chronically by people saying, "Well, why train any more doctors? I know four doctors who are on W. P. A." So it doesn't make any sense to say train any more. But we have to watch that. You have to watch that argument awfully carefully. If you put it to the extreme the other way and say, "Well, why not train more doctors?"—if you do, then doctors' incomes will tend to go up more, you will tend to accentuate the inequality of income, you will cause all kinds of other incidental things to happen in your economy, and you will actually cause more unemployment by the process. If you tend to train more doctors, the tendency will be for doctors' incomes to go down.

The CHAIRMAN. The tendency will be to develop socialized medicine.

Dr. CLARK. I am inclined to think it is far more likely to happen if you keep to the present rigid determination of the number of doctors. Essentially all we are arguing for is to try to find out the total number of people that ought to be trained for the present occupations. Then you would be in position to say how many new occupations you would have to train to be in a position to move right up to that issue.

The CHAIRMAN. In other words, instead of having through W. P. A. during the last 5 years created jobs, made work in many instances, for trained and untrained persons, you would have given them more training. Is that the idea?

Dr. CLARK. We have a double answer to that.

The CHAIRMAN. Before you answer it, let me just call your attention to this. The W. P. A. comes annually before the Appropriations Committee of Congress to ask for funds that may be necessary, and in the showing the Administrator always lays before the committee the schedule of wages. It is divided into unskilled, semiskilled, and skilled at least. In other words the W. P. A. administrative force divides the labor supply into various classes of skills. Now, these skills run all the way from the manual laborer to the highest kind of professional or cultural skill.

Dr. CLARK. But there is exceedingly little at the top. We have this very large study of about 5,000,000 people on W. P. A., so we happen to have the facts there, and it is overwhelmingly weighted toward the bottom. Now, you are quite right in saying we do have substantial gross numbers at the top, but that still doesn't change the—

The CHAIRMAN (interposing). We had a witness here speaking for the white-collar office worker. His complaint is that this highly-trained, well-educated office worker, sometimes of a professional character, a college graduate, trained in economics, and the like, has been unable to secure employment. I ask would it be beneficial to him and to society to give him more training or train him in a different field?

Dr. CLARK. You can't even say whether you need any more economists, perhaps you have too many already.

The CHAIRMAN. Now, we come down to need, don't we?

Dr. CLARK. There isn't any way to answer that question with our present machinery, absolutely no way at all. I would like to go back and answer part of one of your earlier questions. If you had had the proper kind of organization in your community, saying that your unemployment was here and here and here, and that you could only use this many people in your present occupations, it is conceivable, at least, that if half of the money that has gone into W. P. A. had gone into the careful development of those new industries and occupations in industry we would not have a shortage of workers in the United States at the present time.

Mr. O'CONNELL. In your reference here to earned income, you don't mean that earned income is 85 percent of all income, do you?

Dr. CLARK. No.

Mr. O'CONNELL. Earned income generally is more spendable than income from dividends—

Dr. CLARK (interposing). No; it isn't that. All I was taking out is the money that under any economy has to go back into improving the capital plant, and you can't spend it, it isn't spendable for ordinary consumer goods.

Mr. O'CONNELL. What do you mean by "earned income?"

Dr. CLARK. All wages and salaries.

Mr. O'CONNELL. Regardless of how high?

Dr. CLARK. Regardless of how high, and I would throw in all farm income, all salaries of all kinds. It would compare with the usual figure of 60 or 65 percent—the one you usually get.

Mr. O'CONNELL. Would you say that \$400,000 that would be received by Mr. Watson would be as spendable as a practical matter as the equivalent amount if divided among 400?

Dr. CLARK. No; it wouldn't, and I don't think we have made it clear yet as to why real competition in the long run will put some pressure on those high-paid jobs, and will get more people in them. Now, it won't do it quickly, it won't do it suddenly, and that is the reason it is awfully hard—

The CHAIRMAN (interposing). Competition of what kind? Competition to cut down the compensation?

Dr. CLARK. No; competition of capable people who could do the work and over the long periods—

The CHAIRMAN (interposing). Won't that result in the reduction of compensation?

Dr. CLARK. Definitely, yes; it will.

The CHAIRMAN. So that you train more people in order to lower the price which the trained worker receives; in other words, to lower the wage.

Dr. CLARK. Right.

The CHAIRMAN. That is correct?

Dr. CLARK. Certainly; but you are doing another thing; you are raising the total. You see, his is coming down, and the bottom is coming up. That is the reason you are chiseling at the consumer problem.

Mr. PIKE. Referring to the scarcity of wages, whether they be wages, salaries, or profit percentages.

Mr. O'CONNELL. In fact, a higher percentage of income going into consumer's goods. Taking Mr. Watson's case as an example if his \$400,000 salary were paid to a hundred persons at \$4,000 each, I take it, a much more substantial percentage of the total would go into consumer's goods.

The CHAIRMAN. That might result in the reduction of the hourly rate and the weekly wage of carpenters, and on the other side of the scale in the annual salary of faculty members.

Dr. CLARK. Quite likely. The annual income would be almost certain to drop.

The CHAIRMAN. The annual income of the worker himself, the individual worker.

Dr. CLARK. The hourly wage of the individual building worker, the carpenter, to whom you referred a while ago, would almost certainly do that.

The CHAIRMAN. But he would work a longer period during the year at a lesser rate; he would have more work and less leisure for the same pay.

Dr. CLARK. Probably. He should have that choice though.

The CHAIRMAN. And the professor would get along without his sabbatical year, I suppose.

Dr. CLARK. I shouldn't be at all surprised.

Dr. ANDERSON. But isn't it true that we have developed a whole series of institutionalized forms and protections, so that there is an extreme rigidity against any such inroads as you suggest? You would have to do more than simply multiply the number of workers for a given level of employment. You would have to do this occupational training and placement program that you indicated earlier in your community approach, and beyond that you would have also to examine into the reasonable ways of breaking down the institutions protecting this rigidity.

Dr. CLARK. Yes; and that, of course, is a long term affair and some people get awfully pessimistic and say "Why discuss it?" The only thing is the longer we put it off the worse it is going to be. We have to make a start on it.

Dr. ANDERSON. I would suggest a break in lunch hour and come back for this.

The CHAIRMAN. Your paper has elicited more questions than we had expected. The committee will stand in recess until 2:30.

(Whereupon, at 1:05 p. m., a recess was taken until 2:30 p. m. of the same day.)

AFTERNOON SESSION

The committee resumed at 2:30 o'clock, on the expiration of the recess.

Acting Chairman KING. The committee will please be in order.

Dr. ANDERSON. Mr. Chairman and members of the committee, just before lunch, we were interrogating Mr. Harold Clark, who is ready to continue and close his presentation.

Dr. CLARK. I want to emphasize one point again, that perhaps was not made clearly. There is an obligation so to organize our communities that we will use all the people to do all the work. It is that positive approach to the problem that I think we are all interested in.

There is one other thing I should like to say, emphasizing the

difference between a short-term and a long-term approach to the problem. The question was raised this morning whether just a training program alone, just training more people, would automatically solve this problem of unemployment. Well, obviously it would be unreasonable to expect that to happen.

We did not make it clear this morning that there is a fundamental difference between the short-term effect of training more people, and its effect in smoothing out incomes, increasing purchasing power, getting a better flow of many things in the economy.

It is partly for that reason that I would like to emphasize the difference, that in your long-term program, if you start to plan properly for the use of your human resources, many things happen that should very greatly ease these drops.

Mr. PIKE. You are thinking in terms of a generation now, aren't you?

Dr. CLARK. Fully, yes, and it would be a very great mistake to assume that I was advocating this morning that we could go out and train these 11,000,000 people and unemployment would disappear.

The other point is the important one, that gradually, if you raise your level of training over a long period, it has the indirect effect toward equalizing income, and that would go far to answer the question raised by the chairman as to how it will have a good effect upon the question of purchasing power.

INCREASE COMPETITION FOR HIGHLY PAID POSITIONS

Dr. CLARK. If any of your earned incomes are unduly high as compared with others, the most effective way to deal with this situation is to increase the competition for those positions. Essentially, this means equipping more people with adequate training to enter the competition.

In my volume, *Life Earnings in Selected Occupations in the United States*, a report of the income to be expected for various lines of work in this country is made. There can be little doubt that much of the differences in these occupational groups is caused by lack of adequate training to enter the more highly paid ones. The United States would be far better off if it paid less attention to some other efforts to redistribute income and paid more attention to the historic American claim of providing equality of opportunity and adequate training. We have not been doing this. Consequently many of these inequalities have become much larger than they would have become if we had lived up to our claim of equality of opportunity for training.

Acting Chairman KING. Of course, you appreciate the fact that there is a very heavy responsibility in order to achieve the end to which you refer, resting upon the parents and upon local communities?

Dr. CLARK. Yes; and they should be encouraged in every way we know, to strain themselves to the limit to do it.

Acting Chairman KING. Your thesis does not contemplate the Federal Government taking over the training and education and public schools?

Dr. CLARK. I would be strongly opposed to it, and I emphasized at great length the extreme importance of building up these local planning bodies to deal with it. I would have just as little Federal control as possible in it, and just as little State interference and control. I

would throw everything back on the community and back on the individual that I could possibly get there.

Acting Chairman KING. There may be considerable technical development under the totalitarian state, but there is a deprivation of those fine qualities which are essential to the development of the highest form of citizenship, including moral and spiritual qualities.

Dr. CLARK. I have said on various occasions that a dictator can solve unemployment very easily by just saying, "You have to go out and dig this ditch," but it isn't worth that price. In other words, we have to work it out on a democratic basis, working up from the bottom, showing the people of each community how they could organize together at that job.

Acting Chairman KING. Don't you think there has been too much emphasis in some of our schools upon the proposition that they must aspire to the highest political job, and the expression is frequently heard, "Hitch your chariot to a star," as a result of which many of the young people, instead of qualifying themselves for positions in what some call the "humbler" but after all, they are the basic things of the community, and get off on an intangible theory?

Dr. CLARK. I agree entirely with that.

Acting Chairman KING. Proceed.

Dr. CLARK. All things considered, the most effective and fairest way to bring about a reasonable distribution of the income of the country is to move as nearly as we can toward equality of opportunity, to begin with—and perhaps the crucial element in this is completely free and open training for all of our citizens.

The sixth and last point, one very much neglected and extremely important part of the training to all individuals is to train people to do things for themselves.

This does not mean going back to a nonspecialized or handicraft economy. But particularly for the third of the Nation that is reported to be ill-fed, ill-housed, and ill-clothed, it is extremely important that we explore every possible way to train them to provide as many things as possible for themselves.

For instance, evidence is quite clear that in many communities the diet is very inadequate. Evidence is equally clear that in many of these communities even the poorer members of the community, by making certain changes in their old habits, attitudes, and actions, could very greatly improve their diet. There are many rural and semirural communities which have very bad diets. We have made a very careful check in some of these communities and have found that by adequate training those people could produce all the things necessary for an adequate diet.

A good many people objected at first. They said, "Well, you will stop the purchasing of goods if they produce these things for themselves." But that misses the point. Because they only have a limited amount of money, they are going to spend the money anyway, and if they can produce more things for themselves, that is, particularly the bottom part of the economy, the total economy will be that much better off. Our relief load will be less and their standard of living will be that much higher.

The Sloan Foundation is carrying on certain experiments that may turn out to be of historic importance to this country, in trying to discover what persons of these very low-income communities can do to

increase the adequacy of their food supply, their housing, and their clothing. If the longer studies now projected bear out the same conclusion or the preliminary experimentation, we may find the most powerful evidence in support of training people and thereby improving their own level of economic welfare.

There has been a rather sensational development in certain low-income communities, in the Southeast and Middle West, where some profound changes are occurring in the economic conditions of these people by simply helping them to grow things for themselves or helping them to do certain things about their own housing; many of the things that you were suggesting this morning—working with their hands, doing a long list of very important things.

(Senator O'Mahoney resumed the Chair.)

Dr. CLARK. From any standpoint, then, it is of crucial importance to a country to have the proper allocation of an adequately trained labor force. An inadequately trained labor force may very well be a disastrous factor in time of military crisis. Economic welfare of countries in general depends probably more upon quantity and quality of the trained-labor force than any other single factor. An adequate and expanding capital equipment and highly trained labor force will almost guarantee the economic welfare of any country.

Substantial unemployment is caused by the lack of flexibility of a labor force inasmuch many times there is heavy unemployment and at the same time there are jobs unfilled because there is no one trained to fill them.

All the detailed studies that have been made indicate that a trained labor force actually turns out more goods and services than an untrained one. The American way to produce a fairer distribution of the income of a country is to offer the necessary background and training so that each individual can compete for the top positions. This would probably bring about a distribution of earned income that would come close to satisfying most individuals of this country.

And, lastly, it is extremely important to train particularly the very low-income groups to do as many things as they can to increase their own level of economic welfare. Seemingly the results will be sensational if they do.

The CHAIRMAN. Professor Clark, we are very much indebted to you. Are there any questions to be addressed to the witness?

We were very happy to have had you with us, Professor, and thank you very much for the statement.

Dr. ANDERSON. Mr. Chairman, the next witness for the afternoon is William Green, president of the American Federation of Labor. You will remember that he was invited to appear early in our proceedings and due to unforeseen difficulties in his schedule was unable to do so.

We are very happy to have him here this afternoon to make a statement that represents the viewpoint, I presume, of Mr. Green and of the American Federation of Labor on the subject of Technology and Unemployment.

The CHAIRMAN. You have been previously sworn by this committee, haven't you?

Mr. GREEN. No.

The CHAIRMAN. Do you solemnly swear that the testimony you are about to give before this committee shall be the truth, the whole truth, and nothing but the truth, so help you God?

Mr. GREEN. I do.

The CHAIRMAN. You may proceed, Mr. Green.

**TESTIMONY OF WILLIAM GREEN, PRESIDENT, AMERICAN
FEDERATION OF LABOR, WASHINGTON, D. C.**

Mr. GREEN. Mr. Chairman and honorable members of the committee, I am happy indeed to come and make my contribution toward the study you are making of a very important national question.

These are days of swift change which sweeps the surface of our economic living. These are years also of deep and far-reaching readjustments in our economy, some of which have been taking place over a period of many years but have made themselves acutely felt only recently.

After a decade of severe unemployment, economic instability, and of tremendous wastage of our resources, the American people have the right to ask: What are the real facts? What of the future? What provision can we make? The American people can rightly ask these questions, and it is the public responsibility to secure unbiased, impartial facts that would provide this vital information. And labor can ask these questions and seek this information with more justification than any other group.

The record of hearings of the Temporary National Economic Committee opened with a broad inventory of economic conditions in the United States since 1929. The committee properly began its investigation into the causes of idle factories and idle men. The facts summarized in this inventory brought out forcefully the changing nature of our economy and of its setting and the vast complexity of our economic problem.

Unemployment is the central problem in America today. The idleness of men, machines, and capital has been slowly eating into the very marrow of our economic organism. We cannot accept it or even any part of it as a chronic condition without admitting defeat. But in devising any means, no matter how effective, to bring about reemployment, we must fully recognize the impact of technological developments on production.

The crux of the problem we are facing today is the relationship of technological developments to employment opportunities. But before approaching this basic problem, we must first examine the outstanding features of our employment trends in a living, growing, changing national community. How has technological change affected the employed worker? What is its relation to labor costs? Have rising or falling wages speeded up or slowed down mechanization? How much is known of the net effect of industrial mechanization on employment? All these and other questions are of crucial importance to all men and women wage earners. I earnestly hope that an approach to more complete answers than we have today will grow out of the present investigation. Labor's future depends upon a full, equitable, and democratic solution of this problem, and labor's future is inextricably bound up with the destiny of our entire Nation.

Manpower is the greatest wealth, the richest resource, of the American Nation. The standard of our living depends upon the productive activity of our workers, skilled and unskilled—managers, mechanics, and day laborers; farmers and seamen; architects designing sky-

scrapers and miners burrowing into the bowels of the earth, or any others who take part in production of goods and services.

Our Nation is generously endowed with natural resources. Coal, oil, and precious metals, fertile soil covering fields, broad pasture lands, and lumber-producing forests, as well as life-giving rivers and streams, make this a country rich in resources.

To these we have added man-made resources. We have built cities and towns, we have constructed highways, power houses, and transmission lines. We have built dams and irrigated large areas of land, and have built factories and homes. Above all, we have built machinery and mechanical equipment for the use in production of goods and services and their distribution. All these man-made resources we have developed and perfected. But we must remember that it is from the productive work, the skills and the activity of men and women who perform their daily tasks on farms, in factories, in mines, in offices, and in hundreds of occupations that we derive our vitalizing strength for the development and intelligent use of our other resources.

When I speak of manpower as the most significant of our resources, I think of it in terms of experience, skill, and intelligence, combined with productive activity and the heritage of human knowledge, always expanding, which gives that activity direction. Manpower, however, cannot be thought of as a resource only—it cannot be separated from its human terms. A worker, no matter in what occupation, is a member of his family and a member of his community. He has obligations to himself, to his family, and to the community which he must fulfill. And so the community also owes a responsibility to him. As an individual, as a member of the family, and as a member of the community, he, as a producer, is entitled to his share in the return from the economic process. By all the tests, the man as a producer must be considered the source of our greatest wealth, and yet he, as the source of human labor, must clearly and for all time be distinguished from any commodity or article of commerce. This distinction was made, clearly and unequivocally, many years ago, because such was the sense and the will of the American people.

In discussing manpower as a resource of our Nation, it must also be pointed out that manpower which is not put to use is a perishable resource. Much has been written and said about the waste in the exploitation of our natural resources, but I believe these wastes are relatively insignificant when compared with the waste of trained labor forced to remain idle because the economic mechanism is hopelessly jammed. Ten million idle workers remaining unemployed over a period of time is an incalculable loss to our whole nation. It means more than the loss in potential national income due to the unemployment and the loss of earning power of such a large number of wage earners. Loss of skills caused by unemployment makes a scrap heap of their ability and experience and prevents them from making their contribution to the national growth. If we are in agreement that manpower is the most important resource of the nation, we must give our foremost attention to the utilization of manpower above everything else. For the very welfare of our Nation, labor must be given prior consideration. Full employment of labor is the first order of business of our Nation.

The CHAIRMAN. In other words, you feel, as many of us do, that the natural resources which are around us in such great abundance are

perfectly useless unless the people who inhabit the earth can use and consume those resources?

Mr. GREEN. You have put it just right, Senator; that is it exactly. It means nothing, it is of no consequence, unless we can develop and utilize the manpower of the Nation. Then it becomes a contributing force toward the promotion of our civilization, our social and economic well-being.

The CHAIRMAN. People are both producers and consumers?

Mr. GREEN. Producers and consumers.

The CHAIRMAN. And we must have the consumer if we are going to promote production?

Mr. GREEN. That is it.

Let us consider the facts surrounding the general problem of employment. Our population today is estimated at 131,000,000. Although our population is growing, the rate of growth has been steadily declining for a long time. In 1830 it is estimated that there were on an average 5 births per 100 of our white population, while in 1930 there were only 2 births per 100. This was to some extent offset by a decline in death rate and by increased longevity.

From the average rate of 19 per 1,000 at the end of the last century, the death rate dropped to 11 per 1,000 in 1930. The average annual rate of increase in population, which was $1\frac{2}{3}$ percent from 1900 to 1920, has dropped to less than 1 percent in the past decade.

(Mr. O'Connell assumed the chair.)

INCREASE IN AVAILABLE LABOR FORCE

Mr. GREEN. These facts are important to bring out because of the recent developments affecting employment. The number of persons available for the production of goods and services, who can also be described as persons with gainful occupations, may be secured from census data. When I speak of persons with gainful occupations, I do not mean only those employed; by this term, I include all men and women available for productive activity, employed and unemployed, farmers, professional workers, and self-employed. While our total population increased from 40,000,000 in 1870 to 131,000,000 in 1939, persons with gainful occupations increased from 13,000,000 to 56,000,000. In other words, while in 1870 persons with gainful occupations represented 32 percent of the total population, by 1930 this percentage had risen to 40 and by 1939 it is estimated to have come to about 43 percent of the total population.

Another significant fact bearing on employment is that on the average, our population is getting older. In 1880, about 38 percent of our population was under 15 years of age. By 1930, however, only 29 percent of the population was in that age group. While people on the average live longer, the proportion of the younger people has diminished. We have a larger proportion of mature and older workers today, and the continuation of this trend is indicated for the future. Inasmuch as persons with gainful occupations are mostly those over 18, this relative reduction over the 50-year period in the number of young persons provides one of the reasons for the increased proportion of persons with gainful occupations.

The important fact, however, is that a proportionately larger number of men and women have become available for productive activity.

Our imperative objective is to utilize their productive ability—not at any fixed level of production such as that of 1929 or of any other year, but at a level dictated by the considerations of the best utilization of labor in productive use in order to bring up the standard of living of workers engaged in useful production. Nor can the utilization of productive ability serve our purpose if it is done as a makeshift arrangement on a chronic basis. Productive ability of our workers must be utilized at such standards as will insure them a living compatible with the American standard of living and fulfill the obligation of the community to these workers as producers.

This growth in numbers of persons with gainful occupations gives a clear indication that the country can draw upon a proportionately larger reserve of available manpower now than was the case in the past. In tracing these changes we must give particular attention to the shifts in occupational groupings which have taken place in our total labor force. Considering the proportions of each broad occupational group, we find that since 1870 manufacturing and mechanical industries—which include also building trades, printing trades, etc.—comprise about the same share of those gainfully employed as they did in 1870. It is true that manufacturing and mechanical industries accounted for a growing proportion of persons with gainful occupations up to 1920 and that there has been a decline since 1920. The growth of our manufacturing production and the expansion of markets for our products accounted for a steady increase in the number of wage earners employed in manufacturing to 1920. Although between 1920 and 1930 the production expansion continued, employment during this period, as reported by the census, showed a slight decline.

In 1870 manufacturing industries accounted for about 17 percent of persons with gainful occupations. This proportion had increased to about 27 percent by 1920. From 1920 on the proportion of persons with gainful occupations employed in manufacturing industries was in a decline and by 1930 was only 23 percent.

The most outstanding shift in the economy as a whole since 1870 has been the decline in the number of persons who considered agriculture and its immediately related operations as their normal, gainful occupations. In 1870 nearly one-half of all persons with gainful occupations were attached to agriculture. It is estimated that today agriculture claims less than 20 percent of our total labor forces. At the same time there has been a marked occupational shift toward service occupations, with the largest proportional increase in trade and transportation.

It is clear, then, that the center of gravity of our economic machine has shifted and that adjustments have to be made or its most vital parts will be burned out and destroyed. Broadly speaking, distribution and service fields have to be given special consideration in dealing with employment opportunities under changing conditions.

A clear appraisal of the occupational distribution of all those who have productive qualifications, whether they are employed or not, is essential to our analysis of the problem. Equally important to us is a detailed knowledge of employment facts, and by that I mean facts revealing the actual employment situation. Although employment data have been greatly perfected since 1930 and are vastly superior to the prior information, they are still far from complete. Labor hopes that complete and adequate information on employment

wages, hours, and labor costs will in time be made available so that we would have a complete and continuous set of facts in order that we could study them, analyze them, offer solutions, and devise remedies based on realities.

Acting Chairman O'CONNELL. Mr. Green, may I interrupt you for a moment? How do you think that material ought to be collected?

Mr. GREEN. I think it ought to be collected under the statistical department of our Government, and that, I think, should be better set up so that the facilities would be more serviceable in order to collect that data.

Acting Chairman O'CONNELL. You mean the—

Mr. GREEN (interposing). Now, for instance, we speak in round numbers of 10,000,000 unemployed people, but there is no person in America who knows how many of those 10,000,000 are unemployed employables and how many of them could, perhaps, be classified as impaired unemployed employables, and then another number, another grade, perhaps, of really unemployed unemployables. Who can answer that question? Nobody. Now, shouldn't we have it in order to determine a great question such as you are studying?

Acting Chairman O'CONNELL. Yes.

Mr. GREEN. Now, that is what I mean. Better statistical service, more available facts and data, because, after all, we ought to make a clear diagnosis of our problem and then of the case before us, that would enable us to deal with it in a more realistic way, a more practical way.

Acting Chairman O'CONNELL. That would require a larger, probably better set-up organization in the Government to compile the material, and it would also involve a degree of cooperation with industry and labor, and so on, with those who come to collect the material?

Mr. GREEN. Labor and our State organizations.

Colonel CHANTLAND. Continuity and up-to-dateness are vital, I think.

Mr. GREEN. How's that?

Colonel CHANTLAND. I say that continuity and up-to-dateness are vital.

Mr. GREEN. Yes; continuity and up-to-dateness. It ought to be available continuously, right up to date, so that we could deal with the problem effectively. For instance, look how much better we could deal with unemployment if we had the groupings I mentioned.

Dr. ANDERSON. Would you include in the data to be collected similar adequate data on agricultural employment?

Mr. GREEN. Oh, yes; because as I pointed out, 50 percent, some 40, 50, or 60 years ago, were employed in agriculture, and now we are down to 20. Why is that, and what does it mean, and how does it come about? What are the facts? They ought to be assembled and made available.

Dr. ANDERSON. Just as employment data should be kept for both industrial and agricultural workers?

Mr. GREEN. Absolutely.

Needless to say, any estimates of total employment or any other basic facts on which our information is incomplete, made at a time when we are taking our great national inventory, must be accompanied by some reservations. Our attempts to compare the total non-agricultural employment in 1929 and 1939 are also subject to such reservations with regard to the 1939 estimate. The Bureau of Labor

Statistics' estimate of 33,686,000 employed nonagricultural workers in 1939 may not exactly represent the actual number of workers employed, but it does give us a range for the purpose of comparison. As compared with the 36,160,000 employed in 1929, this estimate indicates that roughly 2,500,000 fewer workers were employed in 1939 than in 1929 in such nonagricultural employments as manufacturing, mining, construction, transportation, utilities, trade, service, etc.

PRODUCTION AND INCOME SINCE 1929

Mr. GREEN. Now, in making any such comparison, it is important to determine, first, how 1939 production compared with 1929. First, let us compare the volume of production in manufacturing on a sample basis. While the 1939 production of nondurable goods (such as textiles, tobacco, paper, rubber, etc.) averaged only 4 percent below its 1929 average, the durable goods production (such as steel, lumber, shipbuilding, automobiles, etc.) for the entire year 1939 was about 22 percent below 1929. Between 1929 and 1939, the loss of employment in the manufacture of durable goods was more than 700,000, while in nondurable goods the decline was around 16,000.

Great losses in employment also occurred in construction, where between 600,000 and 1,000,000 workers had been displaced during the 10-year period. In transportation and public utilities, as many as 800,000 jobs were wiped out. In the combined fields of trade and service establishments, we note another decline in employment to the extent of 800,000 jobs.

While the Federal Reserve index of industrial production is the best available indication of the pattern of industrial production and its various branches, it is only the best sample, and does not by any means provide a complete picture. Probably the best clue we have to the relative volume of goods and services produced in 1939 is derived from the annual comparisons of our "national income produced." Our "national income produced" in 1929 was \$82,700,000,000. In 1938, our next best year, the income was \$71,900,000,000. In 1939, it was \$68,500,000,000. The meaning of the "national income produced" was fully described in a Senate report in 1934.

This concept was used in the basic studies on productivity by the National Research Project and has gained acceptance without serious challenge. It merely represents the net value of the goods and services produced, the result of which appear on the market place of our economy. "National income produced," in order to serve as a reliable measure of annual production of the quantities of goods and services, must be adjusted for the changes in the value of money.

I have just shown that the 1939 national income was approximately \$14,000,000,000 less than the record total of 1929, but now I want to point out that this 17 percent change took place at the same time with a 19-percent drop in wholesale prices and a 15-percent decline in the cost of living. Neither of these price adjustments is sufficient to make the correction precise, but it gives ample indication that the total quantity of goods and services produced in 1939 was very nearly the same as that of 1929. The same conclusion has been reached by the economic analysts of the United States Department of Commerce in their Economic Review of 1939.

Don't let this conclusion be taken to mean that if our 1939 production of goods and services was about equal to the previous all-time

peak of 1929, we were really as well off as we had been in 1929. We must not forget that our 1939 production had to provide food, clothing, housing, and service to 10,000,000 more people, and on a per capita basis we should have produced at least 7½ percent more of everything to equal the 1929 level. As it is our living standard is just that much lower.

But the fact with which we are especially concerned here is that our 1939 production about equaled 1929, and yet our total employment dropped some 3,000,000 below the 1929 employment level. The loss of employment of this number of workers cannot be charged up to production declines.

Of the total number of unemployed, which we estimated at 10,200,000 in 1939, some 8,400,000 represent the total increase in unemployed during the 10 years, as we started out with 1,800,000 jobless in 1929. Our estimate, of course, takes into consideration, together with all other elements. The fact that during the past decade some 12,000,000 people reached working age. Having made a generous allowance for increased school attendance and earlier retirement, we estimate that 5,300,000 people came to look for work, wanting to earn an independent living. The new job seekers, brought by population growth into the struggle to earn a living. Cannot be excluded from the count of those who must be provided with jobs.

Let us bear clearly in mind these facts: There were 10,200,000 unemployed in 1939. This represented an increase in unemployment of 8,400,000 from 1929. Employment in 1939 was roughly 3,000,000 below 1929 employment, and yet, the volume of 1939 production about equaled 1929.

At the same time, we must remember that, entirely apart from any changes in the methods of organization of production, standards and conditions of employment changed. Average hours of work in manufacturing changed from more than 48 per week in 1929 to less than 38 per week in 1939—a decrease of over 22 percent. Had the same workweek been maintained in 1939 as in 1929, our unemployment problem to day would have been much larger. Without making sweeping generalizations on a question involving the relationship of output to production schedules and other modifying factors, it may be merely pointed out that a production crew of 100, which is employed 48 hours a week, will put in 1,000 more man-hours of employment per week than when it is employed 38 hours a week. But with the shortening of hours from 48 to 38, these 1,000 man-hours make possible full-time employment of 26 additional men.

When labor raised its voice for the shorter work-week 7 years ago, it spoke for the employed and the unemployed workers alike, insisting that sound recovery must be accompanied by a full measure of re-employment. Through the application of principles of our proposal embodied for 2 years in the N. R. A. codes, through the ceiling placed on hours of work by the Fair Labor Standards Act, and above all, through collective bargaining. Labor has succeeded in averting a greater economic blight and a worse disaster than we have seen. If positive progress is to be made in resolving the persisting and deepening unemployment problem, further shortening of hours must be achieved in our industry and trade.

Considering the plain evidence that the shortening of hours since 1929 mitigated the unemployment situation to some extent, we still

have the stubborn reminder of a basic change in the speed of production. Although during the entire period, production passed through several drastic fluctuations, a simple comparison of 1929 and 1939 shows that a similar volume of goods was turned out with the use of fewer workers but also in shorter work time. To what extent can we attribute this to increased productivity, technological development, or specifically to the use of labor-saving devices?

INCREASED PRODUCTIVITY

Mr. GREEN. In order to measure changes in industrial productivity, we must measure changes in the amount produced per worker for a given unit of time. While a number of fragmentary studies have been undertaken recently, our information with regard to productivity is still far from complete.

One of the latest studies on the subject by Dr. Frederick C. Mills, of the National Bureau of Economic Research, reviews changes which have taken place from 1899 to 1929 and from 1929 to 1935. The measurements of productivity per worker per man-hour in manufacturing made available by Dr. Mills show that during the 30-year period ending in 1929, man-hour productivity had increased 125 percent. According to this estimate, the rate of increase in the volume of output per man-hour remained about the same from 1899 to 1919. During this time productivity measured on this basis increased about 24 percent in each 10 years. Between 1919 and 1929, however, this rate of increase rose sharply, being nearly doubled, as shown by the estimate for this decade of 46 percent. It will be noted that the number of wage earners represented in this estimate increased only 68.5 percent over the entire 30-year period. The figures just cited on the increase in the rate of productivity shows striking evidence that the post-war developments brought about changes in technology and greatly speeded up the rate of production. This jump in man-hour productivity registered in the 1920's explains the fact that in a decade of a rising manufacturing output, employment failed to increase proportionately. A substantial portion of the unemployment which already existed in 1929 must be attributed to displacement caused by these developments in the preceding decade.

According to Dr. Mills in the period 1929 to 1935, while employment in the manufacturing industries studied decline 31 percent below 1929, and production in these industries was 13 percent below 1929, estimated output per man-hour was 27.2 percent above the 1929 output.

Broadly similar conclusions were reached as the result of a detailed and painstaking study of productivity conducted by the National Research Project, in collaboration with several agencies and institutions. The index of output per man-hour for 59 manufacturing industries analyzed in this study rose from 69 to 100 between 1919 and 1929, and rose further from 100 to 124 between 1929 and 1936. In the 59 manufacturing industries considered, the rise in output per man-hour was thus indicated to be 24 percent. In substantial agreement with these conclusions is the recent study by Dr. Spurgeon Bell of the Brookings Institution.¹

¹ Spurgeon Bell, *Productivity, Wages, and National Income*, Brookings Institution, Washington, 1940.

It must be remembered, of course, that technological change as such does not necessarily mean displacement of labor in our industry in every instance. The increases in productivity are usually due to the installation of new improved machinery which yields a greater rate of production on the amount of investment. Greater productivity may also be due to better organization of production or to increased work requirement. In individual industries, we have seen mass tragedies of workers subjected to inhuman working conditions where, through "stretch-out" and "speed-up," every ounce of their energy is extracted in order to derive greater output.

Some of the equipment installed does not represent labor displacing equipment. Much of the machinery that has come into use has been supplementary to labor operations and has been used in addition to, rather than in place of, normal work activity performed by the labor force.

With these qualifications, however, it must be said that the major effect of technological change upon employment has been the displacement of workers through labor-saving machinery. The labor content of our basic products has been declining. When we note that the tobacco industry, including cigars and cigarettes, dropped 27,000 workers between 1929 and 1939 (when cigarette consumption rose 45 percent), we cannot pass this fact over by merely saying that this is due to the rapid introduction of machine processes for hand processes.

Nor can we pass over the fact that in industry after industry the introduction of the machine process has meant complete and irrevocable destruction of jobs. In the glass container industry, to use but one example, the glass bottle blower is a highly skilled craftsman. Years of apprenticeship and of day-to-day experience were necessary to build up the skill and dexterity required by the high standards of the trade.

In 1904 and 1905 the Owens machine was brought into the manufacture of glass containers, and, with later modifications, made the glass-bottle blowing process almost completely automatic. Whatever else the use of this machine has meant to the industry, it destroyed the individual and collective skill of some 28,000 craftsmen on whom the industry had depended for its output. For me that is the tragic development which has taken place in this technical development of modern industry, the destruction of skill, skill acquired just the same as the student acquires professional knowledge, skill that resulted in lifting the American family to a higher level of living, and then suddenly overnight that skill was destroyed and the level lowered because that skilled worker is no longer fitted for any other occupation except common labor. That, to me, is tragic.

Thus for each one of these technological changes labor is paying a terrific price—that is labor that paid that price, the skilled worker. The change comes suddenly, like a stroke of lightning, and the life-giving source of employment is withered and dried up for all time. In furniture manufacturing hand carvers, jig-sawyers, hand finishers, and other skilled workers have all given up their place in industry to machinery. In the tire industry, in the mining industry, in the railroad industry, in the shoe industry, I could tell you story after story of human tragedy and despair which would turn cold figures into the flesh and blood of human reality. But here I am concerned only with the total picture, and I want to impress upon you the national scope of the problem.

In doing this, I want to call your attention to a phase of the problem which I consider basic. It is often argued that any and all technological changes in production which increase production, although they displace labor, are of ultimate benefit to the workers because they ultimately increase employment. According to this argument, the initial reduction in labor force is merely a temporary effect of technological change, and the reduction in the price of the product made possible by the introduction of labor-saving machinery would widen the market and eventually lead to greater employment. It is important to realize that while this had held true in the past, there is no magic in this formula and it is unlikely that it will hold true in the future.

When textile machinery was introduced in England at the end of the eighteenth century, it made possible much cheaper production, and rendered unemployed some 600,000 weavers and other textile workers who used to make cloth by hand for the greater part of the civilized world. There was much rioting and much talk of permanent unemployment. Gradually textile machinery became an accepted fact and its use grew apace. Eventually the mechanical textile industry in England absorbed a larger number of wage earners than the original number of artisans who used to make hand-woven cloth and fabrics.

The use of cutting machinery and other power-driven devices revolutionized the dress industry not very many years ago, and while the machinery had displaced a large number of manual operators, the drastic reduction in the price of dresses, having brought the \$4.98 and the \$2.98 dress within the reach of women of low income, has expanded the market enormously and given rise to unprecedented growth of this large and important industry.

While all this is quite true, it is also true that in a number of industries new installations of machinery have appeared, driven by electric power, operated by electric controls with more than human precision, which in their operations call for no manual operations, no manipulation, or other human activity for which mass-production industries have to date required large numbers of semiskilled workers. In the operations of these completely mechanized plants most of the labor requirements may consist of a small skeleton maintenance crew of skilled mechanics and a negligible supervisory force. There may be a watchman, but even a sweeper is practically unnecessary because the machinery is installed in an air-conditioned building.

Although plants such as this are not yet numerous nor typical, they cannot be disregarded, and may prove to be an indication of things to come. The significant point about this development is that when you do away with the most of labor, it does not matter how cheap the product becomes, nor how great the demand for it, for the production and sale of that product simply is not going to give anybody employment.

TECHNOLOGY AND WAGES

Mr. GREEN. One of the important questions in connection with technological unemployment is the question of its relationship to wages. Whenever a question of general wage increase is debated, there is always someone to argue that by gaining a larger share in production returns through increased wages workers would eventually lose because management through the installation of more effi-

cient equipment would "beat" the increased wage and supplant workers by more productive machinery. It is extremely important therefore to examine the facts on the actual relationship of productivity, wages, and labor costs.

(Senator King assumed the chair.)

Mr. GREEN. A recent study by Spurgeon Bell shows that since 1919 to date productivity in manufacturing industries showed a steady increase over the entire period. Hourly earnings, having shown a slight increase during the 1920's, dropped sharply during 1929-33 and following the drop advanced more rapidly than productivity between 1933 and 1939.

Between 1923-25 and 1938, however, the rate of productivity per man per hour increased 44 percent, while hourly earnings increased only 18 percent. In other words, between 1923-25 and 1938, productivity increased twice as much as hourly earnings. As Dr. Bell points out, "In monetary terms, therefore, labor did not absorb all the savings arising from the increase of output per man-hour."

Another significant fact brought out by this analysis is that, while during the period as a whole man-hour productivity increased substantially and hourly earnings increased appreciably, unit costs were reduced by 17½ percent.

The figures I have just cited referred to manufacturing generally. It is interesting to compare these with the figures of some other industries. In railroads Dr. Bell's figures reveal a similar picture. Between 1923-25 and 1938 productivity rose 44 percent; hourly earnings, 19 percent; while unit-wage costs declined 17 percent.

In mining industries, however, the picture is even more striking. In this group of industries between 1923-25 and 1938 man-hour productivity rose 99 percent, or almost double. At the same time hourly earnings, after steadily declining for 10 years from 1923 to 1933, rose by 1938 only 8½ percent above 1923-25. This took place in the face of sharp reductions in unit-wage costs, which between 1923-25 and 1938 were reduced by 46 percent.

In the electric-light and power industry productivity rose during the same period 116 percent, while average hourly earnings rose 35 percent. Unit-wage and salary costs in this industry were reduced 31 percent.

Thus, in industries with widely differing proportions of labor costs to the total value of the product, increased productivity invariably outran wages. At the same time wage increases which took place neither speeded up the fairly constant rate of technological change, nor increased the operating costs of the industry as a whole.

The 1925 convention of the American Federation of Labor declared that "social inequality, industrial instability, and injustice must increase unless the workers' real wage—the purchasing power of their wages—is advanced in proportion to man's increasing powers of production." That is an unassailable fact. It is clear to me today in the light of the facts I have shown that the essence of our problem is that, while we have increased enormously our ability to produce, we have not increased the workers' real wages, nor the purchasing power of their wages, in proportion to this production.

Only this approach can enable us to deal at all effectively with the problem of job displacement which results from technological change. In our attempts to deal with the problem we must remem-

ber that these technological developments are one of several basic changes. I have emphasized the shifts in occupational distribution of our population. The shrinkage of production industries as an occupational field and the expansion of the distributive field of transportation, trade, and service industries gives some indication of the changing direction of the trend.

Technological development and industrial mechanization may in time completely revolutionize the methods by which goods and services are produced and our economic wants are satisfied. Our whole way of life may be changed. But it would be idle speculation at this time when our immediate needs are so urgent and so vital to muse on the possibility of the triumph of the machine over man.

The current rate of technological change has been fairly well indicated to us by the recent studies I have cited. We do know that the technological rate of displacement of labor is large. We do know that of the 3,000,000 difference between 1939 and 1929 employment a large portion, though probably not the entire number, have been displaced by increased productivity. There is no reason to believe that this rate of technological progress within the range of the past two decades will change substantially. To offset this tide of new unemployment and to channel those already unemployed into productive activity is the problem before us.

It is being said in many quarters, and with stubborn finality, that America as a nation has stopped growing; with no frontiers, with no new markets, with a population growing at a relatively slow rate, we must resign ourselves to the fate of economic stagnation. Now that is the language of the defeatist, and I cannot accept this defeatist philosophy because to me it seems not only false, in fact, but also treasonable to our entire American heritage.

Acting Chairman KING. As a great labor leader you ought not to accept that.

Mr. GREEN. Never, never, Senator. Never that. It is clear, of course, that in all industries and especially in manufacturing, we can achieve no substantial gain in employment without a marked increase in production and a further shortening of working hours. That is so we can distribute the amount of work available among a very much larger number of people. We must maintain our effort of gradual reduction in the weekly hours of work in order to attain this end. The question of achieving a large increase in production in order to gain full employment seems to have been the stumbling block of all of us in these past years.

We suggested recently that a \$10,000,000,000 increase in our national income would be sufficient to provide reemployment for the majority of the workers now unemployed. Considering that 93 percent of all families and single persons in America have incomes of less than \$3,000 per year, and that three-fourths of them have incomes under \$1,500 per year, we must realize that this is the income group that buys 78 percent of all consumer goods sold on the American market. The answer is clearly that with the release of the purchasing power of the wage earners, and through the maintenance of their real wages at the level necessary to sustain a rise in the national income, enough productive activity can be generated to achieve this reemployment. The question is how to release the flow of goods and services,

how to release the pent-up savings and investment funds to put our money, equipment, natural wealth, and manpower to work. We are now giving careful study to a proposal which, after further analysis and consideration, I hope I will be in a position to place before the country as a practical program for reemployment and as a realistic approach to our immediate problem.

It must not be forgotten that in addition to all other dislocations discussed, readjustments have taken place traceable directly or indirectly to war developments abroad. In some sections of industry, plant has been expanded beyond immediate domestic requirements. That is something we have got to think about. Pulp and paper industry has developed much new production in the South and Southwest, which is also attributable to technological advances. Shipbuilding, aircraft construction, and machine tools have been directly affected by war activity, with employment in these groups reaching extremely high levels. Other changes, such as the elimination of the tobacco purchases from England, have adversely affected certain groups. It is clear from this that the period of readjustment at the end of the European war will present many difficulties. The problem of employment opportunities already caused by industrial changes will be further aggravated by these special conditions. Organized labor calls upon industry and the public to take full cognizance of these developments so that a joint and representative consideration of changing conditions can be made nationally and so that standards would be devised national in scope. Only national consideration of employment channels, provided through public employment offices, and of other factors which enter into this complex problem can adequately approach a satisfactory solution.

SUGGESTIONS FOR DEALING WITH LABOR DISPLACEMENT

Mr. GREEN. Among the ranks of our unemployed a large number of workers have lost their jobs because of technological developments. Additional workers will lose their jobs or will be denied jobs because of further increase in technology in the future. After hearing all testimony I know that your committee will be in a position to reach broad conclusions with regard to the entire problem. In this general statement I want to leave with you these suggestions derived from my presentation.

1. More complete and detailed facts are needed, especially on employment, wages, hours, labor costs, and productivity in order to enable us to understand changing conditions.

That is what I dwelt upon a moment ago when you asked me the question. What we need is better statistical facilities so that all the facts ought to be assembled and presented to Congress, to the Nation. It is probably similar to a physician diagnosing the illness of a patient. First of all, he may not be able to lay his finger upon the cause, and it may be necessary for him to make a more scientific analysis, but finally he makes a diagnosis of the case, then he can apply the remedy.

Acting Chairman KING. Mr. Green, have we not at the present time—and I am asking for information—many sources of statistical information which pretty well cover the field to which you refer? Dr. Lubin of the Labor Department and his fine agency have done

most excellent work in providing statistics with regard to labor and costs, wages, and so on, and I know of other agencies which are furnishing us—I will not say complete and adequate information, but a vast amount of statistical information. Of course, I agree with you that we ought to have as nearly as complete information as it is possible to obtain, dealing with these complex questions of wages and hours, and so forth, to which you have just referred.

Mr. GREEN. Yes; the Department under Dr. Lubin is rendering excellent service, it is doing fine work.

Acting Chairman KING. I didn't know that Dr. Lubin was here when I made that statement. I just came in. I will not retract it, however.

Mr. GREEN. We all say that, whether he is away or whether he is here.

Dr. LUBIN. Thank you so much, Mr. Green.

Mr. GREEN. He is doing a fine piece of work, but I know he will admit, if you will put him under examination, that his facilities are inadequate. Of course, we depend perhaps on the census now that is being taken to assemble a lot of facts that we can analyze and study and consider. Just as I remarked a while ago, Senator, here we have in round numbers 10,000,000 unemployed, some say more, but where is the department in our Government that can tell us the classification of these unemployed, whether there are 5,000,000 unemployed employables and then another grade with so many million of partly incapacitated, and then perhaps a certain number of unemployed unemployables. They aren't able to go into that, they haven't got it yet. Don't you think if we could assemble those facts we could then find where each group properly belongs and how to treat and deal with each group separately.

Acting Chairman KING. We ought to have that information to make a proper distribution, if that is the proper term, of the unemployed and unemployable, the migrants, and so on.

Mr. GREEN. Yes; the cause of it all, why is it, the wherefore, what about it? How is this economic machine operating? What is it doing here?

Acting Chairman KING. Speaking of our physical health, we not only want a health chart, but we want a proper labor chart, a graph, to tell the causes of unemployment, the causes of dislocation, and so forth.

Mr. GREEN. Second, I suggest a further shortening of the work-week as essential to future reemployment, because we feel that the real solution for our unemployment problem is the reabsorption of these unemployed back into private industry where they will be producers of wealth and goods and will be consumers of wealth and goods. If the facts—and that is what we must deal with—show that we can't find work for all these people on, say, an 8-hour day, then we must face that issue courageously and make the adjustment so as to find them employment in private industry.

Third, increase of our national income by \$10,000,000,000 in order to make this reemployment in productive activity possible. A practical proposal for accomplishing this is being developed by the American Federation of Labor.

We are working on that and I hope we will be able to supply you with our recommendations on that in a reasonable length of time.

After all, it is a matter of buying power. We must try and balance the facilities of production with our ability to consume, or raise our market buying power to a higher level in order to consume, these goods that are constantly flowing from industry. In other words, establish an equilibrium. What is the use of producing cheap goods if nobody can buy them and use them? That doesn't count.

Acting Chairman KING. I take it that this committee will die in the not distant future, and if you have any suggestions along the line you have just suggested, I take the liberty of indicating you submit them as soon as possible to the chairman.

Mr. GREEN. I will do that. I hope the committee doesn't die.

Fourth, special consideration should be given to insure to productive workers their share in the return from technological improvements.

Fifth, exhaustive consideration to employment opportunities should be given on a national basis with participation of representative groups.

In conclusion, I want to express my urgent hope that through our common endeavor we shall succeed in devising a truly effective, cooperative instrument with which we could adjust the existing economic unbalance and bring our Nation back upon the upward path of economic rise. I sincerely believe that if we achieve real understanding of the problem and real willingness to cooperate, we can bring about full utilization of our wealth and full reemployment through our own efforts. I feel confident that the work of this committee will contribute much toward this end.

I don't know of any committee in Congress that is dealing with a more vital question than this one, and nobody will be able to adequately appraise the value of the service you are rendering society through this investigation.

Acting CHAIRMAN. Thank you very much.

Have you any question to ask, Dr. Anderson?

Dr. ANDERSON. One or two questions. First I wonder if the committee would care to ask any.

Acting Chairman KING. You had better get yours off first.

A. F. OF L. ATTITUDE TOWARD DISMISSAL WAGE

Dr. ANDERSON. We have had testimony as to the methods used by various labor groups to meet technological displacement in particular instances; such things, for example, as the dismissal wage. Does the American Federation of Labor make much use of the dismissal wage to alleviate the effects of displacement?

Mr. GREEN. Yes; yes, we have. We have utilized that in some of the relationships that have developed between members of the American Federation of Labor and employers. I can't recall at the moment the names of some industries in which we have jointly worked that out with the employers. It has afforded relief, temporary relief at least, and has helped tide the displaced worker over a serious part of his life.

Dr. ANDERSON. You look upon it, however—

Mr. GREEN (interposing). We have looked upon it with favor.

Dr. ANDERSON. But as a temporary affair?

Mr. GREEN. Temporary only.

Dr. ANDERSON. Does your unions seek to include in their contracts clauses dealing with technological change?

Mr. GREEN. Well, we have; yes, in some instances. We have provided in some instances for moving these who have been displaced from one section of a plant into another, so that they have been accorded some work. We have found it possible to do that among the younger workers, but it is not so easy where the workers are older, say 45 or 50 years of age.

Dr. ANDERSON. What do you think is effective for older workers?

Mr. GREEN. My point of view is that we have to move up the retirement age in order to adjust it with these economic needs. Here is an army of younger people coming in, displacement is going on, and we have to work out some plan by which the older worker may move out at an earlier age so as to afford opportunities for younger people.

Dr. ANDERSON. Do you think, Mr. Green, that labor should have a share with management in the solution of these difficult problems of technology, the rate of introduction of technological change, and factors of that sort?

Mr. GREEN. By all means. They are a matter of joint interest and each one should participate in the discussion of the problem.

Dr. ANDERSON. When you speak of shortening the workweek to spread employment, do you include also maintaining the weekly wage, or do you propose also to spread the pay?

Mr. GREEN. Well, no good would be accomplished if you merely reduce the buying power. The buying power must be maintained in order to prevent further unemployment. We have met that question, however, in a realistic way. Our position is that weekly wage rates ought to be maintained even though the hours of labor are reduced. That is in order to maintain a balance between buying power and production. But there have been particular cases where wage adjustments have been made in order to create opportunities for a larger number.

Dr. ANDERSON. Do you think spreading the work through reduction of hours is realistic, in the sense that it can be attained in the immediate future?

Mr. GREEN. It can be, but it will have to be done not in a revolutionary way, but in a progressive, practical way, so that the necessary adjustments can be made. Some industries are better suited to the change quickly, immediately; others probably would have to make adjustments before the change could be made.

Acting Chairman KING. I suppose, Mr. Green, war conditions abroad with their impacts and repercussions would affect our economic conditions, affect wages, affect industries, change the current of production; some streams, so to speak, are swollen, others are diminishing. That produces dislocation. We have to take into account those changes and can't establish a rigid rule now in the light of the world chaotic situation.

Mr. GREEN. The war situation is having a profound effect upon our economy. We probably don't realize it fully and completely, but it is. I am apprehensive over the reaction that will come when the let-down period arrives, when we will be face to face with a very serious problem.

Acting Chairman KING. Of course, the let-down period will more seriously affect, perhaps, the European nations.

Mr. GREEN. Oh, more seriously there, but—

Acting Chairman KING. I was going to say that even though it will affect them more seriously, it will have serious repercussions in our economy.

Mr. GREEN. Probably the effect on the European nations involved in the war will be one of the direct causes of the serious affect here.

Dr. ANDERSON. I don't believe your summary included any allusion to the youth problem, as we are learning to speak of it. I wonder if you will give us the viewpoint of the A. F. of L. on that.

Mr. GREEN. Well, I think I referred to that just a few moments ago. We have this youth problem, this growing army of young people coming in every year. Now, first of all, their needs must be met by broadening, perhaps, the activities of our Government just at the present moment. Secondly, I think we ought to move up the retirement age of older people. That is, we must not do that in a destructive way or a revolutionary way, but it ought to be a matter of study. Where should it be in order to take care of this army that is coming in? We ought to give special attention to the employment needs of the youth of the Nation. I think we have neglected that a little too much and have considered merely the general aspect of the whole situation.

But here would be, as I see it the older worker moving out and the youth coming in. That is a matter of study. I couldn't at the moment express what it should be or how it should be done but it is a matter for study and a problem that ought to be tackled.

Dr. ANDERSON. The group of educators who testified this morning stressed the importance of vocational education and guidance for youth. Do you agree with that position?

Mr. GREEN. We have consistently supported that. I think perhaps we pioneered in advocating vocational training and vocational education. We have our committees functioning cooperating with the agencies of Government in the promotion of that, but after all, that is merely equipment. The question, the big problem, is the job. How are we to find work for them, even after they are trained and are given a vocational education? That is the thing I am thinking about more than the other problem. As I mentioned a little while ago, take the glass bottle-blowing industry. Here we had an apprentice system, a highly skilled trade. Young boys, young men, came in as apprentices, just like the young high-school student entering college to equip himself for his life work. In comes the apprentice all inspired by hope and vision, and as a young man he learns his trade, as is provided for under our union rules. As you know, all these rules provide for so many apprentices.

And suddenly, over night, a machine is invented that is substituted for the skilled workers and the apprentice. Out they go. There is the hope blurred; that is a tragedy.

Mr. O'CONNELL. Mr. Chairman, I don't have a question, but with your permission I wanted to make one very brief comment about one statement in Mr. Green's statement. It has to do with his statement about the school of thought which has apparently resigned itself to the thought that we are in for a period of economic stagnation and

decline. I thought it proper for somebody on this committee to make a statement about it at this time, because the philosophy has been in some quarters attributed to some members of this committee, and I feel very strongly that those people have a mistaken impression, arising out of a misconception of what is really only an unusual awareness on the part of some members of the committee of the unusual seriousness of the problem. The fact that they have discussed the problems in not too optimistic a way has led some people to believe they subscribe to the theory that nothing can be done. It seems to me proper to say that there is no member of the committee who subscribes to the philosophy you mention in your statement. We, with you, are inclined to believe that while the problems are difficult and apparently becoming more so, there is nothing constructive about saying nothing can be done about it.

Mr. GREEN. I am glad you brought that point out, because I say to you truthfully that I never had heard of any member of your committee assuming a defeatist attitude.

Mr. O'CONNELL. I understand that.

Mr. GREEN. I wouldn't want you to think that that was made as applicable to anyone. I get it out among my own people. I think it is perhaps due to the pessimism of the people. They probably sink down to a low point of discouragement sometimes, but none of us, no thinking person, can ever accept such a philosophy as that in America with its inexhaustible resources.

Acting Chairman KING. Are there any more questions? Mr. Green, we are very grateful to you for your message.

Mr. GREEN. Thank you for the opportunity of coming. I hope I may have made a little contribution toward your study of the subject, and I will be glad to cooperate any time in helping you along.

Dr. LUBIN. Mr. Green, may I say I think I am expressing the opinion of the committee that we are all going to wait with bated breath for your memorandum on the \$10,000,000,000, and I suggest to the chairman that we make arrangements now to leave the record open at that point so that when this memorandum does come we can get it in. We want it badly. We will need it.

Mr. GREEN. I have raised your hopes, you see.

Acting Chairman KING. The only difference I have with Mr. Green is that it ought to be more than \$10,000,000,000, and with our inexhaustible resources and our great manpower and technological skill, there is no reason why we should not get, with some degree of normality, to a \$100,000,000,000 or \$110,000,000,000 productive period. America doesn't confess any defeatism.

Are there any other witnesses this afternoon?

(The witness, Mr. Green, was excused.)

Dr. ANDERSON. Mr. Chairman, the next witness for today is a Government expert, Dr. J. C. Wright, Assistant Commissioner of Education, in charge of vocational education, who is speaking on the topic, Vocational Education and the Future of Workers Old and Young. Dr. Wright has not been before the committee.

Acting Chairman KING. Dr. Wright, do you solemnly swear the testimony you shall give in this hearing shall be the truth, the whole truth, and nothing but the truth, so help you God?

Dr. WRIGHT. I do.

TESTIMONY OF DR. J. C. WRIGHT, ASSISTANT COMMISSIONER FOR VOCATIONAL EDUCATION, UNITED STATES OFFICE OF EDUCATION, WASHINGTON, D. C.

Acting Chairman KING. Proceed, Doctor.

Dr. ANDERSON. What is your position with the United States Office of Education?

Dr. WRIGHT. I am Assistant Commissioner for Vocational Education.

Dr. ANDERSON. Your duties, then, are in the definite field we have been discussing, that of vocational training, guidance, placement of vocational trainees?

Dr. WRIGHT. That is correct. In my division we administer the acts of Congress known as the Smith-Hughes Act, the George-Deen Act, and other acts relating to vocational education.

Dr. ANDERSON. How long have you been engaged in such work?

Dr. WRIGHT. I have been in education for 43 years, the last 28 of which have been in vocational education and the last 23 of which have been with the Government. Since 1917 I have been in this present work, under the Smith-Hughes Act.

Dr. ANDERSON. And you have published in the professional field of vocational education?

Dr. WRIGHT. Yes, sir. I have published a number of books, some dealing with technical phases of the program and others with professional phases of administration, supervision, and training.

Dr. ANDERSON. I suggest, Dr. Wright, that you highlight your prepared statement as much as possible, in order to see if we couldn't encompass it in the hour that is before us.

Acting Chairman KING. Proceed as best you may to carry out the suggestion.

Dr. WRIGHT. I will be glad to do so.

Mr. Chairman, I beg your indulgence in the beginning to express my appreciation of two remarks that were made earlier in the day, one that was made by the chairman himself with respect to the importance of securing, on the part of our public schools, an appreciation of the dignity of labor, the willingness and right of every man to work whether it be at a highly skilled job, a professional job, or a job of common labor, so long as it is honest work. I believe that we in the school business, and the public, should give the same respect to the worker that we do in the more highly skilled and professional occupations.

My second comment, if you will permit, is to compliment the previous speaker, President William Green, of the American Federation of Labor, on the very wholesome and helpful data which he has presented to us, and which we in the field of vocational education will take occasion to study and digest.

A century ago the question of training men and women for work was not in any sense a national problem. Boys and girls in their early years were quite naturally inducted into the work of the family, both as regards to the upkeep of the home and the prosecution of the main business of the father and mother. Practically 90 percent of the usefully employed population was engaged in farming, lumbering, mining, and fishing. Manufacturing was largely a series of activities

which were either a part of the household routine or closely connected with the household. Large families of children were assets rather than liabilities, because there was neither public sentiment nor public law against having these children participate in such activities.

William S. Knudsen, president of General Motors Corporation, has well stated the educational value of work experience, when he says (Trained Men, vol. XX, No. 1, 1940, p. 4, International Correspondence Schools):

The pioneers were men of little education. So were the immigrants. Consequently, there grew up a great reverence for book learning. The man who made his living sitting at a desk, wearing a white collar, was looked up to and envied. His life was easy, clean, "genteel." He seemed of a higher social class.

From this came many good things. It provided the urge for universal education in America. It gave every American mother the ambition that her child should have "the highest possible education."

But maybe we have gone a little too far in our reverence for book learning; maybe in our concentration on that we have forgotten other things which are just as important. This is the knowledge of how to work with our hands, how to create with practical skill.

I am not belittling education. What I am trying to say is that a person educated entirely through books is only half educated. There is a kind of practical knowledge and good sense which can flow into the brain only through the use of the hands.

What to do about it? Well, I think all our schools should put more emphasis on training in manual skills, give more opportunity for the youngsters to test the theories they learn in actual practice, let them compete with one another in building useful things. You can tell a boy what a pump is; but if he gets a pipe, and, by means of a cork on a string, draws water up through that pipe, he really understands what a pump is.

Today, the entire scene is changed for a large part of the public. Even in present-day rural communities most of the home-manufacturing activities have disappeared, and the production formerly thus supplied now comes from highly concentrated and highly specialized industrial concerns which are far removed from the home of the worker who participates. During the period of the development of this highly complicated industrial and commercial system, the general tendency has been to depend upon the facilities still existent in the industries themselves for training the workers. At the same time, large dependence has, until recent years, been put upon foreign countries for the supply of skilled workers in the more generalized trades.

It is safe to say that at the present time a very large percentage of all those who are working in industrial and commercial occupations have received their training "on the job" either by the "pick-up" method, by the "show-and-tell" method through fellow workmen, through organized instruction carried on by the industry itself, or by some combination of these methods. Although there are no statistics available that show conclusively the relative percentage of such workers who have been trained through the unorganized type of training and the percentage trained through the organized type, it is safe to say that many more have been trained through the unorganized type than through the organized type of training. The most prevalent of the organized type of plant training are the vestibule school and apprenticeship.

THE VESTIBULE SCHOOL

Dr. WRIGHT. The vestibule school is usually operated by an individual plant. Its purpose is to give novices in the shortest time possible, sufficient training to enable them to take their place at a machine

in an assembly line, or at a hand operation and perform skillfully enough to avoid spoilage—of machine, of raw material, or material in process. This type of training is suited to a narrowly specialized operation which can be taught in a relatively brief period of time and is practicable only in plants that use comparatively large numbers of workers in the various processes for which training is given.

Whenever possible, operatives being trained in a vestibule school are paid on a piece-work basis. This means that the training is, in most instances, given on the workers' own time. Recent interpretations of the Wage and Hour Administration are aimed at reversing this situation and requiring the training to be given on company time.

Apprenticeship, as it developed in the European countries and as it existed in the early industrial days in this country, practically insured an employer or master the services of an apprentice for many years after he attained his journeymanhood. It also assured the apprentice of employment by the master usually as long as he was a faithful worker and desired to remain with his master.

Apprenticeship included not only instruction in the manipulative skills of the trade, but also in the necessary related technical instruction which 50 years ago was not extensive, but which has increased until, at the present time, a real craftsman in the skilled trades is the possessor of a wide range of technical knowledge concerning tools, materials, mathematics, science, drawing, and so forth, basic to the application of the skills inherent in the trade.

Formerly the master was also responsible for teaching the apprentice to use the basic tools of education, namely, reading, writing, and arithmetic. Moreover, he was responsible for the social, civic, and religious training of the apprentice.

With the development of the large corporation and the wide separation of the actual employer from the journeyman worker and the apprentice, there has been an increasing narrowing down of the responsibilities of the master to the present-day situation in which the master, as a usual thing, feels responsible for giving the apprentice an opportunity to acquire only the manual skills connected with the trade.

Recent trends in social legislation and social development have supplemented the increased technical requirements of the trades to the extent that the training of apprentices, at the present time, is quite generally considered acceptable only when there is opportunity for the apprentice to acquire skill not only in the manipulative operations of the trade, but also the related technical knowledge.

Some programs of apprenticeship carried on by individual companies include not only manipulative practices on the job but also classroom instruction in the related knowledge by instructors hired for that purpose by the company. In other instances, cooperative relationships are set up with schools, usually public, although sometimes private, in which the related technical knowledge is offered in the school at public expense.

The inherent difficulties in apprenticeship, at the present time, are, in part, due to the high degree of division of labor and consequent specialization, and, in part, due to the general restiveness of the American workman and the lack of close employer-employee sympathy and coordination.

In many instances, an apprentice is taken on with the understanding that he will be given an opportunity to acquire the skills necessary in the various operations and different classes of work of the whole trade.

The economics of production are such, however, that in order that the employer may get a return on the apprentice commensurate with the wage he has to pay, he breaks him in on a single operation or a narrow range of operations of the trade; makes him, in a comparatively short time, actually productive; then keeps him on this narrow range of operations because he is productive. In other instances, the apprentice is used as a helper to save the time of the more highly paid journeyman. In either instance, the apprentice fails to acquire the basic skills necessary in the whole range of operations in the different branches of the trade.

The Federal Committee on Apprenticeship is promoting the idea of a written indenture which will contain a list of the operations to be taught the apprentice and the class of work he is to be taught to do. For the purpose of securing conformity to the agreement, local advisory committees will be expected to supervise the work of the apprentice to the extent of seeing that he gets the all-around training that is specified in the indenture. The obvious way to overcome the handicap which tends to make the employer use the apprentice either as a "fetch and carry" man for the journeyman or as a specialized operator, is to see that the apprentice, before he is put on as an apprentice or during the initial steps of his apprenticeship, has an opportunity, through organized instruction either in a company school or in a public school, to be taught the basic operations of the various branches of the trade. This is considered to be the legitimate function of what is known as the "all-day school." So far as the related technical instruction is concerned, it is now quite generally recognized that this is to be given in the school. This instruction may be designated preapprentice training.

The Federal Committee on Apprenticeship advocates and requires, for an approved apprenticeship program, that arrangements be made to provide for at least 144 hours of instruction per year in related subjects for each apprentice.

The foregoing relates very largely to organized programs of apprenticeship. By far the greater number of persons who have gone into a shop as novices and have later become journeyman have become so not through organized training but through a program of unorganized training which usually consists of a period of service as a helper plus a period of service as a "two-thirder and improver," or a job with some similar terminology which means a stage between that of helper and journeyman and the stage where the learner is allowed to use the tools and machines of the craft under the supervision of a recognized journeyman. The labor unions by and large are securing the discontinuance of the helper as a recognized worker, presumably with the hope that, with the disappearance of the helper and the appearance of common labor to do the fetch-and-carry work for the journeyman, it will be possible to organize and build up a system of apprenticeship.

PRIVATE SCHOOLS

Dr. WRIGHT. Private schools are of two kinds. The endowed schools are the result of the interest of some individual in the problem of training for the skilled trades. The individual usually provides a building and sometimes provides an endowment which will, in part, support the program of training. In a few instances, these schools have maintained the original purpose of training of a trade type. In many other instances, however, these schools have aspired to what they considered to be higher levels of operation and have become technical institutions, junior colleges, and colleges of engineering. For the most part, these schools have been pioneers in the field and have done much to arouse interest in training for the skilled trades and have tried out various methods of teaching and types of equipment. So far as the numbers trained in these schools is concerned, they have been and are negligible. By far the greater number of private schools are the ones which have been and are being operated for profit. In quality these range from some of the best trade training in the country to those which are nothing more or less than a racket. We have no means of knowing the numbers enrolled, but, on the basis of experience of those schools which must be certified by State departments of education before they are allowed to operate, we know that the numbers run up into the hundreds of thousands and that the money paid to them runs up into millions of dollars.

These are the schools of air conditioning, refrigeration, Diesel engine operation, auto mechanics, airplane mechanics, radio mechanics, and numerous others. This type of school flourishes in the heyday of the development of an industry. They make all kinds of promises and, all too frequently, fulfill none of them.

In this connection, it might be pointed out that the correspondence schools of this country are also connected with the program of training for and in the skilled trades, though, as a usual thing, they do not offer instruction in the manipulative operations and usually do not pretend, at least in the correspondence part of their program, to teach manipulative skills.

PUBLIC SCHOOLS

Dr. WRIGHT. During the past 20 years, there has been a remarkable development in the field of training for and in the vocations connected with industry, agriculture, and business, particularly the distributive occupations. I will not take the time to rehearse all of the aspects of this program except to point out the importance of the all-day trade preparatory industrial school in its relation to the development of a sound apprentice-training program which will fit in with modern industrial and economic conditions and, at the same time, afford real apprenticeship. And second, to point out the importance of the so-called diversified occupations program as a supplement to an apprentice-training program, particularly insofar as it relates to opportunities for training for the skilled trades in the smaller communities which could not of themselves afford to support a day trade-preparatory school, and for whom there is no free instruction offered in a State or regional school of the trade-preparatory type. The first exhibit is a description of the diversified occupations program as pre-

pared by a member of the trade and industrial education staff of the United States Office of Education.

(The document referred to was marked "Exhibit No. 2719" and is included in the appendix on pp. 17486-17488.)

Dr. WRIGHT. In connection with the Federal-State aided program of vocational education, there are a number of facts which might be pointed out:

1. The present agricultural education program makes use of the home opportunities for education and ties up the school instruction with a series of home projects carried on by the boy on the home farm but under the joint supervision of the teacher and the parent. This and the home economics program of a similar nature is one of the noteworthy attempts to preserve educational opportunity that still exists in the home and on the farm. (See "Exhibits Nos. 2720 and 2721" for statistics on these programs.)

2. The trade and industrial education program was apparently not designed by Congress to afford opportunities for training of a trade-preparatory type except for those occupations which require a relatively long period of training. The requirements are that the school shall be in session at least 9 months of the year and 30 hours a week, and that the instruction should be for those who are preparing to enter upon a trade and industrial pursuit. (See "Exhibits Nos. 2720 and 2721" for statistics on these programs.)

3. The trade and industrial education enrollment in part-time and evening schools is nearly twice that of the all-day preparatory school, which means that the Federal-State aided program reaches more workers already employed in the trades than it does those who are preparing to enter upon a trade. It is quite probable that one reason for this is a recognition on the part of workers of the necessity of keeping abreast of the time during an era of unprecedented technological development. This will be discussed again under another part of this testimony.

4. It should be remembered that the country, as a whole, has not as yet accepted the philosophy that education at public expense should be available for adults. One of the first activities to be eliminated by a community in a period of economic stress is schools and classes designed primarily for adults. Comparatively few of the communities of the country maintain educational programs aimed primarily to meet the needs of adults.

(The documents referred to were marked "Exhibits Nos. 2720 and 2721" and are included in the appendix on pp. 17489-17492.)

Dr. WRIGHT. It is assumed that the terms "retraining" and "rehabilitation," as used in this testimony, apply only to persons who have worked successfully at some occupation and, in some instances, are still working successfully at an occupation, but in other instances, have been forced to leave the occupation and must be rehabilitated and retrained for some other occupation.

There are a number of factors which enter into the possibilities of retraining and rehabilitation and that modify the methods used in retraining. In general, it may be said that the factors which bring about conditions which make retraining necessary are the age or physical condition of the individual, and the technological changes that have occurred, are occurring, or probably will occur in the occupation in which the person is engaged or has been engaged. In

general, it may be said that retraining has to do with two groups of workers—those who are still employed and those who are unemployed.

RETRAINING FOR THE EMPLOYED AND UNEMPLOYED

Dr. WRIGHT. The old saying, "An ounce of prevention is better than a pound of cure," applies in this situation. If we can foresee the situation of the future and take steps to help an individual, put him in a position that will enable him to avoid unemployment, we have done much more for him and at less cost than would be the case if we waited until he became unemployed and then tried to retrain or rehabilitate him for reemployment.

Depending upon the type of work at which a man is engaged, we can foresee to some extent the age at which he will probably become unemployed even if the company for which he works stays in business and considers his work satisfactory. Whether or not it is a matter of public knowledge, it is certain that some concerns try to avoid retaining the services of an employee beyond a certain age. In some types of occupations it is impossible for a worker to continue beyond a certain age, for such reasons as partially disabling accidents, failing eyesight, loss of fine muscular control, and numerous other causes associated with occupational hazards and age. In some occupations, technological changes come about which make the position unnecessary and it ceases to exist. Some workers engaged in piecework are certain to have their earnings decrease when they reach a certain age. With this type of individual it might be possible to get him established in a small place where he could supplement his industrial income with a small contribution to the larder of the family from a garden and chickens.

It is possible for some of these workers to build up a small business on the outside, either with a service station, a roadside stand, a paper and magazine business, or other small entrepreneur undertakings. In the case of technological changes as they appear on the horizon, it is possible to offer courses of instruction in evening schools which will enable the worker engaged in one occupation either to supplement his skill in that occupation or change to a closely related occupation. Examples: The steam engineer who can readily become a Diesel engineer, or even the operator of an electric engine. The pressman who has had experience on the cylinder press to be trained to run a high-speed automatic press or platen press in connection with which it would be unnecessary for him to lift the heavy forms that are used on the cylinder presses. The watchmaker or watch repairer, because of failing eyesight or muscular control, may become an instrument maker or instrument repairman, or even a radio repairman. The plumber or the sheet-metal worker who learns to use a welding torch or arc. The telegrapher who becomes a radio operator. Every employer knows that, other things being equal, it is better to retrain an employee than it is to fire him and take on a new employee. Particularly is this true if the company has an indemnity company policy, and if the job which the employee holds is governed by this policy.

The steam engineer on the railroad who learns how to operate the Diesel engine knows the policies of the company, knows the personnel, knows the procedures, knows the road, and in all respects is everything that is signified by the term "trusted employee." It is more economical

to capitalize these assets rather than to teach all of these things to a new man, however competent he might become as a Diesel-engine operator. In other words, retraining of employees to remain in the service of an employer reduces the cost of labor turn-over and conserves the wages and the morale of the employee who otherwise might be forced into the ranks of the unemployed.

Training costs increase with the amount of training to be given to an employee. It is, therefore, general practice in good adjustment programs to attempt in any retraining to salvage all of the fine old skills and knowledge which can function in a new type of employment. When retraining is to be given, it is also the usual practice to find a new job which is as closely related as possible to the job formerly held by the trainee. The general morale of any company is strengthened by the knowledge among the employees that it is the policy of the company to meet the demands arising through technological changes, and to retrain those already employed rather than to fire them and hire others who have the new skills or knowledge required.

The evening-school program should be built, to a large extent, upon newly developed and developing requirements of industry in the way of new skills and additional knowledge.

Much of what is said about the economy of retraining the employed may be applied to retraining of the unemployed. It has often been said that retraining of the unemployed will not in any sense reduce unemployment because the retraining of an unemployed man makes him ready to take the place of an employed man. This is not entirely true because, when the unemployed man is retrained to start a small business of his own or to render personal services which are ordinarily performed by the individual himself, there is no replacement of an employed person. The older employee, who is retained to operate a news, candy, and general notion stand does not necessarily replace someone else who is already operating such a stand. It may be said that the business he gets will be taken away from some other entrepreneur who is already operating. On the other hand, experience shows that increasing the number of salesmen does not necessarily mean merely increasing the amount of business taken away from some other manufacturer. It frequently means increasing the number of persons who purchase certain commodities. Certainly the rendering of personal service which ordinarily is performed by the individual himself is not displacing another worker.

Although it may not exactly be called retraining, consideration should be given to the offering of opportunities for those who are unemployed to keep up their level of competence during the period of unemployment; opportunity for the stenographer to keep up on shorthand speed, for the concert singer to keep "in voice," and for the machinist to maintain skills formerly used, to brush up on skills not so frequently used, or even to acquire new skills.

In the present industrial condition, many skilled mechanics have found themselves forced into positions of specialization on the job in which they have little opportunity to use more than a narrow range of the skills belonging to the old trade. Before these skills disappear entirely, it would appear to be economical to exercise these skills with a view to extending opportunities for employment.

At this point it should be recalled that the number of persons engaged in industry, who are not working at skilled occupations but rather at

semiskilled or unskilled occupations, is probably at least twice the number engaged in skilled occupations. In this testimony no attempt will be made to discuss whether more or fewer private schools should be encouraged. The testimony will deal entirely with the need for and methods of establishment of a larger publicly supported vocational education program.

THE NEED FOR A LARGER VOCATIONAL PROGRAM

Dr. WRIGHT. There are about 6,000,000 young persons enrolled in public 4-year secondary schools at the present time, of whom slightly more than a million are graduated annually. From 30 percent to 35 percent, or more than 300,000, of these high-school graduates enter colleges or other post-secondary schools. Yet the major portion of the secondary-school programs is built upon and consists mainly of subjects aimed at meeting college-entrance requirements. There are those who would say that an increase in the vocational-school facilities would offer these young persons a better opportunity to prepare themselves for their future occupations than does the present academic college-preparatory course. This is probably true, but an increase in the present vocational-school facilities with the retention of the present aims of the day vocational school would not be a complete solution of the problem because the present-day school facilities aim to prepare young persons for advantageous entrance into the skilled occupations only.

It is a generally accepted fact among those experienced in the field of vocational education that training for a skilled trade is not the best opportunity that could be offered to the young person who eventually is to find himself engaged in unskilled or semiskilled work. On the basis of actual experience, no one at the present time can say what the best training would be for this great group that probably will be earning a living in the semiskilled and unskilled occupations, but it is perfectly safe to say that there is some education on the secondary level that would be more satisfactory than either the present unit trade courses of the day trade-preparatory vocational school or the academic college-preparatory course.

The question may be raised as to whether or not it is possible to increase the number of young persons who will be prepared to enter skilled trades, and the answer to this is to look into the present field of occupations and we discover that not more than 20 percent of all the persons who are gainfully occupied are employed in occupations which require training beyond high school, at any rate that require professional training of a college level. That approximately 25 percent of the persons already gainfully employed are employed in skilled occupations, including the skilled occupations in business and skilled occupations in industry.

The differentiation made here between professional occupations and skilled occupations is that professional occupations require university, collegiate, or technical preparation of from 3 to 8 years beyond high school. A skilled occupation is one in which, to succeed, it is necessary to have either on the job or in school, or through a combination of on-the-job and in-school training, 2 to 4, or more years of combined school and work training.

The question naturally arises: How is it to be decided which individual shall take the college-preparatory course, which shall take

the courses leading to the skilled trades, and which shall take the more general courses that aim to prepare for employment in occupations, the specific preparation for which will be largely learned on the job? The best available answer to this is that a period of general education of an extensive type be offered to all pupils at the beginning of the secondary school period, and that all pupils continue in this general education program until they have demonstrated that they are qualified, through aptitudes, interests, abilities, and desires, to branch off either into special fields leading to professional work or into special fields leading to skilled occupations. The extent to which this general course for all pupils should permit of emphasis in any direction would depend upon a number of factors which need not here be discussed. The fundamental idea of this period would be discovering, or rather helping the individual to discover, the kinds of instruction best suited to him as an individual, taking into consideration his past experiences, present assets, and future opportunities. His instruction should function as a springboard from which he may make up his mind as to the occupation he wishes to follow.

The probabilities are that, in view of the economic and occupational situation, about 20 to 25 percent of the pupils should find themselves in the college preparatory course, about 10 to 25 percent in courses aiming at the skilled trades, and at least 50 percent in the more general type of secondary education.

We are concerned here primarily with the 10 to 25 percent aiming at the skilled trades and the phases of the work for the 50, or more, percent that look toward general occupational competency. From the sheer standpoint of numbers, there is at the present time far too small a number enrolled in the vocational courses looking toward the skilled trades. In the Federal-State aided program at the present time, there are about 200,000 pupils enrolled in day trade-preparatory industrial schools, and about 250,000 in the all-day agricultural schools. Of this latter number, certainly fewer than one-half expect to be engaged in or will be engaged in wage-earning occupations other than farming (entrepreneur), so that it is safe to say that not over 5 percent of all the pupils enrolled in secondary schools are enrolled in federally aided vocational courses other than home economics. Even if we were to make a liberal interpretation of what might be called "vocational commercial courses" looking toward employment in skilled occupations, less than 10 percent of the pupils now enrolled in secondary schools are enrolled in vocational courses aimed toward the skilled occupations.

This means that perhaps 350,000 of the 6,000,000 high school enrollees go to college or other post-secondary schools, and perhaps 600,000 are trained to enter the highly skilled trades and commercial pursuits—a total of less than one million, or, roughly, 15 percent of the total high school enrollment. This leaves 85 percent who leave high school before graduation or who receive a general academic education of a type that may be described as a more or less modified college-preparatory training, but without specific vocational value.

What has been said under "Economic Potentialities of Vocational Retraining" makes it evident that the present facilities in extension training, available to those employed in wage-earning pursuits, is

pitifully meager. There were about 49,000,000 "gainfully occupied" persons at the 1930 census, and our evening and part-time extension training program reaches about 1,000,000 of these, counting in farmers and homemakers who comprise about one-half of the number reached through the evening and part-time extension courses.

If we are to stabilize employment which has come about through technological changes, our greatest hope is in the evening and part-time trade extension school. Whether these extension opportunities be offered by the public schools, by the Y. M. C. A.'s, Y. M. H. A.'s, Knights of Columbus, churches, or private agencies, it is apparent that the public program must be extended beyond the confines of a few larger urban centers, and it must have much more diversified offerings than does the evening school of the present. The general public must be converted to the idea that educational opportunities for adults are as much a part of the public program as are educational opportunities for youth.

It should be noted that the statistics here quoted are for high schools over the country, large and small. They must be discounted by the fact that we continue to conduct many small secondary schools with enrollments of from 10 to 100. Of the Nation's 23,000 high schools, 50 percent have enrollments of fewer than 125 pupils; 75 percent enroll fewer than 250 students. Thus, three-fourths of secondary schools have little possibility for vocational training other than in agriculture and home economics.

These data on size of high schools must be distinguished from the proportions of the total secondary school population who attend small schools. The 1930 census showed 95 cities with populations of 100,000 or more, or 31 percent of the total population. There were also 284 cities with populations of from 25,000 to 100,000. Both classes of cities thus comprise more than 40 percent of the total population. It is clear that approximately 100 cities should be able to provide complete and highly diversified vocational programs, and that an additional 300 cities should be able to maintain limited vocational programs of a high order of effectiveness. There remains more than 50 percent of the total population resident in communities of fewer than 25,000 inhabitants, of which perhaps 45 percent are rural in the sense of less than 2,500 population. Unless large-unit (county, region, or State) vocational training institutions are set up under State-planning and State-Federal support, at least half of our high school youth can receive no formal vocational preparation other than that in agriculture and home economics. It is also clear that diversified occupations programs in trade and industrial and in distributive occupations offer about the only solution for vocational education in medium-sized communities.

HOW A LARGER VOCATIONAL PROGRAM SHOULD BE ESTABLISHED

Dr. WRIGHT. 1. Apprenticeship should be made a major activity of industry through and with the support of Federal and State Governments. Preparation for apprenticeship in preparatory courses should be recognized as a part of a training program. Through the development of such programs as the diversified occupations program and the establishment of State, regional, and county schools, opportu-

nities for such preparation as well as for extension training opportunities for those already employed should be made available to every section of the country.

2. The secondary school, as its main objective, should direct its education to the preparation of young people for citizenship, economic competency, physical well-being, social integration, and the fullness of living. This will mean new subject matter, new objectives, changed administrative policies, and, above all, a new attitude on the part of the general public toward the secondary school as the stabilizing influence of the country. It also means a secondary place for the college preparatory academic course in its highly specialized role of preparation for college. It will mean an adaptation of buildings, through suiting new building programs to new purposes, and reconstruction of present buildings and equipment to meet new needs. It will mean specific education on the part of the secondary school as to the placement and follow-up of students either graduating or leaving the school before graduation. To the extent that the school modifies its practices in the light of what happens to its pupils after leaving school, it will be successful.

3. Teacher-training institutions will need to adopt a new philosophy, new points of emphasis, and new methods of procedure to meet the changed conception of this type of secondary school.

INDUSTRIAL TRAINING

Dr. KREPS. I notice in your first recommendation you say, "Apprenticeship should be made a major activity of the industry through and with the support of Federal and State governments. Preparation for apprenticeship in preparatory courses should be recognized as a part of a training program."

(Mr. O'Connell took the chair.)

Dr. KREPS. Would you like to elaborate for us just how the Federal and State Governments' support would be given to an apprenticeship program; in what industries you would establish it; in what centers you would establish it? You have been working with this for a long time.

Dr. WRIGHT. I would establish apprenticeship in practically every skilled trade and occupation, many of which are not called trades; they are sometimes called occupations.

Take, for example, the program to which one speaker referred this morning, that is put on in the Canal Zone. I happen to have been called down there 4 years ago to make a survey and to recommend a program. There we recommended apprenticeship for those occupations that have heretofore been common to apprenticeship, such as machinist, carpenter, and patternmaker, but we also extended the same principles, only under the title of "learnership," to those occupations in the commissary that are commonly known as salesman, buyers, stockmen, and so forth, where a considerable knowledge, technical knowledge, perhaps, and a certain amount of skill is necessary.

Dr. KREPS. Did you establish those in schools, or in the industrial plants?

Dr. WRIGHT. In the Canal Zone the industry is conducted entirely by the United States Government. The commissaries are operated by the Government. The largest maintenance-repair plant is operated

by the Government, but on a basis about the same as it would be if it were private industry.

Dr. KREPS. Then, returning to the mainland, would you establish schools in industrial plants in various industrial centers, or would you establish—

Dr. WRIGHT (interposing). The plan that is carried on in the Canal Zone provides that the apprentices are put to work by industry, but the school gives the related instruction. In that particular instance all the apprentices and learners were to be graduates of the high school, and the related instruction was carried on in connection with what they called their junior college.

Dr. KREPS. This would not be a substitute at all for the small-industry training programs that are necessary to train a semiskilled worker in 30 days or 60 days?

Dr. WRIGHT. No, sir. It is generally recognized that occupations which can be learned in a matter of months are hardly apprenticeable. Perhaps 1 or 2 years' length is about the minimum for which apprentices should be taken on.

Dr. ANDERSON. Dr. Wright, in an apprentice course of this kind, are you confining your effort only to those occupations which require that long a period of time, or have you devised ways of making a vocational training effective even for those persons who are going into a variety of semiskilled occupations?

Dr. WRIGHT. The present program as operated by the Federal Committee on Apprenticeship is one calling for, I believe, the minimum of 2,000 hours. That effectually sets up about a 2-year program. I do not believe that a formal apprenticeship ought to be set up for occupations which require only a few months for training.

Dr. ANDERSON. Mr. Green said something about the traditional set-up in the A. F. of L. which provided a certain number of apprentices per master. Is it true, as we heard, that the apprenticeship system is being broken down, and that some public agency such as the school must take over the training of masters?

Dr. WRIGHT. Apprenticeship as it existed 100 years or even 50 years ago has almost disappeared. At that time the apprentice was indentured to a master workman. The master had time while working to stop and instruct the apprentice. He was oftentimes responsible for the apprentice in the matters of education, matters of almost loco parentis.

Today master workmen do not have time to stop and instruct an apprentice. Modern methods of production call for high speed. Therefore, we have had to develop a new type of apprenticeship, one where the related instruction that the old master used to give on the job is now taught in the school, and where the apprentice gets his training on the job.

Dr. ANDERSON. In certain localities where I have noticed vocational training in progress, I have found some resentment on the part of craftsmen—for example, among electrical or other building tradesmen—against the schools entering this field. Is that characteristic or exceptional?

Dr. WRIGHT. Labor has consistently objected to any attempt to train more people for an occupation than there were opportunities for employment. In other words, I imagine, and I myself would agree with this statement, I think labor would—and I differ with one of the

speakers this morning—that the training should precede the opportunity for work. I think that it should be fairly well known that there is an opportunity for employment and that there are jobs before we set up a training program, and that there should be some definite relationship between the number trained and the opportunities for work. That enables us to make the training more specific.

Dr. KREPS. Would you care to elaborate on that just a moment—

Dr. WRIGHT (interposing). If you will permit me, just a moment—

Dr. KREPS. Because opportunities for work are obviously not a fixed quantity.

Dr. WRIGHT. If you will excuse me, I should like to finish my answer to his question.

The manner in which the relation between opportunities for work and the training provided are brought into balance is through the use of advisory committees, joint advisory committees, representative committees made up of labor, employers, and representatives of the schools. These committees are for the most part local, although there are State and national committees that advise in a general way. During this past year there were 1,343 of these committees in active operation.

These committees settle such questions. In addition, there are committees that are locally responsible for the indentureship of these apprentices under the Federal Committee on Apprenticeships Plan.

Dr. KREPS. Economic opportunities in any occupation cannot be forecast at a given time with any great degree of accuracy. You can never say that the opportunities now existing are the only ones that will exist in the future. Moreover, the number of opportunities that exist depends upon the price. It is quite conceivable that if you have increased the number in any skilled craft a great deal, that service will be available at a lower price. The demand for such services would be considerably expanded, for construction workers, or machinists you mentioned. Isn't it conceivable that a large increase in the number of machinists might decrease their hourly wage, but increase their annual income, and particularly the opportunities for machinists? Therefore, when you say we won't train people until we see opportunities, you have the cart before the horse.

Dr. ANDERSON. Let me add this one point because Dr. Kreps wasn't here this morning. That was precisely the thesis that Dr. Clark advanced this morning and caused considerable stir in the committee. When you said that you had some difference of opinion, it was on that very point, was it not, Mr. Wright? Apparently there are two very definite schools of thought on this subject, one that workers shouldn't be trained for jobs that are not available, the other that the field should be looked over to find the places where occupational returns are high. Therefore, since these are scarcity fields, new workers are shoved into them because the returns there are disproportionately high.

Mr. PIKE. May I make one observation at that point? During the lunch hour I was reading the proceedings of the New England Council last week in New Haven, and the head of one manufacturing company making, incidentally, precision tools, in talking to other manufacturers, said that he had been forced by the lack of fully trained mechanics, machinists, and inferred that it was due perhaps to the apprentice policy of only training men when there were jobs available, restrict, as it came to be, over a period of years by the

natural eagerness of that particular labor group to protect itself so that it dried up the supply, so when extra orders came he could not get trained mechanics, and he stated very flatly that now he was making better tools than ever without the trained mechanic or machinist in the old sense in his factory. He didn't have enough employment of that sort left to keep one trained toolmaker in his shop, he sent that work out. A few years ago he wouldn't have thought of putting anybody but a trained machinist or mechanic, a highly skilled workman, on any precision job in the shop. Now he is through with them and he doesn't need them any more.

That struck me, coming right after Dr. Clark had spoken, as being sort of first-hand evidence on the point favoring him.

During this particular meeting several other people in the same line of manufacture gave similar stories, that due to the lack of skilled people available they had split their work up in such a way that the average training period now necessary was not over 200 to 250 hours before a man could do any job in the shop, but he was in no sense a skilled man except on that particular thing. I thought it was evidence bearing directly on that point.

Dr. ANDERSON. This is perhaps the most crucial and controversial aspect of the topic of vocational training and placement. Because you are the head of a large enterprise that develops practical policies for the expenditure of Federal and other funds, we should like to have your opinion in the matter.

Dr. WRIGHT. Mr. Chairman, I am an administrator, I am not an economist, and therefore perhaps I should not take issue with those who are experts in that line. I differ with the statement to which you refer, if I correctly understood the speaker, that he would train people for jobs at the top without regard to the number of jobs that would be available, if that be a fairly correct statement of the problem. My reasons for differing with him are these: That vocational education at the best is more expensive than other forms of education, because unless the pupil has selected an occupation for which he wishes to be trained within reasonable limits I know of no way by which we can organize the instruction so that it will function in his occupation, in his future, as vocational training. Furthermore, unless we have a teacher who is occupationally competent, a master of the trade, and who has in addition been trained to teach, we have a very inefficient set-up.

OCCUPATIONAL TRAINING IN PUBLIC SCHOOLS

Dr. WRIGHT. We have throughout the country, as you all know, schools in manual training, industrial arts, industrial education. They are very essential parts of our public-school system, but they are not vocational. They may have in the shop the identical tools in the way of lathe equipment, machine-tool equipment, which would be used by another teacher with another group of pupils to teach the machinist trade, but the subject matter will be entirely different in many respects, the time given to it will be different, and the objective or the purpose for which the pupil takes it is different. It seldom inducts a boy into the occupation. I think it is a waste of the public's money, I think it is a waste of the pupil's time, and otherwise undesir-

able economically to attempt to train too many people for the higher jobs, and then let them percolate below.

My own view is that we need to select certain unit trades for what we call the day school, trades that can be analyzed to determine what subject matter should be taught, for which we can find a competent occupational teacher, and put him in charge of pupils who have been properly advised in the way of a guidance-testing program, and who of their own volition have chosen this occupation and want training in it. We should then give them the best training we can.

The best training that we can give under those conditions never takes place out of an apprenticeship, because it is impossible to duplicate in the schoolroom the conditions under which an apprentice has to work on the job. The matter of human relations, work with fellow men, spoilage of material, the calling down that he gets from the boss, and whatnot, are conditions that are foreign to the classroom, and we can't give him enough productive work, enough training for speed, to keep up with his fellow men as a journeyman. We in the vocational field admit and agree and believe that for the youngster in the secondary school the vocational school is never a supplement for full apprenticeship, but it is a school that advances him on his apprenticeship and makes him employable.

Then before leaving the top they must come to the other type of school. There were a little more than 2,000,000 enrolled in all the vocational schools during the last fiscal year under what we call the Federal-aid program. Of the 2,000,000, something over 1,100,000, or considerably more than 50 percent, are enrolled in the evening and part-time schools. They are not the youngsters who haven't yet got a job; they have a job; some of them may be temporarily out of a job due to these changing conditions, but they are workers and they are coming back to the school in the evening or in the daytime, even as a part of their working time, to secure a training and education which will enable them to progress and get ahead on their job.

I believe that that program which is for the employed people is of much greater importance vocationally than the other one, because they already have a job, it isn't a question of employment, but it is a question of giving them help which will enable them to keep their job or to get a better job. Have I answered your question?

Dr. KREPS. Let me see if I accurately get the picture you are trying to draw. I take it that you feel that the group at the top, the managerial group, cannot be trained?

Dr. WRIGHT. What do you mean by the managerial group?

Dr. KREPS. That group which you find in any large corporation which we call the executive group.

Dr. WRIGHT. Yes; I do believe that they can be given training. As a matter of fact, 20 years ago, or 19 years ago, I put on such a program myself at Big Stone Gap, Va., for the Stonega Coke & Coal Co. In one group which I had for 3 weeks for 3 hours a day were the general manager, his engineers, and some of his superintendents, 11 of them. In the afternoon for 3½ hours for 3 weeks I had a group of foremen, but I was not giving them training in the job of mining coal. It was a conference on what we called foremanship, and the first group in the morning were merely brought together for the purpose of acquainting them with the program that was being put on in the afternoon for their general foremen in the principles of managing men.

Dr. KREPS. If I understand you correctly, then, they could be trained in special schools in industry or special graduate schools of instruction or—

Dr. WRIGHT (interposing). It is on-the-job training, or training given in connection with their employment.

Dr. KREPS. You don't think we need to wait for an opportunity there. We can train as many as we like and hope we can reduce the compensation and get an increase in the supply of managerial talent in the country?

Dr. WRIGHT. With the exception of the engineers in this group, 3 or 4 engineers, the rest were all men who had been promoted to positions of superintendent from the ranks. I learned last Saturday night when I went down to their graduating exercises that one of the men who drove me from one camp to another who was a mine foreman, is now the superintendent in a large colliery. Another is general manager.

Dr. KREPS. Let me ask you another question. As I get it, the group at the bottom, the common laborer, semiskilled laborer, labor that can learn its occupation in 15 to 30 days, have nothing to gain from vocational education.

Dr. WRIGHT. Not in the field of coal mining. Using this same illustration, there are in that series, in that region of 5 counties in the western part of Virginia, about 1,500 to 2,000 miners attending evening classes each year. Last Saturday night I addressed 152 of them who had for 2 years taken a program of instruction sponsored by the State, in coal-mine timbering, in mine gases, in ventilation; there were 15 unit subjects dealing with underground work in the coal mine. They had successfully passed a stiff examination and were awarded diplomas. They had taken this because the State of Virginia requires that officials in the coal mine, beginning next July, must have a license.

Dr. KREPS. Does it extend beyond coal mining to a substantial range of manufacturing enterprise, or would you say the coal-mining example was somewhat exceptional?

Dr. WRIGHT. The same principle does not extend on a State-wide basis, so far as I know, to other fields. It does extend to various occupations in the city governments, such as inspectors of plumbing and electric wiring and other things of that sort. They must be licensed, too, if that is what you mean.

Dr. KREPS. Then what percentage would you estimate of the labor force can profit from an apprenticeship program?

Dr. WRIGHT. That is a very difficult question to answer. I know of no basis on which to set a percentage. I think it perhaps would always be a small part of the entire group, perhaps not more than 10 percent, but that is a guess.

TRAINING OF THE UNEMPLOYED

Dr. KREPS. Could vocational training be used as a way of helping people who were displaced to find another job in which they might utilize their capacities?

Dr. WRIGHT. Vocational training and education does not create work; it creates an ability on the part of human beings to do work.

Dr. KREPS. Do you think it should be used to educate persons who have been displaced who are still educable?

Dr. WRIGHT. I do, by all means. There are a considerable number of programs that have been organized in the past 6 or 7 years throughout the country for those whose jobs had to be changed. For example, when the Pennsylvania Railroad changed from steam engines to electric engines, a training program was put on in the State of New York in advance to give the training to steam engineers and firemen they would need to operate the electrically driven engines. Other illustrations could be cited in the same way. Where it is known that jobs are changing due to the introduction of new equipment or new methods, schools should be available for the purpose of giving the necessary training. I will give one more illustration. About 3 years ago, maybe 4, it was known in Portland, Oreg., that several large buildings were to be erected under specifications where the plumbing work would be welded instead of by the old screw method. The plumbers in the city, a union organization, held a meeting and took cognizance of the fact, and somebody proposed that they get back of a plan to be trained to weld by this new method.

They came to the Board of Education, and a plan was put up, teachers were secured, and 300 plumbers in that city within 6 or 12 months were given training in the field of gas welding or electric welding, whichever method was used, as a part of the tool of the plumber. Welding is not a trade; it is a tool in many trades. That is a pretty good illustration of these changing conditions and the extent to which vocational education can serve to keep them employable. As a result, instead of importing plumbers who could weld into Portland, when the buildings were erected the plumbing work was done by local plumbers.

Mr. PIKE. You made a pretty strong statement, Mr. Wright, which I can't find myself in total agreement with, that education cannot create work. I think Dr. Clark made a pretty good showing this morning on the other side, and I should more properly have asked the question from him, but I think you have had experience enough to answer this one that is in my mind. Suppose the opening toward all sorts of education were as free as he recommended. Wouldn't you have the same situation we always had in school, that a great majority of the boys showed a vast and consuming lack of interest in further education, beginning with the first or second grade? I remember quite a few that had to be whipped to school at eight, and as soon as they got too old to be whipped, quite a few of the boys quit. I am wondering what proportion in your work, say at Stonega, of the people who were entitled to take training were actually willing to take it and go through with it.

Dr. WRIGHT. I couldn't answer that question except to say that they had about 8,000 or 10,000 employees in their 10 different collieries. The largest group enrolled in any evening school year that I know of was 3,000.

Mr. PIKE. That would be the total enrollment, not stating whether they finished their courses.

Dr. WRIGHT. I couldn't say as to that.

Mr. PIKE. One could perhaps use the illustration of correspondence schools, where, even though at the learner's expense he has bought the course, yet in some cases he doesn't go on and finish it, even though it may be a good course. That was a thing that worried me when Dr. Clark was on the stand.

Dr. WRIGHT. If you will pardon me, I would like to use a chart I have back here to further answer your question.

On the morning of last June 2 I arrived in Buffalo at 7 in the morning. I was met at the station by the principal of the Burgard Vocational High School.

Dr. ANDERSON. That photograph will be admitted in the record.

(The photograph referred to was marked "Exhibit No. 2722" and appears facing p. 17158.)

Dr. WRIGHT. He said, "Before you go to your hotel I should like you to come over to our school, because I have something there to show you."

I went with him to the school, and here was a line of boys from the front door of the building extending back for seven blocks. These boys were graduates of the elementary schools and some 1 or 2 years in high school, and they had come on that morning to enroll in this school for the coming September, that particular morning having been set aside by the schools for enrollment in the seven vocational high schools in Buffalo for the coming September.

There was a total of 1,100 boys who came there that morning to enroll. Only 400 of them could be admitted. Of the 1,100, 700 wanted to take aviation, and the school maintains a department in aviation training giving an enrollment of a total of 400. That department of aviation admits 100 boys each year, and I said to the principal, "Well, if you are maintaining a total enrollment of 400, then it would seem to me that you would need to admit more than 100 freshmen, running the 4-year course."

He said, "No; we have practically no drop-outs. Ninety-seven percent of the boys who enter into this course finish."

I said, "What becomes of those 97 percent?"

He showed me the records extending back over, I think, about 10 years, which are kept for a period of 5 years for each boy after graduation, and I found that 90 percent, as I recall, of the boys who had entered into the aviation employment were still engaged in that particular field. I point this out merely as an answer to your question to this extent, that these boys, the 700 who came there, especially the 100 who were chosen, had very definitely made up their minds as to what they wanted to do.

In December of last year, the Board of Education announced that on the evening of January 2 they would open their evening schools in Buffalo, which had been closed for the first half of the school year because of lack of money. That group of 1,380 men came at 8:15 in the evening to enroll in this school. Only 1,200 of them could be accommodated by the capacity of the school. Thereafter they had to open another school, beginning about 4 o'clock in the evening, to accommodate the others.

Practically all of those 1,380 men were employed in the automotive industries, in repair stations, garages, filling stations; a large number of them were employed in aircraft. As many as could wanted to get into the aircraft business. Why? For two reasons. Buffalo has 2 very good aircraft factories, and they have very good relations with those factories, the factories are prepared to take all of the men the school can turn out.

I think these two pictures are illustrative of your question because they point to this one thing that is essential to a successful vocational

EXHIBIT No. 2722

124491-41-pt. 80 (Face p. 17158)

EXHIBIT No. 2723

124401—41—pt. 30 (Face p. 17150)

program, and that is that the youth or the adult must know very definitely what it is he wants to be trained for. When the school gives that training, you do not have these drop-outs that are so prevalent in other situations. I think that the drop-outs we have in our colleges due to failures and for other reasons would be materially reduced if the pupils went to college and paid their own way, rather than because it is the fashion, or because they are sent by their parents.

Dr. ANDERSON. Those people I presume in substantial number are unemployed?

Dr. WRIGHT. Quite a few of them, I wouldn't say a majority of them.

Dr. ANDERSON. We know, don't we, that a very substantial proportion of the youth population of 16 to 21 is unemployed and out of school.

Dr. WRIGHT. The average age is 23 of these in this evening school.

ADEQUACY OF PRESENT TRAINING PROGRAM

Dr. ANDERSON. Knowing the facilities available for vocational education so well, what in your opinion is the adequacy of the program? Is it meeting the need of all who desire it throughout the country? What proportion are not accommodated as a result of either lack of funds or other reasons that you might care to indicate?

The picture "Burgard Vocational High School, Buffalo" is submitted for the record.

(The photograph referred to was marked "Exhibit No. 2723" and appears facing p. 17159.)

Dr. WRIGHT. Mr. Chairman, I would like your permission to answer the question with the chart on vocational agriculture.

Dr. ANDERSON. The chart you refer to is submitted for the record.

(The chart referred to was marked "Exhibit No. 2724" and appears on p. 17160.)

Dr. WRIGHT. We ought to give agriculture a little recognition in this part of the program. This chart shows that for the year 1936-37 there were 6,004 departments of vocational agriculture in the rural high schools of the country. That number increased the next year to 6,904. In the following year, for 1938-39, it increased to 7,598, and in the present fiscal year the number is 8,194, enrolling about 250,000 boys and a few girls in vocational agriculture. But there yet remain 6,023 rural high schools in which there are no departments of vocational agriculture. There are no opportunities for those boys who live in those particular areas where these 6,000 schools are located, something more than one-half, about 60 percent, of these opportunities.

Dr. ANDERSON. This next chart you have put up, "Vocational Agricultural Departments," is admitted as an exhibit.

(The chart referred to was marked "Exhibit No. 2725" and appears facing p. 17164.)

Dr. WRIGHT. The pins on the map which have been photographed in black represent these 8,000 different departments showing the distribution over the country and the opportunities for these young men in vocational agriculture.

EXHIBIT No. 2724

VOCATIONAL AGRICULTURE48 STATES

Here is another chart, "Enrollment in All Schools Operated Under State Plans," including federally aided and nonfederally aided.

(The chart referred to was marked "Exhibit 2726" and appears on p. 17161.)

Dr. WRIGHT. The upper line represents the total enrollment in all vocational schools, something over 2,000,000, for the fiscal year ending June 30, 1939, and the lower curves show the proportion of these that are in the part-time, evening, and all-day schools. Notice that the part-time fluctuates with conditions of employment. In 1929 it began to drop and began to rise later.

The green line represents the evening school and shows a fairly steady rate. Until the last few years there has been a decided upward trend.

I think you will find a little bit more specific information on your question in this chart, "Enrollment in Federally Aided Trades and Industrial Classes, by Years, 1918-39."

EXHIBIT No. 2726

DIAGRAM I.—Enrollment in Vocational Schools or Classes Operated Under State Plans, by Years, 1918-39

CONCENTRATION OF ECONOMIC POWER

EXHIBIT No. 2727

DIAGRAM V.—Enrollment in Federally Aided Trade and Industrial Classes, by Years, 1918-39

(The chart referred to was marked "Exhibit No. 2727" and appears on p. 17162.)

Dr. WRIGHT. Again the upper curve represents the total enrollment. Then we have what we call the general continuation part-time school, which is operated for that miscellaneous group of employed young people who are oftentimes employed in jobs for which no specific training can very well be set up—office, messengers, and clerical positions. The green curve is the evening school and the yellow is the all-day school and below, the part-time trade extension. It is significant that this enrollment in the trade industrial classes fluctuates with conditions of employment.

A number of years ago the Y. M. C. A. made a study of their enrollments in evening classes and the conditions of industrial activity. It was found that during periods of unemployment men did not come to their evening classes, but that during periods of industrial activity when jobs were more plentiful, they began to come with a lag of about 6 months, I believe, in their enrollment. So you see, beginning again in '29 and '30, the enrollment in this group dropped very rapidly and since then has been increasing, due, of course, to two things, increased Federal funds available, but more largely, I think, to the upward trend of the evening school.

Dr. ANDERSON. You would say, Dr. Wright, in conclusion on this matter of attendance, that both in agricultural and industrial classes in the country no such thing as a full complement has been reached of either students' enrollment or facilities available for their schooling.

Dr. WRIGHT. I think the present program of the all-day school is available to only about 5 percent of those who want it, slightly less than 200,000 in total number. That, of course, covers the enrollment of 2 years at least, in some cases 4, which would be only about 100,000 for any 1 given year. It is a little bit difficult to answer your question exactly, but it would be easily safe to say that the program that is offered here is not yet available to large numbers of our people.

Dr. ANDERSON. Is that because of the newness of the program? I see the period goes all the way back to 1918, which would indicate that it is not a broad, new program. What is the cause of this tardiness in meeting the needs of our people?

Dr. WRIGHT. Largely a matter of funds and facilities in the way of buildings and equipment. Many of the public schools are just now beginning to awake to the need for providing buildings and equipment. I think it is due more, though, to the realization of the need of providing this type of training. When I was a member of the high-school faculties, previous to going into this program, I was earnestly working to get more and more pupils into this school. That was 30 years ago. Now two-thirds of all of our pupils of high-school age are in high school, 67 percent, and we don't know exactly what to do with them. There is a strong tendency on the part of school administrators today to turn toward vocational education as a solution of some of these difficulties. For my part, I again feel that the program of vocational education should not be introduced into the schools unless the school is prepared to maintain certain standards of instruction, qualifications of teachers, equipment, and buildings that will guarantee their ability to really give the student an employable asset.

Dr. ANDERSON. Is it fair to say that there is no oversupply of qualified teachers in this field of vocational education?

Dr. WRIGHT. No; there is an undersupply. The teachers in trades and industrial subjects must be secured from the trades, and today we are having difficulty in getting teachers from the trades who are not rather old.

Dr. ANDERSON. This would offer a fruitful field, then, for employment, would it not?

Dr. WRIGHT. As a teacher?

Dr. ANDERSON. Yes.

Dr. WRIGHT. Yes; but a teacher of a trade subject must first serve his apprenticeship or the equivalent of it, become a master workman, and, on the average, have experience of about 8 to 10 years as a journeyman before he is qualified to teach in the vocational school. Of course, we do have teachers of related subjects who do not go through that same experience. They perhaps have an engineering training and are qualified to teach the growing science of mathematics, English, and civics. But there would be, of course, to the extent that teachers are drawn from the trades, an opportunity for others in the trade to enter the trade to take the jobs that would be vacated.

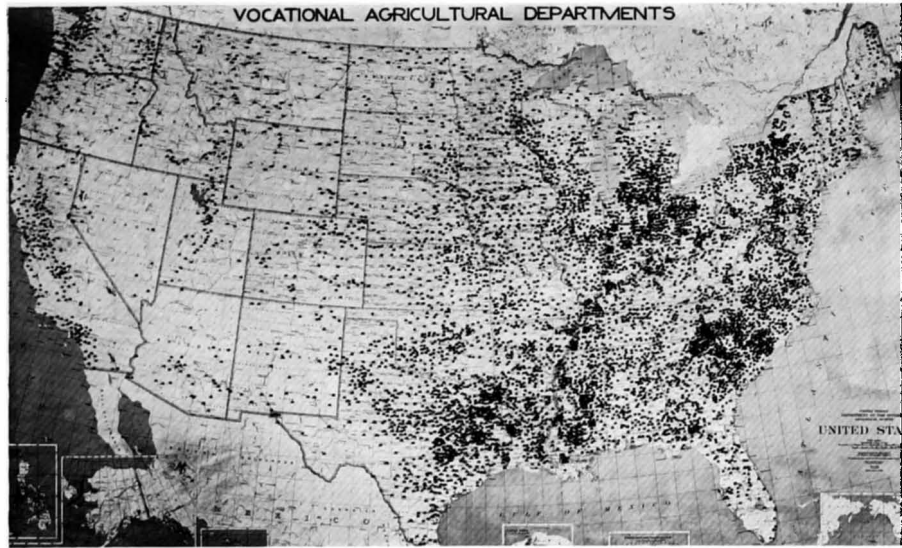

Dr. KREPS. Dr. Wright, I am impressed with the intensive character of the training that seems to characterize vocational-guidance programs. I may be wrong in this impression, but I wonder whether in addition to teaching them specific skills you teach them how to be a member of that trade. Do you teach them, for example, how to take their place with their fellow workers in a trade-union organization, how to read, interpret, and negotiate collective bargaining agreements; how to interpret the place of their vocation and their trade in the industry and in the business, and, furthermore, whether you go beyond teaching them to be industrial citizens, to be intelligent worker consumers, and teach them something about the market for their services. Is all that material extraneous to the courses and to the curriculum of vocational training as now given? Is it limited pretty specifically to development of particular skills which some new set of machines may make obsolete as opposed to giving them what I would call a training as a member of a vocation which might stand them in good stead no matter what particular machines were utilized?

Dr. WRIGHT. Well, I am not sure that I can remember all of the questions you have asked me, but I will try.

Dr. KREPS. There are two parts to it. One, do you teach them to be industrial citizens?

Dr. WRIGHT. We do not do very much, and it is a question that has not yet been answered as to how much we ought to try to do with the young people that are, let us say, 16, 17, or 18 years of age, in the way of teaching them the matters of labor organization, collective bargaining, and other matters that sometimes get into controversial fields. To the extent that a teacher who has been employed, and a great many of them are, is a member of a union organization, there is no objection on the part of the school to his explaining such matters as a part of his trade instruction, but there have been several examples in the last several years, and going on now in California, where classes of older workers and business agents, even, are brought together under a teacher of their own choosing, or a conference leader, to discuss mat-

Exhibit No. 2725

124401—41—pt. 30 (Face p. 17164)

ters in collective bargaining and organization, and so forth. For my own part I think it is a safe matter to include in the adult program, but there is still a question as to the advisability of putting it into the secondary program.

EFFICACY OF VOCATIONAL GUIDANCE

Dr. ANDERSON. Dr. Wright, there is a problem that has always bothered me as a person who has had some background in the field of education and in fairly close relationship to the field that you have been discussing. It seems implied in any program of vocational education that an effective vocational-guidance program will either accompany it or precede it or in some way be associated with it. You are very familiar undoubtedly with the vocational-guidance programs the country over. What would your judgment be as to their effectiveness in actually getting at the material that is basic information for youth, for those to be guided, and in making that material effective in the guidance of youth into occupational life?

Dr. WRIGHT. I think the first responsibility that the schools have in that field of occupational information and guidance is one of occupational information. I think that information ought to be given to our pupils in the secondary schools in an entirely unbiased way so that the pupil would not be unduly directed toward one field or one occupation over another. At least, he ought not to be taught that it was degrading to be employed in any one field of honest endeavor. The second thing is that we need to get a great deal of information about our pupils.

That information should be secured throughout a rather long period of years, beginning fairly early, and made accumulative through pupil record cards, so that at the time when the pupil thinks that he needs advice about occupation, whether he should go to a vocational school or college or what he should do, the counselor then would have before him a fairly good history of the pupil for a considerable period of years. It is needless to say that this counselor is serving or should serve in the position of the parent, as the parent used to do, but which parents have now fallen down on in that they are so remote from many of these activities, and do not counsel their own children. He should give this advice to a pupil or pupil and parent in a factual way and without bias, and leave it to the pupil and parent to make their own selection as to the field of training in which the pupil wants to enter. If that field calls for high-school graduation and college, then that is the activity which they ought to advise them in. If on the other hand it does not, and the economic situation of the family calls for earlier wage earning or there is lack of funds to attend college, perhaps the youth will elect to enroll in the vocational school and get into productive work at an earlier age.

Dr. ANDERSON. Dr. Wright, what is your opinion of the effectiveness of the programs you have seen the country over.

Dr. WRIGHT. I think it is fairly effective, because we don't have a large turn-over in our vocational schools such as we had 20 years ago.

Dr. ANDERSON. Do you attribute that to the greater effectiveness of the guidance aspect of the program?

Dr. WRIGHT. Yes, sir. There are about three fundamental characteristics of an efficient teaching situation, as I see it. The first one is that your pupils should be properly selected on the basis that they are prepared to receive the instruction and will use it after they have received it. The second one is that your teachers should be occupationally competent and trained to teach. The third is that the subject matter that is taught should be functioning in the occupation for which the pupil is being trained—

Dr. ANDERSON (interposing). There is only one other question that comes to me beyond this excellent summary you have given, and it is one that has caused some doubt in the minds of people out West, at least, and I presume in other States. Is it your opinion that it is a function of the State to provide adult education at public expense of a specific training character as well as other kinds of adult education?

Dr. WRIGHT. Absolutely. I believe that we are at the point in America where all education for youth up to a certain year—perhaps 16, perhaps 18—should be regarded as a public responsibility to provide an opportunity. I think that we also are in this country at the point where we recognize that we owe to the adult a similar opportunity to come to an evening school and secure his training at public expense.

Dr. ANDERSON. Do you think that is both a socially desirable and economically sound policy?

Dr. WRIGHT. I do.

Acting Chairman O'CONNELL. Mr. Wright, it is now beyond the time we usually adjourn. Have you anything in particular you would like to emphasize in the statement?

Dr. WRIGHT. I do have, sir, just one, which will take just a moment. I brought with me a few publications. Here is one entitled "Training for the Painting and Decorating Trade." It illustrates the procedure that we use in developing subject matter through the assistance of journeymen workers in the trade. And on pages 5 and 6 of this publication we have some data that, with your permission, I would like to suggest be included in the record. And diagram I on the subsequent page discloses a most interesting story about that fact that today many of our highly skilled occupations are becoming old men's trades. The average age I think in this particular case is something like 55.

Acting Chairman O'CONNELL. In what trade is that?

Dr. WRIGHT. Painting and decorating. Whatever the figure is, these six points that accompany the chart will disclose the point I want to make, unless you wish to give me time to review them.

About 62½ percent of the persons employed are from 25 to 40 years of age, and I think the statement is made that there are more men over 60 in that occupation that are working than there are under 25 years of age. I reserve the right to correct these figures, but it clearly shows the fact that in that particular trade according to the United States census, it is becoming an old man's occupation. The gravity of the situation is that the number of apprentices that are in training are entirely inadequate to take the place of those who will be passing out. I have about five of these if you want them.

Acting Chairman O'CONNELL. They may be left with Dr. Anderson as a file exhibit.

(The document referred to was marked "Exhibit No. 2728" and is on file with the committee.)

Dr. ANDERSON. Before we adjourn, in order to clean up the business of the day, there are several—

Dr. WRIGHT (interposing). May I make one more statement? I sent over to my office as a result of an arrangement made this morning for a little publication called "Automobile Facts and Figures." It was issued by the Automobile Manufacturers Association. I am not prepared to say how accurate these figures are that come from it, but you will know as much as I do about it.

On page 47 I find a statement of numbers that are employed.

Mr. KREPS. Is that number employed or number representing themselves as having an occupation in the automobile industry?

Dr. WRIGHT. The heading says, "Millions Employed in Motor Transportation," and so forth.

Mr. KREPS. Is that a census of employment?

Acting Chairman O'CONNELL. Dr. Wright doesn't know, but we will accept the figures.

Dr. WRIGHT. The question of whether it is the full number or not is immaterial to the point that I want to make. There are about 6 columns in this table. The first column shows that there are 713,611 employed in the manufacturing end of that business out of the 6,000,000. The next column shows a little over 1,000,000 employed in sales servicing, and then there are 267,000 Federal and State road building, and then we come to an item of 3,544,956 that are said to be employed as truck drivers with an additional 177,000 as bus drivers and those are the 2 figures that I want to talk to, because they represent more than 50 percent of this number that are represented as being employed, and the statement was made this morning, or inferred, that many of our new industries that grow up do not provide new jobs for which training is needed, that things were handled by automatic machinery, and so forth. In this industry if there be over 6,000,000 employed and if there be over 50 percent of them employed as truck drivers and bus drivers, they alone call for a training program. They are operating equipment over our roads. You go touring, as I did 2 weeks ago to Florida, and you will meet many of them; they are traveling at 50 and 60 miles an hour.

You will meet on a trip of that kind a half dozen situations where the driver and his assistant and maybe the second car will be stopped and they will be down under fixing some part of the apparatus or the engine is out of repair or something needs to be done to it to keep it rolling. There is too much equipment, too much investment, for those men to be put in charge of those jobs who do not know how to make repairs and keep them going. I happen to have specialized some in that field some years ago, I am the author of four books on that subject, and I know that those men have to be trained in some way. It is not a common labor job. While you are sitting up there at the wheel steering along, that seems very simple, but when something goes wrong, if it is only once on a half-dozen trips, the man must be just as well prepared as though it happened every hour.

17168

CONCENTRATION OF ECONOMIC POWER

Thank you.

Acting Chairman O'CONNELL. Thank you very much, Mr. Wright.

Dr. ANDERSON. Mr. Chairman, we have several additional exhibits for insertion in the record.

Acting Chairman O'CONNELL. They will all be admitted.

(The documents referred to were marked "Exhibits Nos. 2729 to 2734" and are included in the appendix on pp. 17493-17503.)

Acting Chairman O'CONNELL. The committee will stand in recess until 10 o'clock.

(Whereupon, at 5:25 p. m., a recess was taken until 10 a. m., Friday, April 26.)

INVESTIGATION OF CONCENTRATION OF ECONOMIC POWER

FRIDAY, APRIL 26, 1940

UNITED STATES SENATE,
TEMPORARY NATIONAL ECONOMIC COMMITTEE.
Washington, D. C.

The committee met at 10 a. m., pursuant to adjournment on Thursday, April 25, 1940, in the Caucus Room, Senate Office Building, Mr. Joseph J. O'Connell, Jr., special assistant to the general counsel, Treasury Department, presiding.

Present: Mr. O'Connell (acting chairman); Senators O'Mahoney (chairman) and King; Representatives Williams; Messrs. Kades, Pike, Lubin, Hinrichs, Kreps, and Brackett.

Present also: S. Abbot Maginnis, Department of Justice; William T. Chantland, Federal Trade Commission; and Dewey Anderson, economic consultant to the committee.

Acting Chairman O'CONNELL. The committee will be in order.

Dr. ANDERSON. Mr. Chairman, we agreed to come here at 10 o'clock this morning in order to make an attempt to wind up the 3 weeks' hearings during the day. The schedule is very heavy. We have three witnesses this morning. The first witness is Dr. William G. Carr, executive secretary of the Educational Policies Commission and director of research of the National Education Association, who will make the summary statement concerning education and its relationship to the problem of technology that the committee has been discussing.

Dr. Carr is before you and ready to be sworn.

Acting Chairman O'CONNELL. Do you swear that the testimony you are about to give in this proceeding shall be the truth, the whole truth, and nothing but the truth, so help you God?

Dr. CARR. I do.

TESTIMONY OF DR. WILLIAM G. CARR, SECRETARY, EDUCATIONAL POLICIES COMMISSION, WASHINGTON, D. C.

Dr. ANDERSON. Dr. Carr, what is your position in the Educational Policies Commission?

Dr. CARR. I am secretary of the Educational Policies Commission.

Dr. ANDERSON. What is the commission itself?

Dr. CARR. It is an organization of 20 people, created by the National Education Association to develop American educational policy in this critical period.

Dr. ANDERSON. What is the National Education Association?

Dr. CARR. It is a professional organization of workers in education.

Dr. ANDERSON. How many members does it have?

Dr. CARR. Roughly, 200,000.

Dr. ANDERSON. Is it the principal organization in the United States affecting workers in education?

Dr. CARR. Yes. It enrolls more than any other national organization.

Dr. ANDERSON. And your position is what?

Dr. CARR. I am the secretary of the Educational Policies Commission, and director of research for the association.

Dr. ANDERSON. You have worked in the field under review, that of training citizens to meet the problems of the present-day economy?

Dr. CARR. Yes, sir.

Dr. ANDERSON. You have published in that field?

Dr. CARR. Yes, sir. The Educational Policies Commission has a volume on the purposes of education in American democracy, which they asked me to draft. It is part of a series that Dr. Norton referred to yesterday.

Dr. ANDERSON. And beyond that, have you written in the field of citizenship and the training of citizens?

Dr. CARR. We have just finished a Nation-wide study of the work of American high schools in training for economic citizenship. In the course of this study we have visited 90 schools in 27 States. We have interviewed many thousands of teachers, laymen, members of boards of education, labor leaders, editors, and the like, and have observed over 2,000 classroom teachers of superior quality in their classrooms at work making American citizens.

Dr. ANDERSON. And that work was under your direction?

Dr. CARR. It was.

Dr. ANDERSON. Some time earlier did you not publish a book in the field of citizenship and citizenship training?

Dr. CARR. A long time ago; not recently.

Dr. ANDERSON. All right, Dr. Carr, if you will proceed.

Dr. CARR. Mr. Chairman, knowing the limitations of time on your committee, I shall not, if I may, read the entire statement that I prepared, but simply ask that it be incorporated in the record. I am referring to the one headed "Education and economic literacy."

Acting Chairman O'CONNELL. The statement will be incorporated in the record as it has been prepared.

Dr. CARR. The staff of the Educational Policies Commission has just completed a study of the pioneering aspects of citizenship education in American secondary schools. My comments will be based in part on the observations of our staff in connection with this investigation, and in part on the Commission's publications on Education and Economic Well-Being in American Democracy¹ and The Purposes of Education in American Democracy.²

The civic education study involved first-hand observation of the work of 90 first-class American secondary schools of various types. The schools were located in 27 different States and were scattered in many kinds of communities throughout the country. The field work involved conferences with school officials, school-board members, teachers, students, and interested members of the public; the

² National Education Association and American Association of School Administrators, Educational Policies Commission. The Purposes of Education in American Democracy. Washington, D. C.: The Commission, 1938.

examination of school records, courses of study, and other printed materials; and the observation of the work of approximately 2,000 classroom teachers who are doing outstanding work in the development of intelligent citizenship.

NEED FOR ECONOMIC LITERACY

Dr. CARR. As long as we aspire to operate our common affairs through representative and democratic procedures, we shall need economic intelligence on the part of the masses of the people. Problems of citizenship and government are today closely related to problems of economic adjustment. In advanced industrial countries it is probable that the level of economic welfare is depressed as much by the lack of economic intelligence and social cooperation among the masses of the people as it is by inability to produce and consume.

The people of the United States are called upon to make decisions with reference to a wide range of economic matters. It is true that, in some of the more technical aspects of these decisions, they may, and indeed should, utilize the judgment of qualified experts. But the definition of goals and, to a considerable degree, the choice of methods for reaching those goals will be controlled by the diffusion of knowledge and ideals, or by the lack of knowledge and ideals, among the people. An ability to deal with economic forces and facts in a realistic manner, plus a social idealism to direct the necessary adjustments to modern technological conditions, are proper and legitimate purposes of that system of universal education which is provided everywhere in the United States.

Many schools are already making deliberate efforts to render the entire population literate as far as economic problems are concerned. Verbal, or alphabetic literacy, has already been practically achieved. Illiteracy of this particular type has declined in the United States to the point at which the Census Bureau felt it unnecessary to include a literacy question in its 1940 enumeration. The Bureau has substituted in its place a question relating to the grade level of schooling attained. But, without appropriate educational methods, verbal literacy will not automatically extend to the mastery of other fields of knowledge.

One may be very modest in what he claims schooling can do to develop economic literacy, and still make a powerful case for dealing with economic facts and problems in the schools. Much of the urge toward dictatorship in the world today arises from the necessity of securing action on economic issues that are not sufficiently understood by the masses of the people. Ignorance is the great subverter of democracy because, in the presence of ignorance, necessary action can be taken only by deserting democratic principles.

It may be well at this point to emphasize a point which has already been stated by other witnesses. We do not provide universal education in this country solely because it may aid in increasing our economic welfare. There are many other excellent reasons for providing general education. Furthermore, it is entirely possible to think of a type of schooling that would not increase the economic welfare of society one bit. We could all study astrology for 20 years and still not materially increase our economic well-being. This, of course, is an extreme illustration, but it demonstrates a

source of real difficulty. If we wish schooling to improve economic welfare, it must be reasonably well adjusted to that end.

Economic literacy may be narrowly defined as such acquaintance with basic economic facts as will make it possible for citizens to comprehend the economic problems which confront them. More broadly conceived, the term covers attitudes and ideals as well as knowledge and skill in the economic sphere. Unless the average citizen is the final arbiter of economic issues, democracy is functioning poorly; and yet, unless the average citizens has some information upon which to base his judgment and some social philosophy within which it may be exercised, the resulting decisions are apt to be haphazard, inefficient, guided by prejudice, and of doubtful value to the general economic welfare.

Education affects economic well-being in two ways. First, and most easily, education can disseminate knowledge. The development of social statistics and the other social sciences in institutions of higher education and in governmental agencies is helping greatly to increase the range and specificity of our knowledge about social problems.

Second, education can help people to apply this knowledge wisely to human needs—individual and social. From this part of the educational process arises a public demand for remedial action directed toward unsatisfactory economic conditions. Without this public demand, political leadership will remain impotent, no matter how high-minded or well-equipped in the technical sense that leadership may be.

In order that he may deal wisely with the economic problems on which, through ballot and otherwise, he registers an opinion, the citizen must be acquainted with some of the basic economic facts and problems. He should be sensitized to the importance of these problems, to the difficulties involved in their solution, and to his own responsibility with relation to them. He should know the proposed remedies for economic difficulties and the advantages or dangers which these solutions may involve. He must know the reliable sources of economic information which he can use with confidence to supplement his own knowledge. Such a standard is beyond the present attainments of the average adult. It appears, however, entirely practicable to achieve such a standard through a well-conceived program of education. The relentless pressure of political and economic developments make such education more necessary with the passing of every hour.

ECONOMIC INFORMATION NEEDED

DR. CARR. Let us enumerate, by way of illustration, a few of the basic economic facts which every citizen ought to know and some of the outstanding economic problems with which he should be conversant. I attempt no complete or authoritative catalog; others are more competent than I to present such an analysis to this committee.

The blessings of this country in natural resources are well known to all students of economy. This knowledge should be extended to the entire population. The American people should know that their land is enormously wealthy in its natural resources, and that although the soil has been used with reckless abandon and its fertility depleted in many sections, it is still capable, by and large, of producing the necessities of the American people, as well as a part of the necessities of the rest of the world.

The citizen who is economically literate will also know in general about our network of transportation and communication. He will have a general understanding of the relation of the various means of transportation and communication to each other, to the public, and to the Government.

The educated citizen will know something about other aspects of the rich and varied capital resources of the Nation. He will know that by no means the least important of the great resources of the United States is the cultural and technical heritage which the people of the country possess; first, in recorded form, and, second, in the knowledge and skill of individual citizens. It would be impossible, of course, to estimate the monetary worth of the learning possessed by the Nation's scientists, its professional and business men, and its laboring classes, and of the general level of intellectual attainment throughout the country.

The educated citizen will have some information about the industrial organization of the United States. He will know about the growth of modern industry, the importance of machines, particularly power-driven machines, the specialization of labor, the demand for large markets, the credit basis of many transactions, and group action on the part of producers and workers. He will know about the status of various social reforms designed to ameliorate the impact of economic changes upon the individual, such as workmen's compensation laws, laws relating to public health, public housing, and social insurance of various types.

A mere knowledge of the facts alone is important, but it is not sufficient. Upon the measure of success which citizens achieve in identifying and solving the problems which grow out of these facts is dependent the future welfare of this country and its continued existence as a democracy. And the quality of national decisions on economic questions is conditioned partly by the intelligence and information of the voters and partly by their personal and social ideals.

Generally speaking, it has been our observation that the schools of America are doing a reasonably adequate job in transmitting to young people a factual knowledge along lines such as I have just outlined. There are, of course, many imperfections in connection with this task, imperfections which grow out of the limited ability of some students, and of some teachers. A much better job could be done, and no doubt will be done in the future, in the imparting of information. This, however, is probably one of the least of the problems facing American education with reference to economic literacy. Information by itself is relatively uninteresting and relatively low in social value. Unless related to some problem which is sensed by the learner, facts are learned with difficulty and forgotten with astonishing ease and rapidity.

The economic problems pressing upon the United States are, as this committee is well aware, highly complex in their relationship. For the purpose of discussing what the schools might do and are doing with reference to these problems, it may be convenient, although admittedly an oversimplification, to identify them in four groups: (1) Problems relating primarily to production; (2) problems relating primarily to consumption; (3) problems relating largely to governmental functions; and (4) the major problem which relates to the type of economic organization which will be most effective in serving

the economic welfare of the country and in conserving its political and social ideals. The fourth problem, of course, is basic to all the others.

To say that the United States is faced with economic difficulties does not necessarily imply that all of them must be solved by the Government. It does mean, however, that they must be met in some fashion by the citizens of this country either through Government or through business, social, and other nongovernmental groups. In either case an intelligent solution waits upon the considered action of intelligent individuals making up the electorate or comprising the business and social groups involved. Therefore, the more widely diffused is economic literacy, the more likely will be a happy solution of these critical economic difficulties.

Let me list a few of the problems which you would be likely to find under discussion if you would visit for a few days any one of hundreds of good American secondary schools.

1. Problems relating primarily to production.

a. The business cycle—its possible causes, its control, and the effects of periods of depression on human beings.

b. Industry—its historical background since the industrial revolution, the growth of large industrial enterprises, and the problems accompanying such growth, regulatory legislation.

c. Agriculture and its economic problems—farm debt, farm production, crop irregularities, price irregularities, and the measures taken to offset the disadvantages of agriculture.

d. The conservation of natural resources—the natural endowment of the United States, the use of that endowment, its exploitation, the possibilities of conservation and wise use in the future.

e. Transportation and communication problems—the historical development of various types of transportation and communication, the relation of Government to commerce and communication, Government subsidies, Government regulation versus Government ownership, freedom of speech as related to control of the media of communication, tax policies with reference to the communication and transportation industries.

f. Public utilities—their monopolistic nature, regulation, public ownership, other possible solutions.

g. Labor relations—the operation of trade unions and of employers' organizations, collective bargaining, wage rates and conditions of employment, legislation protecting labor, safety legislation, workmen's compensation laws, wages-and-hours legislation, the enforcement of labor laws.

2. Problems relating primarily to consumption:

a. How the national income is distributed.

b. Savings and other provisions for social security, including Government action.

c. The protection and education of the consumer in the fields of food, clothing, and housing particularly—the role of private enterprise and of Government regulations in protecting the consumer.

3. Problems relating primarily to governmental functions:

a. The control and issuance of money.

b. Public finance—taxation, the public debt, the distribution of public expenditures, the efficiency of public administration, the number

and size of tax-levying units, types of taxation, and the economic effects of tax levies.

c. The relation of Government to problems of production and consumption listed under 1 and 2, above.

4. The major problem relating to the type of economic organization to be chosen in this country—the nature and disadvantages of the various possible forms of economic organization—possible modifications in the present economic organization.

SUMMARY

Dr. CARR. Most of us look at our economic problems through a lens of exceedingly short focus. The members of this committee who hold their positions because of the votes of their fellow citizens in various parts of the United States would probably agree with me that it is by no means easy to persuade voters to look at national economic and political issues from a long-range, Nation-wide viewpoint. All of us tend very naturally to consider only our own immediate business and that of our friends and neighbors. It is probable that this tendency of human nature will persist. However, it is possible, through a properly devised program of education, to do several things about this difficulty. In the first place, education may make the citizen aware of conditions affecting his own personal welfare which, without the education, he would not recognize as being of any importance to him. He can be made aware of the distinction between a temporary change and a long-time trend. Furthermore, the possibility of broadening social viewpoints, of breaking down narrow provincialism, and of increasing an unselfish devotion to the common good through education, is by no means remote.

Government has always been closely related to economic problems. Whether or not that relationship is becoming closer with the passage of time, it is certainly true that the major problems of public life have important economic aspects. The issues upon which elections turn, the questions which agitate the public mind, the problems debated by legislative bodies, and the duties of public officials, are very frequently economic in nature or in origin. The citizen of a democracy, therefore, needs to acquire the information, the experience, and the willingness to deal constructively with collective economic problems. Each needs also information, experience, and motivation to maintain his own economic contribution at a high level.

The person who is economically literate has found out, by direct or vicarious experience, that goods and services usually vary greatly in quality; that advertising is interested in selling goods, services, or ideas; that collective expenditures, in cooperatives or in public finance, for example, may be either good or bad depending on the attendant circumstances; that getting something for nothing, through gambling in any of its forms, always means that the other fellow gets nothing for something; that every dollar spent is an economic ballot voting for necessities or for trash; that war uses natural resources to destroy human resources; and that individual economic advancement through deceit or exploitation of others is unworthy of an honest man.

The citizen who is economically literate is acquainted with certain broad economic issues, conditions, and procedures. He has become familiar through frequent usage with currently important economic

concepts, with the ideas of supply and demand, investment and profit, capital and labor, scarcity and abundance, monopoly, the market, wages, and prices. He is informed concerning the principal economic developments under public auspices, such as the Tennessee Valley power projects and the Social Security laws. He sees these trends and conditions in the light of their historic antecedents. He knows certain facts which are crucial to the economic life of the country—its basic physical and human resources, its potential and actual productivity, the distribution of incomes and wealth, and the degree of concentration or dispersal of ownership and management. Only as a growing degree of competence and interest in these matters is diffused among the people can democracy function in the teeth of technological change.

Should an investigating committee which is studying the economic effectiveness of this country be concerned with matters of education? The whole burden of my testimony, and that of the other witnesses, has been to the effect that education has highly important effects on the efficiency and equity of the economic system. In order to maximize these effects, certain types of legislation are required and certain public attitudes must be developed.

A school system which fails to reach a large proportion of the young people of secondary school age cannot make these particular young people economically literate. Hence, legislation which keeps youths in school and which provides schools for them to attend is legislation in the interest of economic well-being.

If the schools are so overcrowded and so meagerly financed that an adequate program can scarcely be offered, economic well-being is decreased. Consequently, State and Federal legislation which looks to the lessening of the inequalities of educational opportunity and the provision of adequate funds and personnel for education is in the interest of economic efficiency.

If public indifference or antagonism prevent realistic instruction in the current problems of citizenship and of economic adjustment, education for economic literacy is stymied and economic well-being is thereby depressed. Consequently, anything that can be done by way of legislation—Federal, State, or local—to protect the integrity of the educational system from those who would bar the discussion of economic issues or would limit discussion to a single prejudiced point of view is in the interest of education for economic literacy, and therefore in the interest of economic well-being for the people of the United States. What goes on in American schoolrooms with reference to economic teaching or what fails to go on in these schoolrooms will reappear in the economic life of the Nation within the next few decades, just as surely as the day follows the dawn.

I will comment on it very briefly, calling your attention, repeating, if I may, to one or two paragraphs which I think summarize the entire statement. The first paragraphs give a little of the nature of the evidence on which this report is based, largely in connection with the various publications of the Educational Policies Commission and in connection with this study of citizenship education which we are now engaged in writing and to which Dr. Anderson has referred.

The general nature of the problem is set out in the next paragraph. As long as we aspire to operate our common affairs through rep-

representative and democratic procedures, we shall need economic intelligence on the part of the masses of the people. Problems of citizenship and government are today closely related to problems of economic adjustment. In advanced industrial countries it is probable that the level of economic welfare is depressed as much by the lack of economic intelligence and social cooperation among the masses of the people as it is by inability to produce and consume.

Repeating again:

One may be very modest. I think one should be very modest, in what he claims schooling can do to develop economic literacy, and still with that modesty he can make a very powerful case for dealing with economic facts and problems in the schools. Much of the urge toward dictatorship in the world today arises from the necessity of securing action on economic issues that are not sufficiently understood by the masses of the people. Ignorance is the great subverter of democracy, because, in the presence of ignorance, necessary action can be taken only by deserting democratic principles.

(Senator King assumed the chair.)

Acting Chairman KING. Political ambitions in connection with economic questions impel many people to do so.

Dr. CARR. That is true as far as the ambitious politician is concerned, but since in a democracy he must in the last analysis secure his position through the suffrage of the people, I think you will feel that public ignorance is part of the problem.

In the presence of ignorance, necessary action with regard to crying economic and social needs cannot be taken by democratic means, and hence autocratic means are resorted to.

Just a word as to the definition of economic literacy which this paper supposes.

Economic literacy may be narrowly defined as such acquaintance with basic economic facts as will make it possible for citizens to comprehend the economic problems which confront them. More broadly conceived, the term covers attitudes and ideals as well as knowledge and skill in the economic sphere. Unless the average citizen is the final arbiter of economic issues, democracy is functioning poorly; and yet, unless the average citizen has some information upon which to base his judgment and some social philosophy within which it may be exercised, the resulting decisions are apt to be haphazard, inefficient, guided by prejudice, and of doubtful value to the general economic welfare.

DEMOCRACY DEPENDS UPON ECONOMIC KNOWLEDGE

Dr. CARR. I shall not take your time to develop any of the additional points. Knowledge of economic facts alone is important, but it is not sufficient for this country, or for any democracy. Upon the measure of success which citizens achieve in solving economic problems, which in part requires the acquisition of facts and in part assumes ideals and attitudes and social philosophies, our democracy depends.

The quality of national decisions on economic questions is conditioned partly by the intelligence and information of the voters and partly by their personal and social ideals.

I should like, therefore, to suggest that we think of economic literacy in that dual sense. It has been the observation of our staff in visiting these American schools that the secondary schools are doing a reasonably adequate job in transmitting to the younger

generation a basic factual knowledge with regard to many of our economic issues. There are, of course, many imperfections which arise from the ability or lack of ability of the students and of the teachers. No doubt a better job can be done and will be done in the future in this factual area. But this is probably one of the least important aspects in the development of economic literacy. Information by itself, as we all remember from our own school days, is relatively uninteresting unless it is related to some issues which the learner himself feels to be important. If it is not so related, the information is acquired with great pain, and forgotten with remarkable speed.

I should like to introduce, if I may, Mr. Chairman, into the record at this point some examples of how American schools are developing their instruction in these economic areas. In the testimony quoted above, I have outlined a series of economic problems which we find American schools are dealing with, and I have prepared here a statement headed "Examples of study units on economic problems from American secondary schools," which illustrate the approach that is being followed in American schools with reference to these problems. This printed material I am sure you will realize is a very poor substitute for the exciting experience of stepping into a classroom and seeing a teacher in action, but it is the best we can do for this committee, and I would like to introduce that information in the record.

Acting Chairman KING. It may be received.

(The document referred to was marked "Exhibit No. 2735" and is included in the appendix on p. 17054-17515.)

Acting Chairman KING. I would like to inquire if in statement you have just made you include only the public schools, or the universities and those so-called higher branches of education?

Dr. CARR. Our actual observations, Senator, are limited to secondary schools and junior colleges. I have reason to suppose that the same generalization would apply to the higher institutions. Perhaps, and this is just a guess, our higher institutions emphasize the factual side of economic literacy, even more to the exclusion of the idealistic and attitudinal side than the lower institutions do. I couldn't back that up with evidence; it is just a guess.

I should like to repeat the concluding three paragraphs of the testimony which I prepared for this committee:

Should an investigating committee which is studying the economic effectiveness of this country be concerned with matters of education? The whole burden of my testimony, and that of the other witnesses, has been to the effect that education has highly important effects on the efficiency and equity of the economic system. In order to maximize these effects, certain types of legislation are required and certain public attitudes must be developed.

I would like to interrupt my written testimony there to say that I do not by any means, nor do educators generally, assume that the solution of educational problems stems wholly from legislation by the Congress or by State legislators or city councils or boards of education; it stems in considerable part from the wisdom, the intelligence, and the devotion to the ideals which the schools represent, which the common people hold; but let us take some examples in the legislative area.

A school system which fails to reach a large proportion of the young people of secondary school age cannot make these particular young

people economically literate. They are not in the school. Hence, legislation which tends to keep youths in good schools and which provides schools for them to attend is legislation in the interest of economic well-being.

Again, if the schools are overcrowded, if they are so meagerly financed that you just can't offer an adequate program, economic well-being is indirectly decreased. Therefore, State and Federal legislation which looks to the lessening of the existing inequalities of educational opportunity and the provision of adequate funds and personnel for education is in the interest of economic efficiency.

I should like the members of this committee to have been with me time and again when we visited these American secondary schools. Almost without exception they all bulge. They are built for 1,500 students and they have 1,800, 2,000, 2,500, double shifts, no room in the cafeteria, no room on the playground. They are doing a splendid job against great handicaps, frequently understaffed, staff working from early morning until late at night to carry on the program, with no loss in efficiency. Now, anything which improves the effectiveness of the school itself, if you grant my primary assumption, will be in the interest of economic well-being for this country.

Again, if public indifference or antagonism prevents realistic, honest instruction in the current problems of citizenship and of economic well-being, education for economic literacy is stymied and education for economic well-being is thereby decreased in efficiency. And so anything that can be done by way of legislation or by way of modification of public opinion which will protect the integrity of the educational system from those who would bar the discussion of economic issues or who would limit the discussion of economic issues to a single prejudiced, partisan viewpoint is in the interest of economic literacy and hence, in the long run, in the interest of economic well-being in this country. What goes on in American schoolrooms with reference to economic teaching or civic teaching or the lack of it will be reflected in the economic well-being of this country in the next generation just as surely as the noon follows the dawn.

Now, Mr. Chairman, may I move over very rapidly to an attempt, hastily conceived, to summarize the testimony of the other members of the panel with reference to education? I would like to suggest that there be distributed to the members of the Committee the statement headed, "Summary of testimony relating to education."

Acting Chairman KING. May I inquire whether or not you have been selected to summarize and to draw the deductions from the testimony heretofore obtained or whether you are speaking for yourself alone?

Dr. CARR. I am speaking in part for myself alone, and in part as a representative of my colleagues. We met at noon yesterday, and my colleagues asked me to do this. I did not have an opportunity to submit my statement to them.

Dr. ANDERSON. The "Summary of Testimony Relating to Education" will be admitted to the record as an exhibit.

(The document referred to was marked "Exhibit No. 2736" and is included in the appendix on p. 17515.)

Acting Chairman KING. Proceed.

USE OF EDUCATION FOR RECOVERY

Dr. CARR. Education, provided it is right in amount, in kind, and in distribution among the people, can and will improve the economic well-being of the American people.

That, I think, is our central conclusion, and the evidence is drawn in part from the recent report of the Educational Policies Commission on Education and Economic Well-Being, from other reports of the Commission, and from this study of citizenship education which we have just completed in 90 schools.

Now, this committee is interested in how that generalization might be applied in actual things to do, and I have attempted to set down in this summary some of the things which ought to be done in order to make this generalization effective in American life.

First, the American people should encourage qualified youth to remain in school through the legal school-leaving age, and beyond, if possible, by: (a) development of technical and vocational schools at the upper high-school and junior college levels—Dr. Wright pointed out yesterday the shortage of such agencies; (b) by the provision of scholarships by public initiative, such as the National Youth Administration, and through private philanthropy; (c) by adapting the course of study to individual needs.

I am afraid that sounds like a pedagogic axiom to you gentlemen, and I should like to put more meat into it if time permitted. I can only say very briefly that the history of our secondary schools is that of a college preparatory institution. They have now moved from college preparatory institutions into common schools, enrolling most of the people of appropriate age.

They have not been brought into the secondary schools by any campaign on the part of educators. The primary reason for their presence in the schools is economic and social forces outside of the school which have thrust them in. We are in the midst of a period now when a college preparatory institution, designed for a very small percent of the total population, is being adjusted to take care of the common needs of all the people. Just as years ago even the elementary schools were looked upon as schools that only a few people could profit by, and the ability to read and write was the mark of a learned man, so today the secondary school, formerly a school for the education of just a few people, is becoming part of the common general education that we expect all American people to possess and to enjoy.

That is what I mean by saying that we must adapt the course of study to the individual needs. We cannot continue to operate a college preparatory institution and expect it to serve the needs of all of the people.

The second general thing that we ought to do is to remove youth from the labor market—at once. This should be done, I believe, (a) by approval of the Federal child-labor amendment; (b), by fixing the school-leaving age at 16 years in every State.

This, of course, is a matter of State legislation in which the Federal Government cannot take a part. Some States have already reached that limit; a few have exceeded it. All should move to at least 16 years.

That is about 10 years of schooling. Ten years of schooling, gentlemen, is not too much to equip boys and girls to deal with the problems

of this society. Every boy and girl becomes a voter, and in an ideal democracy a participant in the affairs of his country.

We should improve the enforcement of school attendance laws, especially for children in industrialized agriculture and street trades, and other occupations.

The third thing we must do is to encourage revision and vitalization of economic education, first by better vocational guidance based, as Dr. Clark outlined yesterday on community and national service to determine occupational opportunities, and on surveys of individuals to determine aptitudes and abilities and interests.

The teaching profession is struggling to develop that vocational guidance program. It is a great need, and one which we have not been able to achieve yet. I should like to call your attention at this point to a chart presented yesterday, entitled "The Jobs Youth Want and the Jobs They Get," taken by courtesy of the American Youth Commission from the Maryland Youth Study.¹

The heavy line down in the center divides what youth want to do from what jobs they get. And these are proportions of all the youth studied. The top row represents the professional desires. These people on the left are the ones who want to go into the professions; the ones on the right are the group that get in. The figures on the second line, left, are the groups who want to go into the managerial operations, and the ones on the right are the ones who get in.

When we get into office work, we get a more nearly equitable balance between what they want and what they get.

The next to the last line is domestic service, and you see there a tremendously large number of people going into domestic service. Relatively few say that that is what they want to do. We believe that an honest and intelligent program of vocational guidance, without using any compulsion upon the students, can help to overcome this terrific dislocation between the hopes of young people and what they are destined to achieve.

Mr. O'CONNELL. Do you think it practical to expect that in this top group, for instance, everybody would be somewhere near in balance, so that the people who wanted to be in professional or technical lines could ever expect to arrive there?

Dr. CARR. In terms of "ever," perhaps, yes; but in terms of any reasonably immediate future, no.

There is always going to be this ambition to rise, but I would like to point out that this so-called ambition to rise in the professions is due partly to the halo of prestige which attaches to professions and partly to the fact that the professions are, on the whole, very much better off economically. So that if anything were done to increase the number of persons in the professions, thereby reducing the average earnings in the higher-paid professions, that differential would tend to disappear.

I can imagine, for instance, that if I could take a group of high-school students and tell them, "If you will go into domestic service you can look forward to \$25 a week," that situation which I showed you on the chart would not exist, in quite as great a degree, at least.

¹ See "Exhibit No. 2712," appendix, p. 17479.

Acting Chairman KING. Don't you think that a good deal of our education—I will modify that—don't you think that some segments of our educational teaching and development do not emphasize sufficiently the dignity of labor?

Now, I have been a laboring man, and some of the wisest men, some of the most patriotic men, some who have been the most useful to the moral and spiritual development of this Republic, were men who worked with their hands.

I think that too many of you educators devote too much time to what you call the intellectual and cultural things, and, of course, a man can be cultivated and be intellectual and work on the farm, in the coal mine, or do any form of manual labor.

I was reading this morning in the paper of a young man 37 years of age in England who has written the best work this last few weeks, and when the reporter went to confer with him he found him in the barnyard milking the cow. But he was cultured, he had read, he was a thinker, and yet he wanted to remain on the farm and work with his hands and develop the soil and make contribution to the material as well as to the moral and spiritual development of this country.

I think you educators—I beg your pardon, I fear sometimes that the educators have fallen a little short in emphasizing what might be termed the fundamental things in life.

INCREASED EMPHASIS ON SKILLS

Dr. CARR. I think, Senator, that education is subject to such stricture in part, and I notice you have limited it to part. I will say—and I expect you would agree—that I do not think it is a matter of choosing between this emphasis on the dignity of work and an equal emphasis on the cultivation of the mind and of the spirit. Indeed, what you said indicates you would like to see both developed concurrently.

Booker T. Washington, I think it was, said that his race would prosper in proportion as they were able to put brains, spirit, and ability into the common manual tasks. I think his viewpoint, while it is not representative of the entire teaching profession, is becoming quite representative. I think if you could have talked with the many thousands of teachers as we have in the last few years in this civic study, you would be quite encouraged by the shift that has taken place.

Acting Chairman KING. The old Romans had an expression which I think you teachers ought to emphasize, *Laborare est orare*—labor is worship. Too many of you teachers and too many of these dilettantes look down a little upon the laboring man, the man who works in the mines and the mills and on the farm. Labor is worship.

Dr. CARR. Of course, that "looking down" is a reflection, Senator, of what the rest of the culture does. It is not exclusively in the schools. After all, when a laboring man leads a most precarious economic existence with little or no security, it is not to be wondered at that boys and girls do not rush eagerly into the unskilled and humble tasks.

Acting Chairman KING. Proceed.

Dr. CARR. The question of guidance, to which I referred a few moments ago, is illustrated in this exhibit.¹ These are various groups

¹ See "Exhibit No. 2713," appendix, p. 17480.

of the youth population, showing the proportion which have received guidance in the schools with reference to the choice of a vocation, and the proportion which have not. The group on the right is the proportion which have not. The school people would like to change that. We think that the revision and vitalization of economic education should involve vocational training and that this training should utilize the public schools, industry, labor, private efforts—wherever we can get help in this gigantic job we ought to use it.

We think this should involve consumer education, and I understand if there is time the committee will hear another witness in the field of consumer education.

We think that this education should involve conservation education, development of an understanding of the resources of our country and of the importance of using them wisely.

We think that health education in our schools is a very important measure toward the development of economic well-being. The figures on the loss of income due to illness, to incapacity of one kind and another, are staggering, and we think that health education which will teach young people to maintain their health wisely is a real contribution to the economic well-being of the country.

Acting Chairman KING. That is being emphasized more and more in our public schools, isn't it?

Dr. CARR. Yes, sir; quite right, very hopefully so.

Acting Chairman KING. As chairman of the District Committee I can say we are emphasizing it in the District of Columbia, and doing all that we can to bring to the attention of the children the importance of health.

Dr. CARR. Yes, sir; that is true, I know that is so.

Finally, there should be vocational retraining for workers displaced by illness or accident or technological change. That will pay big dividends to the country as a whole, far beyond the relatively small cost of providing the training.

Mr. MAGINNIS. Dr. Carr, the chart that you had a few minutes ago showed the relative number of youths or young people desiring to enter the professions and the number who enter.¹ There is quite a decided difference; I should say offhand about one-eighth, roughly. Is that correct? Are those based on figures of any kind?

Dr. CARR. Yes, sir. These figures are based on interviews with young people in school and young people who have finished school and secured employment.

Mr. MAGINNIS. Now, considering the situation as it exists today, many, you might say 100,000, young people would be turned out each year, with the difficulty of absorbing them into the professions. Wouldn't it be well, in your judgment, if perhaps the plan along educational lines was directed further into vocational rather than professional lines? Might that not be desirable?

Dr. CARR. In the skilled trades I believe that would be so. However, all the figures we have been able to bring together (I am not sure they would coincide with the figures of this committee) indicate that the proportion of unemployment among unskilled and semi-skilled occupations is much greater than unemployment in the professions. That is, the competition for a job is greater in the unskilled

¹ See "Exhibit No. 2712," appendix, p. 17479.

group. If you want to lessen that competition at its worst point it would appear to be desirable to move qualified people, and only qualified ones, up into the higher branches of vocational and professional training.

Mr. PIKE. You notice, Dr. Carr, that the four eminent jurists on this side of the table are trying to keep new competition from entering their profession.

Acting Chairman KING. I should supplement my friend's statement by saying that the earnings of the lawyers throughout the United States only a few years ago were less than \$800 per year and during this depression many lawyers are upon relief.

Dr. CARR. Yes, sir.

Acting Chairman KING. I think the earnings by and large of many of the lawyers have been less than of some of those who worked on the farm or in the mines or elsewhere.

Dr. CARR. I am quite sure that is so.

Acting Chairman KING. The legal profession hasn't been so profitable to the great mass of the lawyers.

Dr. CARR. That is true of all professions, isn't it?

The fourth point I wanted to emphasize is that education for economic citizenship may be improved by giving public support to the discussion of important economic issues in secondary schools, in colleges, and in adult forums; second, by improving the preparation of teachers; and third, by supplying much better teaching materials and more of them, including textbooks, recordings, pamphlets, motion pictures, and other means of instruction.

Again, if you could have visited these schools with us you would have been struck time and time again with the sight of eager qualified teachers trying to do their work without tools, not only because the school board didn't have the money or was unwilling to supply the tools, but because the tools of instruction haven't been fashioned yet in this economic sphere. That, of course, I realize is not a matter of legislation.

Fifth, we should use free education as one of the means to improve the Nation's economic well-being by removing the artificial and financial barriers which now debar many youth of real and proved ability from advanced training which would greatly benefit them and society. If I could leave just one point with you I would certainly choose that one.

An exhibit already entered in the record is a picture of why youth leave school.¹

WHY YOUTH LEAVE SCHOOL

Dr. CARR. These are based on the responses of the young people themselves, which may not be wholly reliable, but which were taken by skilled interviewers and I believe to be substantially accurate. The division in the chart here is between males and females. The long bar at the top is the youth who said that they had left school because of lack of funds. You notice the immediate drop to the other points. I shall not discuss the chart in detail, but these young people, many times of unquestioned ability, who are being allowed to go to seed,

¹ See "Exhibit No. 2710," appendix, p. 17477.

represent a wastage of human resources which this country ought not to tolerate. We don't know how many Pasteurs, how many Edisons we are throwing away for lack of opportunity. Now I know it will be said, "Well, if he has it in him it will come out," but I have yet to see the evidence of that. There are plenty of cases, of course, of poor boys struggling upward and making a great deal of themselves, but there are many, many cases where if you give a youth a small scholarship, some small amount of assistance which will enable him to go to school, he will become a contributor in a very large way to the economic well-being of the country. We have abundant evidence on that in the report which Dr. Norton referred to yesterday.

We should also use free education as one means to improve the Nation's economic well-being by destroying the monopoly or partial monopoly in certain occupations by opening up training opportunities. I know the technical and political disadvantages of that problem, but it seems to be the desirable thing to do.

Sixth. Let America proceed to make good on the claim that this is a land of equal opportunity. In order to do that, there will have to be, in the first place, provision for State funds to reduce the inequalities of educational opportunity among the districts. You can go to schools within the boundaries of the same State, where the legislature of that State is mandated by its constitution to provide a free and equal educational opportunity, and yet see the most striking differences in educational opportunity; situations where the buildings, the teachers, the equipment, everything in one school is incomparably inferior to that in the other school. I do not advocate, Mr. Chairman, identity of educational opportunity for the people of America. I do not advocate that a community with a great burning desire to do an exceptionally good job by its children should be told, "No; you can't do that; you must chip into the common treasury." I do advocate a reasonable minimum of educational opportunity for every child born under the American flag. Until we come to grips with that problem, we are just not making good on the American promise.

We ought to have Federal equalization of educational opportunity among the States. Evidence has been introduced before various committees of Congress time and again which, in my judgment, leaves no doubt that there are in the United States whole areas which, with the best intention in the world, cannot finance an educational system at a reasonable minimum of effectiveness. The only agency that can remove those difficulties is the Federal agency, and our experience has been that that can be done without the interposition of Federal control or dictation in any undesirable way on the school.

We ought to have effectively free education. I have already referred to that. By effectively free education, which we do not have now, I mean education provided in such a manner that the lack of money on the part of a youth or his parents will not of itself debar him from securing that education. We do not have effectively free education now.

The last two points are in the nature of exceptions.

Seventh. I just want to make the point that we in education recognize fully that many factors, many causes, affect the economic well-being of this country. We are not so overcome with the importance of our profession as to suppose that we have the exclusive key to the answer that this committee is seeking. We do believe that education is

only one factor, but an exceedingly important and powerful factor, a good lever to put under the inertia of this economic system and get it rolling in the direction we want.

Eighth. I would like to say that education has many highly important values other than the economic values, Senator, you were referring to this yesterday. An emphasis on the economic values of education, which we have selected here for emphasis because we understood that was the committee's primary concern, does not in any sense ignore or minimize these other values of education.

Acting Chairman KING. Thank you very much. Are there any questions?

Dr. ANDERSON. Thank you, Dr. Carr.

(The witness, Dr. Carr, was excused.)

Dr. ANDERSON. The next witness is Mr. Kennedy, who will discuss technology and its effect in the coal industry. Before this, gentlemen of the committee, we have presented representatives of two groups, management and labor, in the particular industries under review. Because this is the final day of testimony and we are attempting to rush this thing through today, we have asked the witnesses to be as brief as possible and to file as much of their material as they can. In this connection, management has been very cooperative, and Mr. Charles O'Neill, president of the United Eastern Coal Sales Corporation, expressing the point of view of management, has very kindly agreed to file his statement in toto with the committee and not make a personal appearance.

At this time, Mr. Chairman, I should like to submit his statement to the committee to be incorporated into its deliberations as if read.

Acting Chairman KING. Any objections? It will be received.

(The document referred to was marked "Exhibit No. 2737" and is included in the appendix on pp. 17516-17535.)

Dr. ANDERSON. The next witness for the coal industry is Thomas Kennedy, secretary-treasurer of the United Mine Workers of America, and with him is associated Dr. Walter Polakov, director of the engineering department of the same organization.

Acting Chairman KING. Do you and each of you solemnly swear that the testimony you are about to give in this proceeding shall be the truth, the whole truth and nothing but the truth, so help you God?

Mr. KENNEDY. I do.

Dr. POLAKOV. I do.

**TESTIMONY OF THOMAS KENNEDY, SECRETARY-TREASURER; AND
WALTER N. POLAKOV, DIRECTOR, ENGINEERING DEPARTMENT,
UNITED MINE WORKERS OF AMERICA, WASHINGTON, D. C.**

Dr. ANDERSON. Mr. Kennedy, what is your position at the present time?

Mr. KENNEDY. Secretary and treasurer of the United Mine Workers of America.

Dr. ANDERSON. Is that an affiliate of the A. F. of L. or the C. I. O.?

Mr. KENNEDY. C. I. O.

Dr. ANDERSON. How many mine workers are organized in your United Mine Workers organization?

Mr. KENNEDY. Six hundred thousand.

Dr. ANDERSON. How many mine workers are there in the entire country mining coal?

Mr. KENNEDY. We figure approximately somewhere in the neighborhood of 650,000 or 660,000.

Dr. ANDERSON. So that you are speaking for the vast majority of coal miners in America.

Mr. KENNEDY. I believe so.

Dr. ANDERSON. Dr. Polakov, you are an engineer?

Dr. POLAKOV. I am a management engineer.

Dr. ANDERSON. How long have you been engaged with or related to the United Mine Workers organization?

Dr. POLAKOV. I am director of their engineering department and have been for a little over 3 years.

Dr. ANDERSON. And both of you have been studying this problem of the impact of technology on mine workers and mining?

Dr. POLAKOV. That is right.

Mr. KENNEDY. Yes.

Mr. CHAIRMAN. I have prepared a summary of the facts and data which are contained in this table which will be filed with the committee.

Acting Chairman KING. It will be received.

(The document referred to was marked "Exhibit No. 2738" and is included in the appendix on pp. 17536-17550.)

Mr. KENNEDY. Coal mining has been considered a sick industry for many years. As far back as March 1932, the U. S. Supreme Court, in the case of Appalachian Coals, Inc., took cognizance that "unemployment mounts and communities dependent upon profitable production are prostrated."

The United Mine Workers of America have consistently supported measures tending to stabilize the coal industry. They sponsored the National Bituminous Coal Act, the establishment of minimum prices, and in every other way possible have been helpful.

While this legislation has as yet not had a chance to operate, it is safe to say that the force of technology is closing the economic scissors that cut the life line of employment on which hundreds of thousands of coal miners precariously hang.

One blade of these scissors continually cuts the number of men needed to produce each ton of coal, while the other blade cuts the number of tons needed to carry on industry, transportation, and the generation of heat, light, and power.

INCREASED PRODUCTIVITY

Mr. KENNEDY. The technology of coal mining has steadily increased productivity of labor from less than 3 tons (2.98) per day in 1900 to 4.6 tons in a much shorter (23.9 percent) workday in 1938. Since the advent of mechanical loading, the time needed to produce 1 ton of bituminous coal has been shortened by 17 minutes; this means that 15 years ago the production of 1 ton of coal required 18.6 percent more time.

Such speeding up of production would have eliminated 131,000 jobs in and around the bituminous mines of this country, but due to the reduction of hours, the reduction of the number of days mines operate within a year (in 1929 mines operated 219 days, in 1938

only 160 days), and the sharing of work among miners, the total disemployment from mechanization and other means of increasing labor productivity was actually 75,715 men in the bituminous coal industry. This number of men and their families were denied the right to work within the 15 years from 1923 to 1938.

In the anthracite field, while mechanization and the general rise of labor productivity were even more pronounced, showing an increase of 48.3 percent in hourly productivity per man, the total disemployment due to this cause was less—about 2,500 men displaced by mechanization—within the same period, because the reduction in the number of days operated per year was in about the same proportion as the increase in productivity per man-day.

The total elimination of jobs by technological changes in labor productivity reached during the last 15 years the ominous figure of 78,140 men.

During the same period (1923-38) the consumption of coal was gradually reduced by 219,000,000 tons of bituminous coal and by 47,200,000 tons of anthracite.

Acting Chairman KING. Was that reduction in part due to the increased consumption of gas and oil?

Mr. KENNEDY. Yes. I come to that later on, Senator, I have that all worked out.

This reduction of coal consumption is not due to the economic depression alone. As a matter of fact, our total energy consumption increased 20.8 percent—from 21,308 trillions of heat units (B. t. u.) in 1921-25 to 25,739 trillions of heat units in 1937.

The principal cause of the reduced coal consumption has been technological progress in almost every engineering activity.

Wherever coal is used, it is used in smaller quantities for securing the same results. Mechanical stokers, pulverized coal burners, automatic combination controls, economizers, preheaters, and so forth, greatly enhance the efficiency of steam generation.

The use of steam produced with a smaller quantity of coal is in turn made more efficient by the use of high-pressure, high superheat steam, better pipe insulation, the use of regenerators, superheaters, and so forth. Steam engines gave way to three-stage steam turbines of greater efficiency. The wider use of electric current from large and economical central stations took the place of isolated plants of lower efficiency. Thus public utility plants alone reduced their coal consumption by 40.4 percent per each kilowatt-hour generated.

Likewise in railroad practice modern locomotives, improved roadbeds, roller bearings, and so forth, reduced coal consumption 22.0 percent per 1,000 ton-miles of freight moved, and by over 15 percent per passenger car-mile.

In the cement industry coal consumption per barrel of cement was reduced by some 20 percent, and in pig iron production by 14.6 percent, and so on through achievements in various branches of engineering.

Domestic heating is no exception—the development of domestic stokers, of automatic combustion and heat regulators, and the more efficient insulation of houses has considerably reduced this important market for coal.

Translating these economies in coal utilization into the number of men needed to mine the coal which is no longer required, we get

another group of 34,000 miners who lost their jobs due to engineering efficiency in coal utilization within the last 15 years.

At the same time the technique of geophysics has made noteworthy strides in locating new oil and gas wells. Whereas we knew of only 15 to 20 years of oil reserves at the close of the World War, we are now reasonably certain of 30 years of an increased supply of these substitute fuels. Along with the opening of new oil and gas fields, perfected methods of recovery have increased their yield.

This yield of crude oil is refined by technically improved processes, and this increased production of gasoline is accompanied by an increased output of fuel oil and Diesel oil.

Mr. PIKE. I think I would have to take a little exception on that point, Mr. Kennedy. There is an increase in the total over a long period of years due to a great increase in the total amount of oil put through the refineries, but by and large the proportion of fuel and Diesel oil from the barrel is rather less than it was. After you have built up your gasoline, say, to 45 or 50 percent of the total of the barrel of crude put in, as against perhaps a natural yield of around 25 or 27, as a rough guess, a good deal of that increased production of gasoline comes right out of the fuel and the burning oil cut.

Mr. KENNEDY. Is that under the new process?

Mr. PIKE. Under the new process I think they burn all the gasoline.

Acting Chairman KING. Does the engineer desire to make an observation?

Dr. POLAKOV. We have it worked out in our figures here.

Mr. KENNEDY. Our figures show an increase.

Mr. PIKE. In the total number, yes; but it is a rather decreased proportion. Of course, the oil industry has grown very substantially over the period. That is the only exception I wanted to make.

Mr. KENNEDY. Residual oil (fuel, gas, Diesel) is not, in our judgment, priced in proportion to the cost of production, but fuel oil is subsidized by gasoline sales. Thus, technological advances in the petroleum industry have made it possible to put liquid fuels on the market in competition with coal.

Diesel-engine installations by 1940 represent over 15,000,000 horsepower, which otherwise would be largely generated by coal. Fuel-oil consumption increased between 1923 and 1937 by 84,000,000 barrels. This amount of fuel alone replaced nearly 15,000,000 tons of coal and eliminated the jobs of at least 16,000 miners.

The technology of natural-gas production and transportation has likewise made great strides and offers for sale this substitute for coal at somewhat advantageous prices. While only a portion of the natural gas enters into direct competition with coal or with manufactured coal gas, the portion has grown tremendously. Some 530,000,000,000 cubic feet of natural gas have displaced coal in domestic and industrial uses. This quantity is equivalent to some 22,000,000 tons of coal. The resulting elimination of jobs which would have been necessary to mine this tonnage put about 24,000 miners out of work.

Last, but not least, important technological progress has been made in the design and construction of hydroelectric plants. In 1937 nearly 44,000,000,000 kilowatt-hours were produced by water power. Coal

burned for this purpose would have given employment to 34,500 miners. The increase in hydroelectric output between 1925 and 1937 alone is equivalent to over 6,000 miners' jobs.

Acting Chairman KING. The Government then through T. V. A. and these hydroelectric plants constructed by the Government are in competition with the coal mines.

Mr. KENNEDY. In a certain sense; yes.

To summarize this technological displacement of miners within the last 15 years, we add these groups by causes of disemployment.

Mechanization and increased productivity of labor.....	78,140
Increased efficiency of utilization.....	33,950
Substitute fuel oil.....	16,100
Substitute natural gas.....	23,900
All hydroelectric power.....	34,540
Total.....	186,630

The unaccounted-for balance of disemployed miners may be due to some extent to the conservatism of the above calculation. It is reasonable, however, to presume that these remaining unemployed lost their jobs because of the economic depression, which reduced industrial production and transportation as well as compelled a large section of our population to economize on heating their homes, illuminating their rooms, and otherwise curtailed their former standards of living.

DECLINE IN EMPLOYMENT

Mr. KENNEDY. Statistics of the United States Bureau of Mines indicate that the total shrinkage of employment between 1923 and 1937 was:

In bituminous mines.....	<i>Men</i> 214,022
In anthracite mines.....	58,553
Total.....	272,680

By 1938 this figure on unemployment reached a still higher level of 297,250 men. Therefore, the unemployment not directly allocated to technological displacement is:

Total.....	<i>Men</i> 272,680
Technological.....	186,630
Due to depression (in 1937).....	86,050
In 1938 (about).....	110,000

Of course, all of these men are not necessarily totally without work. The computation was made on the man-year basis, which in 1937 was equal to 1,372 hours of employment and in 1938 shrank to 1,120 hours per year. It is quite possible that some of these men whose work was made unnecessary by technology were sharing work with others, so that instead of 272,000 men working zero hours and 589,000 working full time, some of the men worked fewer days per week to prevent starvation of disemployed families, at the cost of undernourishing their own children.

What the future holds for employment in the coal industry is reasonably certain. Extended mechanization will continue to take its toll in men swept aside by machines. This displacement will gradu-

ally slow down until a new type of machine will again accelerate the rate of displacement.

A careful inspection of new mining equipment, as it is exhibited annually at the Mining Congress conventions, gives a much better picture of the trend in the future than all the economic compilations and legal considerations can possibly disclose. And the writing on the wall of the exhibition halls is that within a few years the productivity of labor will approximate 1 ton per man-hour.

The other blade of the economic scissors—the reduction of demand for coal—can be foreseen from the examination of engineering evidence. Little can be expected in better equipment for combustion of competing fuels. As gasoline is sold in ever-increasing quantities for motor transport, a greater quantity of fuel oil will be available and will become the chief competitor of coal unless and until new processes of oil fractioning are perfected which would yield more gasoline and less fuel and gas oil, which I think is being brought about. Natural gas may be expected to continue to compete and to displace coal wherever possible.

But deposits of both petroleum and gas are much more limited than of coal. It is officially estimated on the basis of present-day technology that petroleum deposits will last 15 to 30 years. Unless new discoveries are made within that time, competing fuels may go up in price or otherwise become restricted.

The opposing force which may retard the shrinking employment in the coal-mining industry is to be looked for in the development of the technology of coal byproducts, liquefaction of coal to derive motor fuels, and the expansion of chemical industries.

In other words, the "long view" on the situation of the present ravages of technological disemployment offers some solace that perhaps in the not distant future new industries will spring out of new technology or multiple production, using coal as a raw chemical as well as a crude fuel.

In the meantime the United Mine Workers of America believe that the Federal Government should give some consideration to the matter of assisting the bituminous and anthracite industries to advance their markets and create employment. Increased employment in the mining industry constantly aggravates the national unemployment situation and is a vital factor in that problem.

Acting Chairman KING. May I interrupt you, Mr. Kennedy? I am very much interested in the suggestion you have just made about the obligation or duty upon the part of the Federal Government to find means for a larger utilization of coal. Will you elaborate that point a little, if you care to?

Mr. KENNEDY. Yes.

As against competing fuels, labor plays a very important part in the production of coal, as evidenced by figures showing the relation of labor costs to the total cost of producing various goods in this country. Oil, gas, and so forth, come from practically laborless industries.

Now, fuel oil is one of our serious competitors in the coal business. We have made constant overtures to the Federal Government to put an excise tax on the imports of oil. We have had up with the Federal Government the question of taxes in these so-called trade agreements with foreign countries, for instance the Venezuelan

Trade Agreement. We made overtures to the Department of State urging that nothing be done to interfere with the tax on Venezuelan oil. We believe it should be taxed. Well, they reduced the tax on that oil. We believe, in connection with the Canadian agreement, that something could be done to facilitate the sending of our coal into Canada. There is a tax of some 50 or 60 cents on a ton now against American coals into Canada. That was reduced very little in the last agreement.

Mr. PIKE. They have some mines of their own to protect, haven't they, Mr. Kennedy?

Mr. KENNEDY. But they don't protect them. The Canadian mines have a potential productive capacity of about 50,000,000 tons a year. They consume from 90,000,000 to 100,000,000 tons in Canada, but the former Canadian Government, that is, the Bennett government, made a trade agreement with Great Britain in which they subsidized Great Britain's coal even against Nova Scotia and British Columbia coal, and against our coal. So that anthracite lost about 2,000,000 tons of a market that it had in Canada as a result of those trade agreements. I mean the agreement between Canada and Great Britain and the tax that is levied against American coals by Canada.

Mr. PIKE. That probably goes into the shipping situation to some extent.

Mr. KENNEDY. I think it does to some extent.

Mr. PIKE. To give perhaps a boat for grain from England to Canada.

Mr. KENNEDY. I was personally acquainted with Mr. Harrington, of Nova Scotia, at that time, and I got the impression that the coal industry in Canada was sold out in the interest of the grain and fruit industries.

Mr. PIKE. The maritime provinces frequently had that feeling.

Mr. KENNEDY. That is right.

Somewhere along the line, recognition of this factor must be accepted by the American people and by the Congress. Legislation contemplating equalizing taxes on competing fuels and imports of oil and solid fuels, together with the possibility of taxation and regulation within the realm of labor-saving machinery, may be pertinent and necessary.

In this connection, of course, the United Mine Workers are strongly on record apropos of the convening of a national meeting by the President or by Congress in which labor and industry and finance might be represented, and which should give some consideration to an approach of this problem of unemployment and its solution.

In any event we believe Congress should do what is necessary to bring about a national economy that will put our unemployed back to work on a basis of hours that will be geared to the trend of modern industry; and wages and opportunity for earning that will bring about sufficient and adequate purchasing power to provide for continuing steady employment and prosperity in this Nation.

Acting Chairman KING. Thank you very much, Mr. Kennedy. Are there any questions?

Dr. ANDERSON. I think Mr. Polakov was to read his statement following, or are you to insert it in the record?

Mr. POLAKOV. I leave it to the committee whether they want to hear a somewhat different approach to the subject from the engineering point of view, or insert it in the record.

Acting Chairman KING. How many more witnesses have we?

Dr. ANDERSON. One more this morning.

Acting Chairman KING. How long will it take?

Mr. POLAKOV. Twenty minutes.

Acting Chairman KING. This is a very interesting subject. I would like to hear the engineer.

COMPETITION OF COAL AND GAS

Mr. PIKE. May I ask a question of Mr. Kennedy? This matter of competition between gas and coal is a very difficult thing. Gas, as you say, in its inception is almost entirely a laborless industry. There is a great waste of gas going on in our Southwest, considerable waste, let me put it, which our National Resources Commission want stopped, and I think we would all like to see stopped. So we have a Federal interest in utilizing that gas. At the same time it is utilized, it comes right in to your product and competes more.

Under this present bituminous law, we have a stabilized price of coal at or a little bit higher than the rate it has been selling at, let's say, over the last 2 or 3 years. In the meantime, another agency of the Federal Government is trying quite hard to get down the prices of delivered natural gas. If those prices come down, natural gas displaces more coal.

It is pretty contradictory, it seems to me, and I wondered what your reaction was.

Mr. KENNEDY. I have an idea that somewhere along the line there has got to be a correlation of these prices in the industries affecting all kinds of fuel, solid, liquid, gas—it just doesn't make sense.

Mr. PIKE. The thing you said is very true; our resources of gases and oil are quite limited. The National Resources Planning Board estimates there is the equivalent of about 4,000,000,000 tons of coal in sight in form of oil and about the same heat value in the form of natural gas. There will be more of these discovered, of course. On the other hand, 2,500,000,000,000 tons of coal are in sight. The difficulty of competition is probably just a matter of this generation, but it doesn't help this particular generation very much.

Mr. KENNEDY. That is true in Pennsylvania during the administration that I was associated with over there; we kept natural gas out of Pennsylvania; we wouldn't permit to enter there. I don't know what the present administration is going to do, but we are in hopes they will continue that policy.

Dr. ANDERSON. Mr. Kennedy, your competition with other fuels is made more serious, isn't it, but isn't the coal by the highly competitive nature of the coal industry—some 6,000-odd units fighting over price?

Mr. KENNEDY. It is very highly competitive.

Dr. ANDERSON. That is one of the major problems that you face in attempting to solve the employment problems of the workers in the industry?

Mr. KENNEDY. It was one of the problems that we faced, and which we hope has been solved by the enactment of a National Bituminous Coal Act in the publication of prices. We think that may help to solve that problem.

Dr. ANDERSON. Is there any feeling that one of the ways to solve at least part of the coal problem is to unify the industry into larger, more monopolistic groups?

Mr. KENNEDY. Well, I don't know; we had that situation in anthracite, where they had virtually a monopoly up until 10 years ago, and since that time it has disintegrated. We now have less monopoly there than we ever had.

Dr. ANDERSON. In other words, when industry was unified, you could get at the problem quicker.

Mr. KENNEDY. Much better.

Mr. O'CONNELL. It was that disintegration, I take it, that was in part responsible for the Pennsylvania Bituminous Coal Act.

Mr. KENNEDY. That is true, but we do not have any such act in anthracite.

Mr. O'CONNELL. Are there many competing units in the anthracite field?

Mr. KENNEDY. More now than ever in its history; we probably have 200 or more units there now where we formerly had about 60 or 65.

Acting Chairman KING. Has the number of units increased by reason of developing new anthracite coal mines, or by a division of the former areas of coal?

Mr. KENNEDY. We had very keen competition in prices there for a number of years, and a lot of companies folded up and leased their mines out to individuals. There are a greater number of independent operators now.

Dr. ANDERSON. Mr. Kennedy, we had testimony concerning what is occurring in steel towns as a result of a new stripping process, and closing down of old mills. I understand that you have also faced that in the plight of the coal miners, and that has been met by closing of mines.

Mr. KENNEDY. We have a number of those cases. Dr. Polakov can touch on them. Right in my own State, up in the anthracite regions, we have many ghost towns.

Dr. ANDERSON. Is the problem being accentuated, or growing less?

Mr. KENNEDY. Well, I don't know; it is not being aggravated. The loss of employment by thousands of miners in certain sections of the anthracite really brought on the so-called bootleg mine problem, because the whole community was lost by shutting down all the mines in a given territory.

Dr. ANDERSON. I understand in England they have finally come to the conclusion that they have to move whole populations. What is your judgment on stranded populations and the possibility of moving them?

Mr. KENNEDY. I was in England last year at the miners' convention there in South Wales. That was the really bad area in England, South Wales. Since the war, that problem has sort of disappeared, rather since they started to prepare for the war. The Government had built manufacturing establishments in some of those Welsh valleys, which meant industries. That was working out pretty well until

the war reached them, and now the mining industry is working full blast, together with steel and all other industries in that section of England.

Dr. ANDERSON. The Government had to intercede to the extent of actually going in with capital equipment and building factories, inviting new industries to engage in their business there and by so doing, link the factor of coal to industry.

Mr. KENNEDY. That is right, right in those valleys.

Dr. ANDERSON. How realistic is such an approach in the solution of our problem here?

Mr. KENNEDY. I think it offers something, especially in the mining area.

Dr. ANDERSON. All right, Mr. Polakov.

Acting Chairman KING. Mr. Kennedy, we appreciate very much the contribution of this important subject.

Mr. KENNEDY. We have a gentleman here from the Pittsburgh district who lost his job the other day as a result of the introduction of machinery. Do you care to question him, or see him, or talk to him? This is Mr. Renton.

Acting Chairman KING. Do you solemnly swear the evidence you are about to give in this hearing shall be the truth, the whole truth, and nothing but the truth, so help you God?

Mr. RENTON. I do.

TESTIMONY OF WILLIAM RENTON, OF COVERDALE, PA.

Mr. KENNEDY. Where do you live?

Mr. RENTON. Coverdale, Pa.

Mr. KENNEDY. It is in Allegheny County. How old are you?

Mr. RENTON. Forty-six years old.

Mr. KENNEDY. What is your occupation?

Mr. RENTON. Coal miner.

Mr. KENNEDY. When did you last work?

Mr. RENTON. On the 20th of January 1940.

Mr. KENNEDY. How did you lose your job?

Mr. RENTON. By introduction of machinery.

Mr. KENNEDY. How many men were displaced at your mine by machinery?

Mr. RENTON. From the 20th of January until the present time there have been 200 men displaced.

Colonel CHANTLAND. Out of how many?

Mr. RENTON. Out of 800.

Mr. KENNEDY. Do you think your age had anything to do with your loss of employment by not going on the machines in the mine?

Mr. RENTON. My not going on the machines is the reason I am unemployed.

Mr. KENNEDY. They usually put younger men on machines?

Mr. RENTON. Yes, sir.

Mr. PIKE. You mean they think you are too old to go on?

Mr. RENTON. On going around to the other mines, 45 years practically is the limit to go on a machine.

Mr. PIKE. They are apt not to hire a man over 45, or apt not to keep him if they bring machines in.

Mr. RENTON. That is right.

Mr. O'CONNELL. Generally speaking, were the men let out—the older men?

Mr. RENTON. Mostly older men; yes, sir.

Mr. KENNEDY. What are you doing now, Mr. Renton?

Mr. RENTON. I am not employed at the present time.

Mr. KENNEDY. Have you employment insurance compensation?

Mr. RENTON. I did up until last week.

Mr. KENNEDY. That is given for 13 weeks in Pennsylvania, is it not?

Mr. RENTON. Yes, sir.

Mr. KENNEDY. And you are finished on that. What are you going to do now, from now on after your insurance runs out?

Mr. RENTON. Well, I will have to go—these last few months I have been trying to get employment with these other mines, but I have been unsuccessful, and about the only thing left now is to try and go on relief, and I don't want to do that.

Mr. KENNEDY. Do you own your own home?

Mr. RENTON. Partially I do.

Mr. KENNEDY. You are paying for it on the installment plan?

Mr. RENTON. That is right.

Acting Chairman KING. Have you a family?

Mr. RENTON. Yes, sir; 3 children.

Mr. HINRICHs. Was this January the first time you have ever drawn unemployment compensation? Have you had unemployment compensation before?

Mr. RENTON. I did last year, in April.

Mr. HINRICHs. How long were you out in April?

Mr. RENTON. Seven weeks, at the time of the strike.

Mr. HINRICHs. And you hadn't drawn compensation before that?

Mr. RENTON. Yes sir.

Mr. MAGINNIS. Were you paid any wages at all when you were let out because of machinery?

Mr. RENTON. No sir; except the unemployment compensation.

Dr. ANDERSON. But you were paid no dismissal wage when machinery was installed in your coal mine and you were dismissed?

Mr. RENTON. No; unless we had earned it.

Dr. ANDERSON. I mean dismissal wage.

Mr. RENTON. No sir.

Dr. ANDERSON. Do you know of any such among your acquaintances or work in the coal mines?

Mr. RENTON. I do not.

Dr. ANDERSON. And when you go from one mine to another and apply for work what do they tell you?

Mr. RENTON. Well what they have told me is that they are sorry they are laying men off and putting machines in. That has been my answer all through the valley.

Dr. ANDERSON. You look like a perfectly healthy and strong man. Why is it you can't handle a machine?

Mr. RENTON. I haven't had an opportunity to handle the machine because I can't be reemployed.

Dr. ANDERSON. But you could handle a machine.

Mr. RENTON. I could.

Dr. ANDERSON. Why do they want younger men to handle the machine?

Mr. RENTON. The way I see it, they can mold the young men to what they want them to do more than an older man.

Dr. ANDERSON. You mean it will take some time to train a man to handle a machine?

Mr. RENTON. On these big machines; yes.

Dr. ANDERSON. And you don't think a man of your age can learn just as well and rapidly as a young man?

Mr. RENTON. I certainly do.

Dr. ANDERSON. Who thinks differently?

Mr. RENTON. The foreman thinks differently on that.

Dr. ANDERSON. Well, when these young men are taken in your place, are they taken from miners already at work in the mines, or are they taken from outside unemployed workers?

Mr. RENTON. They are taken from the lads in the mines.

Acting Chairman KING. They didn't bring in new men?

Mr. RENTON. No, sir.

Acting Chairman KING. They took the younger men who were working in the mine?

Mr. RENTON. That is what they only partially did. They brought in some other men when they started that first, some cutters, we called them, that cut the coal. We didn't have enough at the mine at that time to take those positions.

Acting Chairman KING. Then the new men brought in were persons that had skill that none in the mines possessed.

Mr. RENTON. That is right.

Mr. HINRICHS. How many years have you been employed by the company?

Mr. RENTON. Since 1930.

Mr. HINRICHS. So that you have been with them for 10 years.

Mr. RENTON. The past 10 years, all but 6 months. Two years ago I didn't work for 6 months, and then I was reemployed at that same mine.

Acting Chairman KING. What did you do before you worked in the mine?

Mr. RENTON. Before I came back to this mine, I was sealing mines.

Mr. KENNEDY. That is sealing up abandoned mines.

Acting Chairman KING. You have been in the coal mining business many years, then.

Mr. RENTON. Yes, sir; the last 30 years I worked in the coal mines.

Acting Chairman KING. In Pennsylvania?

Mr. RENTON. No; since 1914 in Pennsylvania; I came to Pennsylvania in 1914.

Acting Chairman KING. You came from Wales?

Mr. RENTON. From Scotland.

Mr. HINRICHS. Had any of the younger men who are kept on in the mine been with the company for a shorter period than you had been?

Mr. RENTON. Absolutely.

Mr. HINRICHS. Men who had been there for only 2 or 3 years?

Mr. RENTON. That is right, sir.

Mr. HINRICHS. So that you weren't protected by any form of seniority.

Mr. RENTON. That is right.

Mr. HINRICHS. And seniority protection would have protected you as a particular individual?

Mr. RENTON. That is right.

Colonel CHANTLAND. What do these machines consist of?

Mr. RENTON. Well, it is a conveyor system. The machine goes in on the coal face and takes the coal up a boom and enters it onto the car. Then they have other types that go in with a shaking system that does practically the same thing, but it is a different kind of machine.

Colonel CHANTLAND. Mr. Kennedy, how nearly typical is this man's example throughout the industry—I mean how many instances of this has occurred within this short time that he speaks of—during the last 15 months?

Mr. KENNEDY. There is quite a lot of it in the bituminous, for one of the reasons advanced by Mr. Hinrichs. In many sections we do have seniority rights. In a lot of sections in the bituminous, we do not have seniority rights, especially in the newly organized fields, the coke fields in West Virginia, Kentucky, Tennessee, and other newly organized districts.

Where we have seniority, we can protect our older men; that is, men older in point of service.

DISMISSAL WAGES

Colonel CHANTLAND. What about any dismissal wages anywhere in the industry?

Mr. KENNEDY. There is no dismissal wage in the coal-mining industry that I am aware of. We have it in the chemical end of our industry, but not in the coal-mining industry.

Dr. ANDERSON. How abrupt was the notice you got? When were you told you were to be dismissed?

Mr. RENTON. I was told on January 20, and the next day was my last day.

Dr. ANDERSON. And you had no inkling that that was going to occur?

Mr. RENTON. Absolutely not; I didn't think I was going to be laid off.

Dr. ANDERSON. There wasn't any rumor afloat that the mine was going to move into mechanization and you had better get ready?

Mr. RENTON. There was to that effect, but we didn't pay any attention to it; we didn't think we were going to be laid off until the day before the assistant foreman told me, "Bill, tomorrow is your last day."

Mr. HINRICHS. Even if you had known the mine was to be mechanized and they were going to lay off workers, you as a particular individual wouldn't have known whether you were going to be one of the 200, or whether it was going to be someone else, would you?

Mr. RENTON. That is right.

Mr. HINRICHS. Your notice as an individual came before the mechanization took place.

Mr. RENTON. That is right.

Mr. O'CONNELL. Had you known it a week or 2 weeks in advance there wasn't very much you could have done about it.

Mr. RENTON. Couldn't have done a thing about it.

Acting Chairman KING. Will you proceed, Mr. Polakov?

Mr. POLAKOV. I will abbreviate.

Acting Chairman KING. Your paper will be printed if you desire.

(The document referred to was marked "Exhibit No. 2739" and is included in the appendix on pp. 17551-17557.)

Mr. POLAKOV. The economic consequences of such changed technique in mining are grave and far-reaching. With 78,000 men who lost their jobs in mines due to mechanization within the last 15 years, with a total of 187,000 displaced by all forms of changed technology, and a total of 272,000 men out of jobs, the industry and the Nation is faced with a problem of what to do with these men and their dependents, a total well over 1,000,000 people.

One director of personnel department of a typical coal company wrote to us recently, and I will read his letter.

We mine bituminous coal and employ 6,000 men. When we are fully mechanized we will have laid off about 1,000 men. I realize that the general thought is that these men will be employed in other industries, as there will be more men employed in the manufacturing of these machines. But, to start with, this type of labor, and the age of these men, will make it practically impossible for them to even do this type of work, and besides the automobile and steel plants and machine shops are reducing their personnel and have the same problem. Industry is using the best talent and research for improving its machinery so as to lower their costs and in many instances to just maintain their present business. Of course, no corporation can afford to maintain these extra men, and if industry doesn't take care of these men the government must—and in the end the industry must pay for this in the way of taxes.

-Now, that is a quotation from a letter of one of the large coal companies.

The United Mine Workers of America have favored the introduction of a 6-hour day, 30-hour week, with 200 days a year guaranteed work ever since Mr. John L. Lewis proposed this measure at the 1933 Bituminous Coal Code hearings.

When the 7-hour day, 35-hour week was finally secured, it was obvious that this measure was no longer adequate, that the securing of it was delayed too much, and it was unable to absorb the technological displacements, and again in the wage negotiations in 1939 the 30-hour week was sought but not attained.

Miners themselves, rather than see their neighbors and their children starve, frequently demand that the local management reduce the number of working days for all instead of laying off completely men whose jobs are eliminated by machines. "Work together, starve together" seems to be a motto in most of the mining camps. And work for 2 or 3 days a week instead of 5 is frequent in many localities. In other words, in such closely knit and mutually supporting communities we find that among miners disemployment appears in two forms, direct displacement by technology and indirect underemployment created by the sharing of unemployment. How great is this indirect disemployment is difficult to estimate, but it is certain that it is at least half as large as direct unemployment. That is, it affects not less than 40,000 families.

In Illinois, for instance, where mechanization of mines is more advanced, W. P. A. conducted a census in 3 counties, Williamson, Saline, and Franklin. It was found that—

a large part of the working population is completely stranded. * * * Coal miners constitute the great bulk of the worker population. * * * Mine operators have mechanized the loading of coal to the point where thousands of hand loaders have been eliminated.

Acting Chairman KING. Is there as much coal produced now as there was a few years ago, before the discharge or separation of the service of a considerable number of employees?

Mr. POLAKOV. The production of coal essentially changes with the market conditions, but potentiality or capacity for production now is greater than it has been before mechanization.

I will introduce these charts in evidence.

LABOR DISPLACEMENT BY MECHANIZATION

Dr. ANDERSON. This chart, headed "Displacements of Miners by Mechanization in Deep Bituminous Mines in the U. S. A." will be entered in the record.

(The chart referred to was marked "Exhibit No. 2740" and appears on p. 17201.)

Mr. POLAKOV. In other words, with a quantity of coal that requires three men (3.15) to produce by ordinary hand methods, which represents about 75 percent of coal production today in this country, it takes only two men with the aid of conveyers—of which the weak victim we saw a few minutes ago was one—and it takes only one man with a fully mechanized mobile loading mine.

Mr. PIKE. Are those adapted for all mines, or are there only particular mines in which they can be introduced?

Mr. POLAKOV. Theoretically speaking, they are adapted to probably 95 percent of mines. From the point of view of sound economy and sound management, it is easily applicable to 50 or 60 percent.

Acting Chairman KING. What is the character of the mechanization, the cutting of coal or hoisting it or taking it from the tunnels or from the face of the drift to the surface and unloading it there and loading it onto the cars?

Mr. POLAKOV. Well, mechanization today covers practically every phase or stage of the coal production.

Acting Chairman KING. That is—

Mr. POLAKOV (interposing). Undercutting instead of kerfing is done by the machine. Drilling is done by electric drills instead of by hand. After it is shot—and now less and less explosives are used and more and more carbon dioxide or compressed oil in rubber tubes—the coal is loaded not by shoveling into the cars but by self-loading conveyors or pit car loaders—you have probably seen them in the gravel yards and things like that—or by mobile loaders which are a combination of conveyor and a grabbing, eccentric attachment in front which grabs the broken, loose coal and loads it on the conveyor, which carries it all the way to the tipple, in some instances, or on the main haulage train, in some others.

Acting Chairman KING. Where you have a very slender layer of coal, say a foot or 18 inches or 2 feet, have you used machinery there to load that coal?

Mr. POLAKOV. In many places in Alabama and in some places in Kentucky where there are thin seams, 20 inches plus or minus, they use conveyors. Men lie down on their sides or on their backs and

shovel coal from the face on these conveyors, having only a couple of inches or a few inches above between the roof and the top of the conveyor, but still it is being done.

In central Pennsylvania, similar methods are used in low veins, the low conveyors.

Acting Chairman KING. Of course where you have very thick seams—in my State we have some seams there 6—one seam, as I recall, is some 10 or 15 feet.

Mr. POLAKOV. That is right. In your State more than 80 percent of the coal is mechanically mined and loaded, but even with thick seams sometimes it is not safe to use mechanical loading, as for instance, in the Pittsburgh seam, which has a tender roof. And the danger is increased out of all proportion.

Acting Chairman KING. They have to use a good deal of timbering, do they not?

Mr. POLAKOV. Which they usually fail to use because it obstructs the free motion of the machinery. So they take the risk of life with men.

Dr. ANDERSON. You mean the laws of Pennsylvania permit them to continue to risk human life in order to avoid proper timbering of mines?

Mr. POLAKOV. The laws are written in the books and the inspection of the mines is left to human beings.

Acting Chairman KING. There is a human factor there.

Mr. POLAKOV. That is right.

Acting Chairman KING. Proceed.

Mr. HINRICHS. On Exhibit 2739 you haven't any unit of time. I presume that those are comparable.

Mr. POLAKOV. Average day.

Mr. HINRICHS. That means a 7-hour day.

Mr. POLAKOV. Yes.

One of the most telling effects of mechanization was recorded in the town of West Frankfort, Ill. In 1930 the population of that town was 14,700 people. In 1939 it had shrunk to 12,000. During 1926 the average output per man-day in a town of 6,000 mine workers was 5.4 tons within 8 hours. By 1937 efficiency increased so that one man working 7 hours produced 8.9 tons, due to mechanization, an increase of 63.2 percent.

To equal the all-time record of coal production, West Frankfort, Ill., operators need to rehire only 700 men to replace 3,000 men displaced.

Another case is reported in Ziegler, Ill.,

At the time the census was conducted by W. P. A., there were 3,017 persons living in Ziegler; 774 of them were engaged in private employment, either in the service industries or in mines; 269 were on W. P. A., N. Y. A., or in C. C. C. camps; 107 were without any work of any description. Thus a total of one-third of all Ziegler workers were without private employment during the census week. These figures show unemployment in one of the most active coal towns in Illinois during the peak of the year's activity.

In West Virginia the district north of Morgantown (Scott's Run) and the southern part of the State in Logan County are perhaps even more desperately hit. A special report was prepared by the National Research Project of the W. P. A. describing the plight brought by the machines which was so shocking that the report was not published,

In Pennsylvania, both central Pennsylvania coal fields and the anthracite region offer many similar examples.

With only 25 percent of the underground coal loaded mechanically, and with the immediate possibility of using labor-saving equipment in mines, the mechanization of loading has not yet gone halfway. Considering that in 1935 only thirteen and a fraction percent of coal tonnage was mechanically loaded and in 1939 25 percent was so loaded, we may expect within the next 4 or 5 years to double the mechanical tonnage. This would throw out of employment within the next few years at least 80,000 more miners.

This estimate takes into account merely the existing state of technique and projects it into the future. Yet we are reasonably sure that further steps in technology will be of even more drastic nature. Recent reports indicate the successful operation of coal mines on a wholly different basis. In Russia, for example, we are informed that some mines are sealed and set afire, which is maintained by a regulated supply of air and steam to produce "water gas" underground. This gas is then cooled and purified in the scrubbers and piped to distant points of consumption, at a cost said to be one-fourth the cost of gas generated from mined coal. Such a process requires a very small crew of gas workers and mechanics on the surface, virtually eliminating all mine labor as such.

I don't know whether I should proceed with the conclusion; if we have time I will.

Dr. ANDERSON. I have one more witness.

Acting Chairman KING. It will be in the record, and we thank you for your appearance. May I ask just what particular field you occupy in connection with the mining operations, mechanical engineer or electrostatics or what? What field do you cover?

Mr. POLAKOV. The engineering department is a new venture with the United Mine Workers, and in the first few years of its existence we handled all sorts of problems. We started with the study of mechanization in connection with the operating agreement that the United Mine Workers will study that jointly with the operators. Since the operators, however, have shown no inclination to cooperate with us for the last 2½ years, we have been doing that work exclusively ourselves.

Besides that, the function of the engineering department covers economic and statistical matters of production, cost of living, accidents, safety engineering, and a number of allied functions of that type.

Acting Chairman KING. And you have charge of that activity in the organization with which you are affiliated?

Mr. POLAKOV. Yes. I should like to introduce my remaining charts as exhibits.

(The charts referred to were marked "Exhibits Nos. 2741 to 2747" and are included in the appendix on pp. 17558-17564. Exhibit No. 2748 is on file with the committee.)

Dr. ANDERSON. The final witness for the morning session is Prof. Caroline Ware, associate professor of social history and social economy, American University, and chairman of social studies, American Association of University Women.

She is here to testify on a twofold aspect of our problem, which she has stated is a problem of effective participation as a producer and as

a consumer. Dr. Ware is an expert in the field of consumer education and labor studies.

Acting Chairman KING. Do you solemnly swear the evidence you are about to give in this hearing shall be the truth, the whole truth, and nothing but the truth, so help you God?

Miss WARE. I do.

TESTIMONY OF DR. CAROLINE F. WARE, ASSOCIATE PROFESSOR OF SOCIAL HISTORY AND SOCIAL ECONOMY, AMERICAN UNIVERSITY, WASHINGTON, D. C.

Dr. ANDERSON. State your name and address, please.

Dr. WARE. My name is Caroline F. Ware, and my residence is Vienna, Va.

Dr. ANDERSON. Dr. Ware, what is your professional position at the present time?

Dr. WARE. I am associate professor of social economy and social history at the American University graduate school in Washington.

Dr. ANDERSON. In your connection as chairman of social studies, of the American Association of University Women, what has been your duty?

Dr. WARE. My duty in the association has been to act as chairman of the committee which prepares material and responds to requests from study groups and the branches in the field of consumer education and other related subjects.

Dr. ANDERSON. How large an association is that?

Dr. WARE. Sixty-seven thousand members.

Dr. ANDERSON. Scattered over the United States?

Dr. WARE. Scattered over every State in the Union, and the consumer study groups are in 300 different communities. There are in all 870 branch groups in the organization.

Dr. ANDERSON. Studying consumers' problems?

Dr. WARE. Three hundred out of the 870 have been studying consumers' problems.

Dr. ANDERSON. And the others studying social problems?

Dr. WARE. Studying various problems; social, welfare, labor standards, and general economic problems.

Dr. ANDERSON. I understand you prepared a statement for the record. Do you wish to talk from it, or do you wish to read it?

Dr. WARE. I have a very brief statement that I would rather talk from than to read. What I have to say is chiefly this, The American system of public education was, as we all know, established on the assumption that in order to have an effective democracy it was necessary to have an educated citizenry. That system was established many years ago. The problem which led to the establishment of public education is with us today in the specific form, "How can we have a democratic citizenry in a technological society?"

As I understand the essence of a democratic citizenry, it is a citizenry whose members are competent to participate in the affairs which relate to their own problems in their own daily lives. That means that for us, for the people in our technological society, the problem is, How, through education and through other means can we develop the ability to participate effectively in the economic activities which are real to all our citizens.

Technology itself has determined the form in which we must answer that question, because the technology itself has, you might say, driven a wedge between the producer activities of the individual and the consumer activities of the individual. We no longer produce, most of us, most of the things which we consume; we produce for somebody else to consume; we consume what somebody else has produced, and it is this very fact of technology which you are discussing which has produced that situation.

Now, since technology has divided our individual economic activities into these parts, the problem of effective economic citizenship is a twofold problem of effective participation, as a producer and as a consumer. I would like to discuss the subject of adult education for economic citizenship under the two general heads of workers' education and consumer education.

I am making certain assumptions. First, I think I have already made clear the assumption of the continuing validity of the democratic premise.

Secondly, I am assuming that insofar as our economic system depends upon the bargaining relationship, whether between employer and employee or between producer and consumer, the parties to the bargain have to be equipped to bargain if the bargaining relationship is to be a real one.

Thirdly, I am assuming that, insofar as we have an economy which relies upon administrative action on the kind of decisions which are made when machinery is introduced, for example. Many such decisions are administrative decisions rather than buying decisions. In order to function as economic adults and to participate in bargaining and in administration, individuals need to have an understanding of the economic system of which they are a part, and particularly an understanding which is directly associated with their own economic function.

They need to understand the industry in which they work, and the factors affecting the goods which they buy. Moreover, as the extension of the technological society has brought more and more activity into the realm of public activity through the provision of public service and the intervention of Government to adjust and to regulate, it has become necessary for these same individuals to understand governmental activity relating to their lives. But it is not enough for individuals in our technological society to understand the economy and the Government. They must have the necessary tools with which to participate actively, if the principles of democracy are to obtain today.

(Mr. O'Connell assumed the chair.)

Dr. ANDERSON. Are you willing to be interrupted?

Dr. WARE. Yes, indeed.

Dr. ANDERSON. What do you mean by the generalization "by understanding the economy"?

Dr. WARE. I mean, specifically, that as lies within his power, the individual should understand the meaning of the economic activity in which he is engaged; he should understand his relation to the parts of the economy which he touches as a worker and as a consumer.

Dr. ANDERSON. Should that be specific understanding in the sense that he knows what the nature would be, for example, of a labor negotiation. Should a person who is affected by such a negotiation be able to read and interpret such negotiations?

Dr. WARE. Certainly. I am assuming that the things which are of direct bearing on his own economic life demand his understanding in just the way that things which have a direct bearing on his political life demand understanding.

Dr. ANDERSON. Do we have the facilities for such training and equipping of individuals?

WORKERS' EDUCATION

Dr. WARE. That is one of the things which we are beginning to develop through the field of workers' education. Workers' education is young in this country as compared with other forms of education. It has developed during the past 20 years, first from very small and privately sponsored beginnings, through the development of education within unions and through the extension of the services of the Federal Government, by the workers' education specialists in the W. P. A., and to workers who are seeking such an understanding.

If a worker is not merely an adjunct or temporary substitute for a machine, he must know not only his job on the line, but the plant and the industry of which he is a part. In one part of the rayon industry, for example, the union organization duplicates management from top to bottom. Opposite each subforeman, each foreman, each superintendent of the room or building or the plant or the company, there is a worker chairman of the same group; a worker chairman of the same group needs to know as much as management at that point in organization.

A very interesting illustration of what this can mean came out recently in a steel community in Pennsylvania, where the steel union was conducting a 2-month training course for union officers. In one community the classes were so good that the foreman who had to deal with these trained union stewards are reported to have stormed the class and demanded to be allowed to take part in it, too.¹

The International Ladies Garment Workers, at its 1937 convention, resolved that I. "An applicant for a paid office in the I. L. G. W. U. who has not previously served, shall not be qualified to run as a candidate unless he or she shall first have completed a satisfactory course of training conducted or approved by the educational department of the I. L. G. W. U., in localities where such courses are available." The kinds of things which were included in those courses of training are: 1. Background of theoretical courses in (1) History of the I. L. G. W. U. and (2) Economics of the Garment Industry; II. Practical Training Courses in (1) Parliamentary Procedure, (2) Trade Union Technics, and (3) I. L. G. W. U. structure and function.² Two years after this rule in the union went into effect the union's educational director reported that more students than could be handled had enrolled for these courses.³

Mr. MAGINNIS. May I interrupt you? I would just like to ask you one question. I don't quite understand your statement there in the rayon industry.

Dr. WARE. I had reference to the union organization in the viscose plants, the rayon workers union. In those plants the union organiza-

¹ Alice Hanson, Workers' Education on the March, *American Teacher*, April 1939, p. 2. (Dr. Ware's footnote.)

² *Justice*, March 5, 1938. (Dr. Ware's footnote.)

³ Hanson, *op. cit.*, p. 2 (Dr. Ware's footnote.)

tion down through the plant is so set up that for every representative of management there is a corresponding chairman, a shop chairman, for the union.

Mr. MAGINNIS. Is that corresponding or shop chairman, as you call it, working along with the other one?

Dr. WARE. He is a worker in the shop.

Mr. MAGINNIS. Do you mean there is an additional representative of the union working alongside the regular employee, whether he is a foreman or shop foreman or superintendent?

Dr. WARE. No, I just mean that if a foreman has a group of, let us say, a hundred workers under him, those hundred workers have a worker chairman in the union; if a superintendent has 500 workers, including the 100 under the foreman, there is a chairman of that 500; if there is a squad of 10, 15, or 20 men, with a subforeman, then there is a worker chairman of that same group.

Mr. MAGINNIS. And in that squad, that particular set of employees, they elect their chairman?

Dr. WARE. Yes, that is right.

Dr. ANDERSON. I take it the W. P. A. Workers Education program stems from earlier beginnings with the unions themselves and other private efforts?

Dr. WARE. Yes.

Dr. ANDERSON. It has taken on such proportions now, and has been in existence long enough, so that we may hazard a guess as to its future. Would you say that it had proved its worth to management and workers both, to make it look like a permanent institution, necessary in this complex economic situation in which we find ourselves?

Dr. WARE. My own answer would be very definitely yes. May I read an excerpt from a recent report of the Workers' Education Specialist of some of the demands from workers for the services of the W. P. A. Workers' Education Service. This is a report by Hilda Smith, the director, of one evening on a field trip in which she met with rubber and automobile workers in a midwestern town. I don't know the town. She asked them what kind of classes they wanted, and they asked, among others, these things:

Something to explain Social Security and how these new laws worked; classes on consumers' problems for the wives of union members in the newly organized women's auxiliaries; a teacher to talk about hygiene and the care of children; more help with English in the classes in parliamentary law and public speaking; advice from a librarian who knew which books and pamphlets would be most useful in a small library built up by one of the local unions; a motion-picture projector so that pictures might be shown before or after a union meeting or on a holiday.

Then what about someone to help with the newly organized sports league in one of these locals? Here as in many other places, the shorter workday in industry and the beginning of paid vacations had brought a new interest in recreation of all kinds. Could someone go along on their fishing trips, asked one young man, and teach "biology and all that wildlife stuff." Orchestras, choruses, drama groups, were mentioned and briefly discussed. There was no lack of interest in the fields of music and art, if only leaders could be found who understood not only music and art, but also how to use them in workers' groups.

Some union had made a survey of changes in their own industries; the displacement of men by new machines, accident rates, changing wage scales. Figures had been collected, but only a few people understood them. Could they get some help in making charts to show clearly and simply the results of these industrial studies? Maybe then their members would understand what the figures said and be able to use them in discussions of contracts or proposed legislation. Social science workshops, they had heard, had been started in other places. "What about one here?" these union leaders asked.

Miss Smith's comment on this report is:

That meeting with its suggestions of new needs and new directions for workers' education could easily have taken place in almost any industrial center in our country today, and in many rural districts also.¹

Colonel CHANTLAND. Miss Ware, is what you are trying to develop here or are developing a sort of postgraduate vocational education divided into two broad parts: First, to let each one learn more of his individual position and knowledge of the trends and effects, and, second, the specialized part of it which puts the certain number of better qualified ones up farther in the scale so that he can stand opposite his identical man from the other side in the industry? Is that something of the nature of it?

Dr. WARE. The word which I would have to be sure I was using the same way that you were is the word "vocational."

Colonel CHANTLAND. I am accepting it as it has generally been used in the discussions here, vocational education, that is the elementary training in a trade.

Dr. WARE. I am not talking about training in a trade.

Colonel CHANTLAND. I know you aren't; that is what I am trying to find out. Are you talking about something that would be in the nature of a postgraduate course following that? You assume that back of what you start with, don't you?

Dr. WARE. I assume a worker on the job, whatever his previous training; a consumer with a market basket, whatever her previous experience. With that as a starting point, I am talking about a form of adult education which builds upon the direct experience on the job and the market basket, and from that goes to and attempts to develop in individuals an understanding of their activity and an ability to function more effectively in their whole body of economic relationship.

Colonel CHANTLAND. Pick him up as a trade man, as a journeyman rather than an apprentice, and start from there?

Dr. WARE. You pick him up where you find him. You may find him with no formal education at all, or you may find him with school or college education back of it, but you pick him up on the job and go from there to the question of his desire to understand the job.

Perhaps if I quote from the President's Advisory Committee on Education the definition of workers' education as they see it, it will make it clear.

Colonel CHANTLAND. No doubt.

Dr. WARE. I hope it will make it clear. The President's Advisory Committee on Education, commenting on this program of the W. P. A., says:

Workers' education is an attempt to satisfy the individual's expressed desire to understand the problems of the working-wage class or group to which he feels that he belongs, to comprehend the relationship and responsibilities of that group to the rest of society, and, so far as possible, to apply the intellectual comprehension and emotional attitudes thus engendered to the process of living.²

Colonel CHANTLAND. That is pretty general, but you added something more specific to that when you had these more highly capable people as standing opposite—able to meet with and talk with their

¹ Smith, Hilda W. "New Directions for Workers' Education." *Journal of Adult Education*. April 1940, pp. 162-163. (Dr. Ware's footnote.)

² Campbell, D. S. Blair, F. H., and Harvey, O. L. *Educational Activities of the Works Progress Administration*. The Advisory Committee on Education, No. 14, Washington, 1939, p. 91. (Dr. Ware's footnote.)

parallels in industry. That is beyond this. It may be in there generally, but I thought you carried it specifically further.

Dr. WARE. I think this second definition carries it further still. The first definition which I read was from the person who surveyed the field. The second definition is from Miss Smith, the Workers' Education Specialist, and here is what she says: "Workers' education is a program offering to industrial, office, store, domestic, and agricultural workers an opportunity to train themselves in clear thinking through the study of those questions closely related to their daily lives as workers and as citizens," and then later she says, "Workers' education leads straight from the classroom to the community, encouraging the student to analyze his own situation as a worker and as a member of that community; to follow the classroom's term with further study of industrial and social problems; and on the basis of new facts discovered to assume definite responsibilities."¹ Carrying through to participation in a responsible manner is of the essence of the kind of education which I am talking about.

HEALTH PROGRAM ARISING OUT OF WORKERS' EDUCATION

Dr. WARE. I don't want to take the committee's time for illustration, but I would like either to give an illustration or to insert it in the record, whichever the committee wishes. The illustration is of a group of workers (this illustration again happens to be from the rayon industry) who went into the problem of health in that industry, and before they got through they touched the whole community, the Department of Labor had come in with a study, the compensation laws were involved, and the workers in the next State were trying to get a comparable law. Shall I introduce this in the record?

Acting Chairman O'CONNELL. Why don't you just tell us about it?

Dr. WARE. The story was this.² When the union was organized in the viscose industry, the union had a hard time finding in some of the rooms, workers with enough vitality and enough concentration, enough energy, to assume even shop steward jobs. They began to inquire as to whether maybe there wasn't something seriously wrong there.

There are two serious poisons, carbon disulphide poison, to which workers in the churn rooms are subjected in the regular course of their work, and hydrogen sulphide poisoning to which the spinners are subjected. In spite of these dangerous occupational disease hazards, almost no information on these poisons was available in American medical scientific or industrial journals when the union started organizing the rayon workers in 1937.

Acting Chairman O'CONNELL. I take it the management had no adequate information on these diseases?

Dr. WARE. Apparently not. There is some difference in the practice among the rayon companies with respect to health protection, and I am not fully informed. I can only give you this story here.

The union then set out to demonstrate the need for a study of the health conditions in the rayon industry. They set-up a health com-

¹ Smith, Hilda W. "Workers' Education at Determining Social Control." *Annals of the American Academy of Political and Social Science*. November 1935; pp. 82-92. (Dr. Ware's footnote.)

² Hanson, Alice. "Health Committees in Rayon," in *Workers' Education Through Action*. Affiliated Schools for Workers, February 1939, pp. 24-26. (Dr. Ware's footnote.)

mittee. They surveyed the plant conditions to try to make a systematic report on all cases of sickness, and they had an expert criticize their questionnaire. They had reported to their committee all cases of illness which developed, and they began getting not only occupational illness but accidents, until they got a basis for checking not only on illness, but on compensation cases and the proper handling of accidents.

As information about this survey went out into the shops, the workers began to come into the union office for information, and the health committee had to go out and find doctors and lawyers who would advise the committee and the patients about their cases and about their probable claims. After this activity had been going on for several months the United States Department of Labor requested the Pennsylvania Department of Labor to cooperate on a study of health hazards in the rayon industry. When they undertook the study, it was, of course, carried on by experts, but the union group cooperated in bringing cases before the experts that were making the study.

While the study was in progress, various community developments occurred. The Governor of the State mentioned the preliminary studies in a speech and brought the wrath of several chambers of commerce down upon his head. One newspaper offered as refutation of the studies finding a front page statement that "after all, we have the mute evidence of healthy workers walking the streets of Chester. This study after this can't be true."

Mr. MAGINNIS. Do I understand that management had nothing whatever to do with trying to meet that danger in the industry, that it was entirely the unions and the Department of Labor?

Dr. WARE. This sorry is entirely the story growing out of the union.

Mr. MAGINNIS. I understand that, but didn't management have anything to do with that?

Dr. WARE. No.

Mr. MAGINNIS. They didn't make any effort to try to protect their employees?

Dr. WARE. I can't answer that categorically without more information than I now have. As I understand it, the answer to your question is "No." As I understand it, whereas certain of the companies making some of these same things had acknowledged the presence of health hazards and had established conditions within the plant to try to deal with them—

Mr. MAGINNIS (interposing). In some of the companies the management were trying to deal with the problem.

Dr. WARE. That is right.

Mr. MAGINNIS. Then you couldn't say categorically the management had nothing to do with it.

Dr. WARE. No; I was talking of this specific situation, in a specific company.

Mr. MAGINNIS. You are dealing from the union angle entirely and you don't pretend to answer for what management has done or attempted to do to meet this situation.

Dr. WARE. I don't know the answer to that. I know only that when the study was undertaken it was not possible to find technical information.

Dr. KREPS. Miss Ware, I may say, as one who has studied the chemical industry, there are, of course, certain well-known poisons, and management is the first to try to see to it that the workers are protected. On the other hand, there are a number of chemicals concerning which the physical effects are not well known. We have had experiences with that in the administration of the Food and Drug Act. That sort of debate also takes place in industry, and there is a predisposition, a perfectly natural predisposition, in such a controversy for management to say, "Well, let's see; show us." There is such a thing as mere complaint on the part of the worker, and there is such a thing as management's resistance to action on every complaint by the worker. Now, the case that you mentioned is not, as might seem, an isolated one. I could demonstrate it in industry after industry. It is quite characteristic in this debatable area.

Dr. WARE. Thank you, Mr. Kreps.

Mr. PIKE. I have one along that same line. I was in a mine in Canada 7 or 8 years where they had been troubled with silicosis and knew they had trouble with silicosis for years. I asked the manager in what part of the mine people worked who contracted silicosis, and after many years' experience he didn't know. It never occurred to him to find out whether they got silicosis in the mills, at the faces, at the haulage levels, or where. I think within 6 weeks he had a pretty good answer as to where it came from. That elementary thing had never occurred to him.

Dr. WARE. That sort of thing comes out in these workers' classes all the time. For instance, in a class that I was teaching at one time there were some garment workers and the girls from a particular room said, "The light in our room is placed in such a way that it reflects from the metal plate on our sewing machine into our eyes, and girls that have worked in that room for even a relatively short time get so they just cannot see on the job," and all the workers in the room knew it, but that particular piece of information didn't get up through management. There are countless things like this of minor and major importance—this rayon story happened to be one of major importance.

Dr. KREPS. I may be anticipating what you want to say later, but aren't you pointing out that here is an example where workers' education, by changing the basis of dealing with management from assertion to fact, tends to raise the whole level of worker participation in industrial citizenship—a level, incidentally, that in the economic sphere is one we ought to reach quickly in this country? I was going to ask you whether a good many of our problems in the industrial-relations field have not been due to lack of experience on the part of worker leadership, experience which they can only gain either by long operation in the trade or some process of worker education. I would go further and ask whether probably some of the pressure for higher rates might not be abated, as it has been in Sweden, I believe, (I take it you are going to mention Sweden a little later), and that the workers themselves see that the way toward full employment and toward the highest annual earnings is not necessarily through higher wage rates. It seems to me all of this can only be attained through a vigorous program of adult worker education.

Dr. WARE. Yes. The main point which I would make would be roughly what you have been saying there; that is, that the area of worker participation, if we are to have a democratic society and at

the same time a technological society, must involve the economic and the public sphere. It goes way beyond a mere bargaining over a specific wage rate, as you have said.

Mr. HINCHES. Coming back just a moment from exactly that point to what you were saying with reference to health, as I understand it you didn't mean to imply that the employer doesn't likewise have a function to perform, you didn't mean to say that in many instances he doesn't have a very vital concern in the production of health hazards. All that you were saying was that in this field of health and accident there is at the present time a high hazard to workers, part of which may be inevitable, but which can always be somewhat reduced by increased knowledge of the source of the hazard, increased knowledge as to the means by which the hazard can be eliminated, and the willingness to make the necessary expenditures to reduce the hazard that is involved, and given that hazard rate which does exist and our ignorance with reference to the source of the hazard, and our unwillingness at times, and inability at other times, to make the expenditures that are necessary to completely eliminate the hazard, there is certainly a field in which the worker has at least as vital a concern as the employer in actively participating, pushing to a situation in which lower hazards occur. That is what you were driving at.

Dr. WARE. Yes; very definitely. This particular story that I started to tell included the community education by the workers, who got a reprint of an article which appeared in a medical journal and got it distributed to all the doctors in the county, the problem being on a frontier of knowledge; an occupational disease law went into effect in Pennsylvania, and the problem then became one of preparing compensation cases, and the workers participated there. The rayon workers in the neighboring State of West Virginia, where there was no such law, studied the Pennsylvania law and the experience of the workers in Pennsylvania and started in West Virginia to work for the same kind of protection. I want to use it as an illustration of the way in which a specific problem in a specific plant—namely, the inability of the union to find sufficiently vigorous workers in a particular room to take a union job of shop steward—led out through this whole range of contact in the community and made for more adequate participation.

May I add just one more quotation, this from the educational director of the particular union from which I have taken this illustration, who says:

An active union today is no longer an isolated business unit concerned only with the settlement of grievances in the plant. The fact that the new unions so largely are made up of unskilled and semiskilled workers means that earnings in this group will not for a long time to come represent an income to sustain a good standard of health and decency. Supplemental income must appear in the form of public services—housing, unemployment, old-age and health insurance, extension of public-school facilities, and services.

The worker's dollar, moreover, must be stretched in its buying power through cooperatives, through price regulation, and through credit unions for handling loans and savings. It is the business of the union in protecting its members and increasing their access to the good life to foster all these public programs which are directed toward more adequately feeding, clothing, housing, schooling, and doctoring the underprivileged two-thirds of the Nation.¹

¹ "Workers' Education Through Action," Affiliated School for Workers, February 1939, p. 5. (Dr. Ware's footnote.)

Did you want me to turn to Sweden and draw on the experience there?

Dr. KREPS. You traveled there this last summer, didn't you?

WORKERS' EDUCATION IN SWEDEN

Dr. WARE. Yes. I traveled there this last summer and I visited the center of the Workers' Education, the Trade Union College at Brunnsvik, and visited classes there and talked with the head of the Workers' Education Association as well as the head of the school. In Sweden workers' education is spread throughout the country under the general direction of the Workers' Education Association, which supplies materials and lectures and advisory services. Nearly one-third of the entire adult population of Sweden is included in the membership of organizations which support the Workers' Education Association there in Sweden. In addition, this work receives extensive public support, supplemental to the support which comes from member organizations, and that support is both local public and national public support.¹

The most intensive and ambitious part of the program is this Trade Union College which meets for 3 months during the summer. There some 50 young trade-unionists assemble for a 3-month course. They are rank-and-filers, picked by their unions and representing their unions; they are expected by their fellows to be the future leaders who will assume responsible positions.

Their method of study is very interesting, and may I take your time just to describe it? They want the very best in education, they can't afford to keep the best economists in Sweden at the school for all summer, so they bring one of the ablest economists in Sweden there for the first 2 or 3 weeks and he gives a series of lectures; then he goes away and leaves a tutor behind him, and divides the workers up into groups to write reports on a series of topics. Those reports are mimeographed and put in the hands of the entire school. The professor then comes back at the end of the summer and holds seminar discussions on these reports.

May I read you the list of some of the subjects on which they were writing reports:²

Population Developments in the Labor Market.

Women in the Labor Market.

Working Hours, Intensity of Work, and Unemployment.

The Effect of International Economic Relations Upon the Structure of Price and Production.

Planning Public Works from the Point of View of the Business Cycle.

Regional Differences in Wages and Living Costs.

Housing from the Social Point of View and the View of Production.

Rationalization.

Possibilities of Smoothing Out the Business Cycle.

Should the State Set Minimum Wages?

¹ Eleanor G. Colt, *Government Support of Workers' Education*, pp. 20-24. (Dr. Ware's footnote.)

² Landsorganisationens Skola. *Förvaltningsnämndens Bekättelse*. Stockholm, 1939, pp. 7, 8; class materials, summer 1939.

Should the Trade-Union Workers Movement Become Further Centralized? If So, in What Manner?

Should There Be a Leveling of Wages, and How Can Trade Unions Work for This?

These are the sorts of things on which those workers were preparing their own reports to constitute the basis of their seminar discussions, and, as I say, they were not now union leaders, they were rank and file, young people in their twenties.

Dr. ANDERSON. Dr. Ware, don't we have a growing experience in the United States on the same thing? I think I still am a member of the board of directors of the Western Summer School of Workers, and I have taught on its faculty several times. We have the same sort of thing there that you have just indicated in Sweden, although I suppose we are not nearly so far advanced as Sweden. The thing has taken hold here and it is moving very rapidly, is it not?

Dr. WARE. Yes; we have it, only Sweden has gone so much further.

I was interested in the comment of the head of the Workers' Education Association in Sweden on the character of this program. I commented on its broad scope and his answer was:

It must be so, for in Sweden labor has power and responsibility, responsibility which extends out to the whole community. The broad problems of the whole community must be understood by the leaders of labor. A strictly trade union college cannot confine itself strictly to union problems, for the problems of trade-unions are the problems of the economy.

That is Sweden's experience, which is way ahead of ours. It is along the line of democratic economic citizenship, looked at from the worker's point of view.

May I turn from the worker's approach to the consumer approach? Historically, the two approaches have come from different groups. Actually, in subject matter and in essential meaning they are very close together. Workers' education started with the worker in the industrial plant and has extended to white-collar workers and even professional workers, in the government, for example. Consumer education, or consciousness of the problems of economic citizenship of the consumer, has developed first in the middle-income groups; in such a group as the members of the American Association of University Women, in which I am active. The two are coming very close together as the workers are coming to see what goes out of the pay envelope is as important as what comes into it.

Workers' education and consumer education have in common not only that they are aimed at effective economic citizenship but they both start with concrete daily economic experience; consumer education starts with the market basket; workers' education starts in the shop.

The need for consumer education, as I have said, is a direct product of technology. It is a product partly of the splitting of functions through technology and partly of the complexity and multiplicity of goods which technology has put on the market.

In a nontechnological society, the problem of the consumer is to find the physical things or to make them himself. In a technological society the problem is to know and choose and have the means to acquire those things, and it is that that has made the new problem of consumer education a very real problem.

Consumer education started, as I say, with the market basket, and has grown out like circles from a pebble in a pool.

It started with attempts of consumers to learn to be good buyers, but very soon consumers found that the means of knowing enough about the things they were buying to be a good buyer weren't available, in many cases. Consumer education, like workers' education, leads out into an attempt to do something as well as to learn. Consumers found themselves seeking ways of getting more information on labels, in advertising, and in the hands of sales people. Then they found that there was difficulty even here, because although in many cases information was in the possession of the manufacturer and of the distributor, there were many cases in which there were no adequate terms to describe goods that could have meaning for consumers. So consumers found themselves asking, "How can relevant means of describing merchandise be developed; that is, how can standards for ultimate consumer goods be established?"

Mr. PIKE. The necessary translation of trade terms familiar in the industry but totally unfamiliar to the consumer?

Dr. WARE. That, for one thing, but that not alone.

Mr. PIKE. Going forward from that.

Dr. WARE. Going forward. Of course, no industrial consumer, no buyer of industrial products for further manufacture, would buy without specification, and the work of the American Standards Association over the years has developed a very extensive standardizing procedure for goods which go into further manufacture. Some of those standards are relevant or applicable to the finished product, and the problem there is to find ways of getting that information passed on to the consumer. Many finished products, however, have not had standards developed, so that the consumers found that the job was a job of developing standards as well as getting out the information which is now available.

Moreover, the kind of standard which is informative to the manufacturer who is putting things together may be quite different from the kind of standard which is relevant to the consumer; the consumer wants to know what use he can get out of it. He wants a performance standard, whereas the manufacturer who has technical knowledge wants a standard based on composition.

Mr. PIKE. That answers the question most completely. For example, say in cotton cloth, the manufacturers know that a certain given number of threads would mean a certain thing, but to the consumer that wouldn't mean anything in the world.

Dr. WARE. Consumers are beginning to learn about thread count. But consumers feel that they should have, let us say, A B C standards for sheets for a particular purpose which would give a basis of comparison. After all, a producer can be technically informed about a particular product, but the consumer's activity is scattered over so many products that consumers can't be expert in everything. It is that problem that consumer educators are trying to get over.

In my organization we had an interesting experience the other day. A man from a company came to us and said, "Here is our last example of glamor advertising." He had a magnificent book—it was a fabric firm—all full of pictures of these fabrics, done up with oriental scenes and Lord knows what—it must have cost a lot—and he said, "We are

through with that. Now we are going in for fact tags, and we want to know whether this is the right information to put on those tags." He had the results of a survey of consumer opinion—I don't know how carefully he had conducted it—showing a very, very cordial response to the kind of information that he was going to put on the fact tags. That is evidence of the process of consumer education which is going on.

Mr. PIKE. You might say the education was going the other way, too, perhaps.

Dr. WARE. That is true. Consumers trying to educate themselves found very quickly that the job couldn't be done by self-education unless the educated consumer moved out into action.

Mr. PIKE. And educated the manufacturer as to what they wanted.

Dr. WARE. Educated the manufacturer as to what they wanted and developed procedures for getting the relevant information in the right place.

I think perhaps if I just read over the list of some of the subjects which are covered in consumer education, starting from the problem in the market place, it has gone to the problems of consumer economic citizenship.

The General Federation of Women's Clubs, with some 3,000,000 members, has recently developed a series of what they call one-day programs in consumer education, and this is the brief list of their study leaflets:

Government Services to Consumers.

The Planning of Savings and Expenditures.

Our Taxes and What They Buy.

Interstate Trade Barriers.

Consumer Protection in Food, Drug, and Cosmetic Industries.

How Far Can Consumers Help Themselves by Cooperation?

Social Security.

Agricultural Production Control.

Medical Care.

Consumer Credit.

That is where consumer education, which starts with the market basket, leads; those are the questions which the General Federation of Women's Clubs has turned to.

The material which the American Association of University Women study groups are using along with their study guide on Scientific Consumer Purchasing¹ includes such things as this (I won't go through the whole list): Material on so-called fair-trade laws; credit to consumers; judging fabric quality, and other things of that sort; material on developing standards; food and drug regulation; the Federal Trade Commission, the complaint of the Commission in the case against Good Housekeeping magazine; interstate trade barriers; the methods which are now being carried out for cooperation between retailer and consumer; consumer taxes; the challenge of underconsumption. Those are just some of the subjects.²

The main contribution of consumer education, as I see it, is in the orientation which it gives to economic problems. After all, consumer education assumes that the consumer is a person and not just a market,

¹ Alice Edwards, Washington 1939. (Dr. Ware's footnote.)

² See also Consumer Education Service, News Letter, published by American Home Economics Association. (Dr. Ware's footnote.)

and assumes that the purpose of production is in order to have the things people need. Although that is a terribly obvious and self-evident point, nevertheless it is almost a new point of view, largely because we have developed a thoroughly producer-minded society.

A nice illustration of that is the story behind this publication of the Bureau of Home Economics on Children's Body Measurements for Sizing Garments and Apparel. When a project to get more standardization of sizes for children's garments came up, the question was, Shall the standards be set in terms of the practice in the trade or in terms of the sizes of children? It took 2 or 3 years' battle to get the project finally set up in terms of the sizes of children instead of in terms of the practice in the trade.

One could illustrate endlessly the respects in which we have a producer-centered society, which goes on the assumption that somehow or other if the interests of the producer and the seller are taken care of, the interests of everybody as consumers will somehow come out all right.

Our habit of calling the balance of foreign trade favorable when we get rid of more goods rather than when we get more goods is just an illustration of something which goes through our whole society.

Acting Chairman O'CONNELL. One illustration was fair-trade laws?

Dr. WARE. Yes.

Acting Chairman O'CONNELL. Price fixing?

Dr. WARE. Yes. One need not multiply the illustrations, but they could be multiplied.

The possibilities of the consumer approach are endless. I was struck with the possibility in a meeting of teachers in the District of Columbia that I was attending the other day where the discussion centered on the community resources in relation to the schools. One of the men on the panel, after the discussion had gone on and had brought out various interesting possibilities, said: "Do any of you have any experience of any community which has set itself the problem of figuring out what it wants its young people graduating from high school to do and what it wants done in the community? The community is not going to let those youngsters starve. Have any of you any experience in a community which has thought through its wants and resources in that fashion?" Well, a pall of silence fell over the meeting. But it seems to me that there is the direction in which the consumer-education approach goes.

WORKERS' EDUCATION AND ECONOMICS LITERACY

Dr. WARE. In summary, I think I would say that the major contribution of both workers' education and consumer education to the development of economic citizenship lies in their method and approach rather than in the specific content of any part of their programs. Workers' education is built on the assumption that the worker as a human being takes precedence over the worker as a tool. Consumer education is built upon the assumption that the consumer as a human being takes precedence over the consumer as a market.

Traditionally we have assumed that democracy began in the political ward, not in the shop or the market place, and education for democracy has been built in those terms. To my way of thinking, worker and consumer education together provide a constructive educational approach to the problems of democracy in a technological society.

Dr. ANDERSON. You infer then that bargaining involves some equality—that a worker, for example, will know enough about the whole economic scene to be able to act on something like an equal basis with his manager or employer?

Dr. WARE. Well, we have a traditional economic theory which assumes that we get the right price, the right wage as the result of bargaining in the market. Insofar as we are relying on that kind of mechanism, I would say that we have got to have a bargain which is a bargain, and not a take-it-or-leave-it proposition.

Dr. ANDERSON. The bargaining itself implies equal bargaining power.

Dr. WARE. Yes.

Dr. ANDERSON. And would you then move in the direction of an educational procedure for workers in which very precise information would be in their hands? For example, would workers' education include such things not only as negotiation and necessary elements of negotiation, but the use of such an instrument as the strike and what the use of the strike means, what discipline is necessary to use it effectively, and when it should or should not be used? Is that part of workers' education?

Dr. WARE. Yes; just the same as the use of the ballot and the same as the use of any of the social tools. I think I could generalize the answer to your question in this way: One of the products of our technology is that we do things in groups; we don't do many things individually. Since we are doing things in groups, in order to be effective we have to know how to use group tools.

Dr. ANDERSON. In other words, you don't any longer put the strike in the same category as the supposed unmentionable social diseases we are now beginning to take a look at openly. You say that the way to proceed is to take serious cognizance of all these social tools, learn how to use them effectively, and you will raise the plane of bargaining and substantially reduce the friction points. Is that right?

Dr. WARE. That is right. You have just taken the strike as an illustration.

Dr. ANDERSON. Yes, that is all.

Dr. WARE. Of course, it is the last social tool to use, everybody, I think, would agree.

Dr. KREPS. In other words, as you see the problem of living with the machine and getting the benefits of the machine, it consists fundamentally in raising the level of worker and consumer literacy, economic literacy, rather than in trying to break so-called log jams by going around and suing a few people or trying to subsidize somebody or trying to tax somebody.

Dr. WARE. I wouldn't regard it as an either-or; I would regard it as a necessary "and" to any program which may be developed in any other area. I would not say that either workers' education, or consumer education, or a combination of them, was the answer to all the ills of our society; but I would say that if we are to operate a democratic society in the face of technology, no matter what other devices are used economic literacy has got to come along, too, and it has got to be the foundation.

Dr. KREPS. In other words, the ability to make economic adjustments and to use, as I understand the Swedish consumers have

used, their organized power to emancipate themselves from monopolies of various kinds—the ability of workers to restrain their own desire for higher wage rates because of the possible impact on the economy as a whole, that type of self-discipline which is necessary to civilize the machine comes into operation with the kind of worker and consumer education program which you have seen operative in Sweden.

Dr. WARE. Which I have seen operative in the United States more than I have in Sweden.

Dr. KREPS. And in the United States, I should say.

Dr. WARE. May I put as a footnote a little illustration from a class of Southern workers in which the question of technological unemployment was discussed?

This was a class of very limited literacy and very limited vocational experience, and it included both agricultural workers and industrial workers. The class started thinking about technological unemployment, and someone mentioned a cotton picker. One of the girls in the class said, "The cotton picker is going to be awful; it's going to put so many people out of a job."

There was an Arkansas sharecropper in the class, and I turned to her and said, "Will you describe cotton picking for us, Johnnie?"

And Johnnie described cotton picking, how heavy the bag was, and how all the youngsters were out working in the field picking cotton along with the adults. One of the industrial workers shook her head and said, "Gee! It sounds as if that cotton picker was going to put a lot of cotton pickers out of mighty poor jobs."

And another girl said, "Yeah, but a mighty poor job is better'n no job at all."

They all shook their heads over that, and then I said, "Well, suppose you were in a position yourself to decide how to use this machine. Suppose it was your machine." They thought about that for a while and one of them said, "You mean if the people that are working on the plantation had the machine and could use it instead of being put off by it, why then the kids wouldn't have to pick cotton; they could go to school."

I think it is a relevant illustration.

Acting Chairman O'CONNELL. Are there further questions?

(The witness, Dr. Ware, was excused.)

Acting Chairman O'CONNELL. We will recess until 2:30.

(Whereupon, at 12:55 o'clock, a recess was taken until 2:30 o'clock of the same day.)

AFTERNOON SESSION

The hearing resumed at 2:35 o'clock upon the expiration of the recess, Sumner T. Pike, Department of Commerce, presiding.

Dr. ANDERSON. Before I introduce the first witness, I should like to introduce as an exhibit the testimony of Thomas F. Burns, vice president of the United Rubber Workers, on technological unemployment and decentralization in the rubber industry. This statement would have been presented orally were it not for the shortness of the time.

Acting Chairman PIKE. It may be admitted.

(The document referred to was marked "Exhibit No. 2749" and is included in the appendix on pp. 17564-17577.)

Dr. ANDERSON. Mr. Chairman, two witnesses will summarize the case studies and their own observations on the effects of technology upon the employment of the national labor force. They are Mr. Corrington Gill, of the Work Projects Administration, and Dr. Isador Lubin, a member of your committee.

Mr. Gill is before you.

Acting Chairman PIKE. Do you solemnly swear that the testimony you are about to give in this proceeding shall be the truth, the whole truth, and nothing but the truth, so help you God?

Mr. GILL. I do.

Dr. ANDERSON. Mr. Gill is accompanied by Mr. David Weintraub, who is responsible for a great deal of the work that will be discussed.

Acting Chairman PIKE. Mr. Weintraub, do you solemnly swear that the testimony you will give in this proceeding shall be the truth, the whole truth, and nothing but the truth, so help you God?

Mr. WEINTRAUB. I do.

**TESTIMONY OF CORRINGTON GILL, ASSISTANT COMMISSIONER;
AND DAVID WEINTRAUB, WORK PROJECTS ADMINISTRATION,
WASHINGTON, D. C.**

Dr. ANDERSON. Mr. Gill, what is your position?

Mr. GILL. Assistant Commissioner of the Work Projects Administration.

Dr. ANDERSON. How long have you been employed in this field of activity?

Mr. GILL. In 1931 I became the economist and statistician for the Federal Employment Stabilization Board; in 1933, in the spring, I became Assistant Administrator of the Federal Emergency Relief Administration, and have been with W. P. A. since July 1, 1935.

Dr. ANDERSON. Prior to that were you engaged in a profession that is related to the field of your testimony?

Mr. GILL. Prior to that time I had done some 6 years of research work in the field of economics and business conditions. Prior to that I was in newspaper work here in Washington, covering the departments for financial news, and as business manager of the Washington Press Service.

Dr. ANDERSON. And you have published in this field?

Mr. GILL. One book and several articles.

Dr. ANDERSON. And the book is a recent publication, Wasted Manpower.

Mr. GILL. Wasted Manpower, published last September.

Dr. ANDERSON. In which you have covered a good bit of the topic that you are going to discuss today.

Mr. GILL. In a broader way. This is one phase of the broad subject.

When the Works Progress Administration was established in 1935 we had had 2 years of recovery. Industrial production was substantially above the low point of the depression; industrial employment, however, had not picked up nearly as rapidly; the unemployed numbered 10,000,000 to 11,000,000, or about a fifth of the Nation's manpower.

As a functioning part of the administration's program directed essentially toward recovery, the W. P. A. was vitally interested in the

prospects for reemployment of this labor force. Since technological advance was obviously one of the important factors which affected these reemployment prospects, we initiated a group of studies of the role that technology played in current unemployment problems and long-run employment trends. This was the origin of the National Research Project on Reemployment Opportunities and Recent Changes in Industrial Techniques.

The other day Mr. Kettering spoke here about the cooperative nature of industrial research. Since the W. P. A. was not the only organization which had an interest in these problems, we too sought and obtained the cooperation of other governmental and private agencies and of industry and labor. One series of the studies, for example, was conducted in cooperation with the Bureau of Labor Statistics; other studies were done in cooperation with the United States Bureau of Mines, the Railroad Retirement Board, the Department of Agriculture and various agricultural experiment stations, the Department of Commerce, the Social Security Board, the Bureau of Internal Revenue, the Federal Trade Commission, and the Tariff Commission. Among the nongovernmental agencies were the industrial research department of the Wharton School of Finance of the University of Pennsylvania, the National Bureau of Economic Research, and the employment stabilization research institute of the University of Minnesota. Throughout, in collecting information the project has also enjoyed the cooperation of industry, of labor, and of farmers.

We feel that the National Research Project, directed by David Weintraub, is currently contributing the greatest amount of information on this question of the role of technology in production, employment, and unemployment. Thus far more than 60 published reports have resulted from the project's work.

Dr. ANDERSON. In order to facilitate Mr. Gill's presentation, we would like to introduce his exhibits into the record, and will assign them numbers.

Acting Chairman PIKE. They may be received.

(The documents referred to were marked "Exhibits Nos. 2752 to 2783" and are included in the appendix on pp. 17577-17596.)

Mr. GILL. The reports have been widely distributed and the value of the findings is well shown by the frequency with which material from the project's reports has been used before this committee during the past 3 weeks.

The two main subjects which I should like to discuss before this committee are (1) the economic role which technological changes have played in recent years and (2) the impact of technological change on workers. I will discuss these subjects primarily from the viewpoint of an agency charged with the responsibility of caring for the able-bodied unemployed.

The decade that has just passed is unique in American economic history. It has been marked by the worst depression the country has ever known—a depression unparalleled both in severity and in persistence. At the end of the decade recovery is still far from providing normally full employment of the country's human and material resources.

Perhaps the best indication of how much worse the economic difficulties of the last 10 years have been than those of any previous period is afforded by a comparison with the so-called great depressions of the

1870's and 1890's. Production and employment are the most vital elements in economic well-being. Although it is only in comparatively recent years that employment figures have been gathered, reasonably satisfactory production data are available as far back as 1870. Indexes of general industrial production undoubtedly furnish the most satisfactory measures for a comparison of the course of the three depressions.

I should like to submit this chart for the record.

Dr. ANDERSON. It will be admitted.

(The chart referred to was marked "Exhibit No. 2750" and appears below.)

EXHIBIT No. 2750

Chart 1 INDUSTRIAL PRODUCTION DURING THREE DEPRESSION PERIODS
1872-1882, 1892-1902, AND 1929-1939

INDUSTRIAL RECOVERY AFTER DEPRESSION

Mr. GILL. This chart compares industrial production for the three decades—1872-82, 1892-1902, and 1929-39. The peak year of the preceding prosperity is in each case taken as the base. The unique character of the decade that has just passed is immediately evident. The differences in severity and length between the depression of the 1930's and the two earlier depressions is so great, in fact, as to suggest a difference in kind. From 1929 to 1932 industrial production declined by almost 50 percent, as compared with a maximum fall in the 1900's of 13 percent, and in the 1870's of 7 percent. The contrast in the three recovery periods is quite as striking. In 1939 production averaged somewhat below 1929. In each of the earlier periods it had far surpassed the previous prosperity peak; 1882 was 70 percent above 1872 and, 1902 was 55 percent above 1892.

Other indicators tell the same general story. No data exists on which to base a direct estimate of unemployment in either the seventies or nineties. However, some idea of the extent of unemployment in the earlier depressions can be formed from a study of production and labor-supply figures. The latter are available for census years; 1870, 1880, 1890, and 1900 were all generally prosperous years. Hence it is reasonable to assume that unemployment in each of them was at or near the practical minimum. The increase in labor supply can thus be taken as a rough measure of the increase in employment for the decades 1870-80 and 1890-1900.

I would like to submit the next chart.

Acting Chairman PIKE. It may be admitted.

(The chart referred to was marked "Exhibit No. 2751" and appears on p. 17224.)

Mr. GILL. This chart shows the trend of gainful workers, minus those attached to agriculture, for each of the three decades—1870-80, 1890-1900, and 1929-39. It also shows the course of industrial production in each of these periods. Many refinements for which the materials do not exist would, of course, be necessary before any detailed conclusions could be drawn. One central fact does, however, stand out clearly. The increase in the severity of the decline in industrial production in the 1930's was so great as to leave no room for doubt that unemployment must also have been considerably more severe than in earlier depressions.

These facts are unmistakably clear. In every important respect the depression of the 1930's has been far more severe and far more persistent than any previous depression the country has seen. In 1939 we had 2,000,000 or 3,000,000 fewer persons employed than in 1929, although the volume of goods and services produced was almost the same. This unemployment was in addition to the 2,000,000 persons who were unemployed in 1929, and was aggravated by the natural increase in population which resulted in over 6,000,000 net new additions to the labor market. Consequently, despite recent attempts of some newspaper columnists to write them off, there were 10,000,000 to 11,000,000 unemployed in 1939. The major problem is thus one of fuller utilization of the productive forces of the Nation—natural resources, plant capacity, and labor.

With respect to the subject matter of these hearings, the question arises: What were the effects of technological changes on recovery in recent years?

As your chairman aptly put it the other day: "The measure of technological advance is the capacity of the masses to buy the products

EXHIBIT No. 2751

Chart 2 INDUSTRIAL PRODUCTION AND THE LABOR SUPPLY DURING THREE DEPRESSION PERIODS

WPA 2442

of technology." We are therefore interested not only in the physical aspects of changing industrial technics, but also in the social and economic ways in which these technics are used.

Traditionally, technological progress has contributed to a continually expanding economy by stimulating increases of production

through the reduction of costs, by introducing new products and new industries, and by increasing the demand for capital goods. Hence, technological progress has, in the past, played an important role as a factor of recovery from depression.

Now, it has already been pointed out to you by several witnesses that technological changes in industry are continuous and cumulative in their effects. There is no way of telling what the technological changes of the future will be, or precisely how they will affect employment and investment. Moreover, it is important to realize that the consequences of technological advances are by no means uniform.

The automobile industry, which has been discussed before you at some length, is a classic example of a technological innovation that, in the past, had created more jobs than it destroyed and also provided important indirect support to employment through its effect on investment and income.

That such an effect of technological change is by no means universal can be seen by a glance at our industrial history since 1920. The country's manufacturing industries were, throughout that period, subject to continuous and cumulative technological changes. The effects of these changes on labor requirements are reflected in the measures of increased labor productivity which are embodied in several of the National Research Project's reports. Many of these data have already been presented to you by Dr. Kreps and others. These increases in labor productivity were, during the 1920's, usually accompanied by increases in production. But in the face of the rate at which technological improvements were taking place, the increases in production were not great enough. The manufacturing industries, although their production increased by 50 percent during the 1920's, showed virtually no increases in employment. Other industries which, prior to the World War, were relied on to provide an increasing number of jobs for our growing population not only failed to continue this traditional role but in many instances also failed to maintain their previous employment levels. Mining and the railroads registered substantial declines. Employment in agriculture declined during the war period and showed no increase during the twenties.

These increases in the productivity of labor represent continuations of past trends in our economy. The particular feature of recent developments is the important part played by a multitude of refinements and improvements, which are a day-to-day outgrowth of developing science and technology. The revolutionary changes which are associated with the initial shift of an industry from a handicraft to a mass-production basis pave the way for a continuous chain of less spectacular changes whose effects on labor productivity may be even more important. Revolutionary changes which result in the direct displacement of workers are by no means a thing of the past, as you heard in the description of the introduction of the continuous-strip mill by an earlier witness. Today, however, such changes rarely occur. The typical changes in industrial processes at the present time are the day-to-day improvements of already existing equipment; they are usually not spectacular and many of them require relatively small capital outlays.

Thus the development of tungsten carbide steel has made it possible to increase the operating speeds on machine tools as much as thirtyfold without any important additional capital outlay. Metal-

lurgists have also developed more easily machinable alloy steel which has enabled many manufacturers to increase the output per unit of labor time from 30 to 50 percent. The important part played by increased knowledge of chemical changes and its application to industrial processes is illustrated by the introduction of organic accelerators, which reduced the time for curing rubber tires by one-half to two-thirds, with only small attendant capital outlays. Thus, operating costs and labor requirements have been significantly reduced by a series of refinements which create small or no investment opportunities.

ADVANTAGE OF SIZE IN MECHANIZATION

Mr. GILL. Many of the improvements and refinements in machines are associated particularly with equipment of large capacity. Aside from improved design, size is frequently an advantage in and of itself. Large-capacity equipment frequently requires no greater operating labor per operating unit than smaller equipment. Furthermore, the cost of manufacturing a particular type of equipment does not usually increase proportionately as the capacity of the machine increases. Accordingly, the capital investment per unit of capacity usually decreases with an increase in the size of the equipment. In the petroleum-refining industry, for example, for one type of equipment, operating costs per unit of capacity for the large units are only about one-third as great as for the small units. Similarly, investment per unit of capacity is only about one-third as great for the large as for the small units. These economies of large-capacity equipment are available principally to the large enterprises. This is due both to the technical possibilities of large-scale production and to the availability of funds for investment.

Other types of technological change which accrue principally to large enterprises are the mechanization of handling and the introduction of continuous processes. The most important economies associated with these changes follow the reorganization of plant lay-out to assure the continuous flow of materials and the necessary synchronization of one operation with another, that is, by improvements in the organization of production—an important phase of recent technical advances. I should like to illustrate this by reference to the conveyor assembly-line system of production which has effected spectacular economies in such mass-production industries as automobile and radio manufacture, which involve the assembly of numerous parts. The elimination of handling labor by the conveyor is only a small part of the total economies effected. Labor productivity is increased, principally through the reduction in stoppages and the increased intensity of labor, whose speed is to a very large extent set by the speed at which the belt operates.

In large-scale industries working with homogeneous materials, the introduction of the continuous-process principle has effected equally great economies, but has been accomplished somewhat differently. Previously distinct operations have been integrated, either directly or through the use of mechanical conveying equipment. The necessary synchronization is accomplished largely with the aid of instruments, and much operating as well as handling and storage labor is eliminated. In many of these industries, notably electric power, petroleum

refining, steel, glass, paper and pulp, and chemicals, after two decades of such developments, entire departments and plants are now operated from central instrument panels at which a few operators are stationed.

Such recording and controlling instruments, employed in large, highly mechanized plants, are an example of the type of equipment, auxiliary to the principal production units, which has found extensive application in recent years. Such auxiliary devices have involved only small capital outlays in relation to the economies which they made possible.

Numerous instances could be cited to show the reduction in operating costs effected through the precise regulation of processes with the aid of such instruments. According to one of the project's studies, the expenditures for controlling and measuring instruments per \$1,000 of machinery rose from less than \$4 in 1919 to more than \$14 in 1939. The increase in the use of industrial instruments which automatically control the operation of machinery or processes has been especially notable.

As a percentage of total sales, controlling instruments have risen from 8 in 1923 to more than 35 at the present time.

Not only are the larger enterprises the principal beneficiaries of the typical developments in industrial techniques, but they also possess the organization for systematic technical advance, through organized industrial research. As one of the project's reports has shown, the number of workers engaged in industrial research has increased five-fold during the past 2 decades. It is estimated that in 1940 close to 30,000 research workers are employed.

This work has been concentrated in the hands of relatively few companies; half the research personnel is employed by about 50 large corporations. Approximately 2,000 other concerns employ the other half of research personnel, while more than 150,000 manufacturing companies do not maintain any organized research. In 9 leading industries, one-fourth of the companies that operated laboratories in 1938 employed between 56 and 90 percent of the research workers in the respective industries.

Now, there are certain points which I should like to stress with respect to the characteristics of recent technological developments.

First, the establishment of the basic machine techniques, which was accomplished in the bulk of manufacturing industries before 1920, has multiplied rather than restricted the opportunities for technological change. There is, therefore, no reason to expect any cessation in the rate of increase of labor productivity, since it can be expected that as mechanization continues fresh opportunities for improvement will unfold themselves.

Second, while revolutionary changes in technique are still occurring, the emphasis in the recent period has been on detailed improvements in established techniques. These latter changes are, however, extremely pervasive; in time they cut across the whole production processes of an industry, spread from industry to industry, and their cumulative effect on labor productivity and their threat to the security of workers has been far greater than the occasional, spectacular, revolutionary changes.

Third, it is important to note that technological advances may be reflected in a reduction in labor requirements outside of the establish-

ment in which they occur. Illustrative of this is the reduction in the demand for coal as a result of improvements in the efficiency with which coal is burned. One of the project's studies shows that fuel consumption per unit of output was reduced by almost 80 percent at central power stations between 1899 and 1936, by 32 percent on steam locomotives between 1917 and 1936, and by 16 percent at cement plants between 1914 and 1935. The difficulties of the coal miners are in no small degree ascribable to this technological development outside of their own industry.

Fourth, the nature of recent technological changes has been such that significant increases in labor productivity have been accomplished in many instances without important additions to capital investments. The studies of the National Research Project present a mass of information covering changes in technology and productivity during the last 2 decades or more. During the last decade the emphasis has been on technological changes of a labor-saving rather than plant-expansion character. This is reflected in the project's findings on recent types of changes and on productivity in mining, manufacturing, transportation, communication, and power production. Notwithstanding the fact that many factors operate to reduce productivity when production is curtailed, the findings show that productivity continued to increase in most industries even during the decline of the early thirties.

In many instances, old and fully depreciated machines are replaced by improved machines, which are capable of much higher outputs but which do not involve an increase in investment. The economies effected through the use of auxiliary equipment are frequently accomplished with only small capital outlays. In many cases, moreover, the smaller capital outlays involved in the use of auxiliary equipment are a substitute for the larger capital outlays involved in the construction or in the equipping of new plants for additional production capacity. Although the introduction of handling and conveying equipment involves considerable investment, there is frequently no increase in investment per unit of output since the initial outlays are offset by savings in space, the fuller utilization of equipment, and the reduction of raw-material inventories and storage.

The fifth point I want to make with respect to the characteristics of recent technological developments is that they are obtainable principally by the large concerns. There is evidence that in many industries the small concerns are being forced out of business because they cannot keep abreast of new technological developments. In testimony presented to you by an earlier witness, the elimination of many small steel mills was attributed to their inability to employ the new processes.

In the bulk of American industry, the trend toward the elimination of small enterprises and the concentration of production in large corporations is an observed fact. Our studies have shown that this trend has a technological basis in the advantages in production costs gained by the organization of production in large plants, by equipment of large capacity, and by many types of special-purpose equipment which aid in economies of production while they add little to capital requirements. The economic advantage possessed by large enterprises with respect to the utilization of labor has been reflected in most of the manufacturing industries studied by the project. In mining operations, also, the benefits of mechanization tend to accrue to the larger

enterprises, and mechanization in agriculture favors production on larger farm units.

One more point. The strengthening of large enterprises through technological changes has its basis not only in the characteristics of their production techniques, but also in the concentration of research. This concentration tends to widen the technical and economic advantages of large enterprises over smaller ones which are without research facilities and cannot keep pace with new scientific developments. This factor is important in any evaluation of the prospects for the development of new industries and new products, on a scale sufficiently great to constitute a demand for capital goods substantial enough to stimulate general recovery. In considering the prospects for the development of new industries out of current industrial research, it must be remembered that though the companies which finance this research are interested in the development of new products, they are also concerned with the safeguarding and improvement of their existing investment in plant and equipment.

I have earlier referred to recent types of technological changes which typically find application where production is organized on a large scale. This is doubtless in part ascribable to the fact that most research is done by large enterprises which naturally concentrate on their own problems. The characteristic technological advances which they develop cannot usually be applied in small enterprises either because finances are wanting, or because the techniques cannot be employed on the production scale of such enterprises. Yet this is not a necessary development in all industries. Efficient production does not necessarily exclude small-scale operation, provided the technological base is studied specifically with a view to improving it; I am certain that in some cases at least research can fruitfully be redirected to problems of the small enterprise.

Some means should be developed for making the results of scientific research more generally available to small as well as large enterprises. Greater emphasis should be given to industrial research directed toward the development of new products or industries and to those technical problems which are peculiar to the small and medium-size producers now without adequate research facilities. Such a development, encouraged and perhaps in part supported by government, may make it possible not only to employ all of our trained scientific personnel, but also to stimulate capital investment.

Up to this point I have sketched the economic role which technological change has played in recent years. I come now to the second subject, namely, the effects of technological changes on workers.

EFFECTS OF MECHANIZATION ON WORKERS

Mr. GILL. The process of industrial change is by its very nature accompanied by a constant displacement and reabsorption of labor. When new occupations, plants, and industries come into existence while old ones decline, when new areas become industrialized while old ones become "stranded," when a technological change results in the displacement of an old product or process by a new one, when job requirements are altered, when fewer workers are needed to meet the requirements of production, workers lose their jobs. Under these circumstances,

even when such changes are accompanied by an absolute increase in the total amount of employment offered, unemployment of individuals and groups of individuals is continually being created because of changes in the location of activity, transformations in the nature of the employment offered, or changes in the types of persons hired.

One of the most important factors in changing the location of economic activity has been the persistent relative decline of agriculture as an employer of our nation's labor. As the technique of production in agriculture has been steadily altered and improved, it has been possible to produce food and raw materials for a growing population and an expanding economy with an ever-dwindling proportion of the nation's workers. In 1870, for example, more than half the working population was engaged in agriculture. Today only one-fifth of the population is so engaged and a large share of this one-fifth is no longer necessary to produce the volume of agricultural products which we consume. One result of this marked decline in opportunities on the land has been the migration of approximately 2,000,000 persons annually from the land to the cities in search of industrial employment. Industry, however, even in the 1920's, was unable to absorb this tremendous extra supply of labor that was "released" from agriculture. This is reflected in the fact that the 1920's saw annually an average of 1,500,000 persons leave the cities to return to the land. That is to say, some 3,500,000 migrations took place annually in this country as a part of the search for jobs.

The accumulation of people unable to secure employment and unable to maintain themselves on the land is continuing. Although there has been some reduction in the amount of migration from the land, this slackening is not caused by a lessening of the problem conditions on the land, but by the development of severe depression conditions in the cities. As a result, there are uncounted persons dammed up on the land who in recent years would have moved to the cities had conditions there warranted the hope that they might find employment. These constitute an unemployed reserve for industry that has not even been tapped, and one which is growing steadily. The continuation of technological changes in agriculture impel them to move, but in the current industrial situation there is no place for them to go.

Another broad industrial change which has been constantly creating unemployed workers, even in periods of generally rising activity, is that which results in the transfer of the location of industrial activity. America is dotted with cities and towns which can point to better days when they were flourishing commercial or industrial centers. As methods of transportation and communication have changed, many a canal and river town lost its locational advantage. As automobiles, trucks, and improved roads made large cities more easily accessible, many a rural shopping and marketing center has lost most of its trade. Stranded towns abound in areas where once rich deposits of coal, or timber stands, or bonanzas of ore have been exhausted, or where industries have lost out in the competitive struggle with industries in other areas. Thousands of skilled textile workers have been left stranded in New England towns when mills either moved southward or went out of existence because of their inability to compete with southern manufacturers. Over 200,000 coal miners lost their jobs between 1923 and 1929, when 3,000 commercial coal mines closed down. The better utilization of coal and the increased use of other fuels cut into the

market, and what demand was left went to the technologically more advanced mines.

In a true sense the populations that are left behind represent a group stranded through the operation of industrial and technological change. Their situation represents a pressing phase of our general unemployment problem which will continue to exist, short of an extraordinary expansion of productive activity.

As examples in this connection I would like to refer to some studies made by the W. P. A. in various localities.

In 1935, the year in which the great Amoskeag Mills, of Manchester, N. H., were shut down, more than 17,000 different persons had had employment in these mills. After the shut-down, there were a few other jobs to which the displaced workers could turn. In a field survey conducted late in 1936, only two-fifths of the men and one-fifth of the women interviewed had had any work since their last Amoskeag job in 1935. Only one-third of the men and one-sixth of the women were employed at the time of the interview. Of the total man-months elapsed between the last Amoskeag job and October 1936, only 15 percent were spent in employment. Under these circumstances the need for relief became acute and continued to be so through the ensuing years. About one-fourth of Manchester families were receiving general assistance or W. P. A. work in 1937. In 1938 the average rose almost to 29 percent.

Somewhat similar situations prevail in several of the declining Massachusetts textile centers. New Bedford is a good example. It had 31 cotton-textile mills running in 1920, and employed 34,000 textile workers. While new plants in the South flourished, New Bedford had slipped backward. By 1937 the number of cotton mills had been cut to 17, and the 34,000 mill workers employed had shrunk to 14,000. Between 1937 and 1938 another 6,000 cotton-mill workers were thrown out of work. During the two decades since the World War, New Bedford cotton textiles have lost about four-fifths of their workers. In spite of some new industry, New Bedford is clearly a chronically depressed community. About a year ago, 30 percent of all the available workers were jobless. Among workers whose last job was in the cotton mills, 37 percent were unemployed, and their average duration of unemployment was a year and a half.

Brazil, Ind., presents a similarly drastic situation affecting a somewhat smaller population. As a result of the general decline of coal-mining operations in the region and the collapse of the clay-products industry in the early thirties, more than one-third of the employables in the community were unemployed in 1936. During the 3 years preceding 1936, the number of different persons who had received public assistance of some kind was equal to 71 percent of the 1930 population.

A block of counties in southern Illinois, where coal mining is the major industry, presents another clear-out example of a depressed area with a large stranded population. The decline of activity in these counties (Franklin, Saline, and Williamson) began well before 1929, and had, by 1939, reached the point where two-fifths to one-half the available labor force was without private employment.

The peak year of employment was in 1923, when 36,000 workers were employed in 105 shipping mines. By 1937 the number of these mines had declined to 40. With mechanization, the man-day output of the surviving mines had risen from 4.9 tons in 1923 to 8.8 tons in 1938,

and at the same time approximately 5,000 additional men were displaced. In all, mine abandonment and technological advances had reduced employment opportunities by about two-thirds—from 36,000 workers in 1923 to 12,500 in 1937.

The cumulative effects of these developments on the community are shown by an unemployment census conducted in these counties about a year ago. At that time approximately 42 percent of the total labor force was unemployed; and about three out of five unemployed workers were dependent upon the W. P. A.

(Senator O'Mahoney, the chairman, resumed the chair.)

The CHAIRMAN. Did you have any studies made in any of the other coal-producing areas of the country?

Mr. GILL. Yes, we did, Mr. Chairman. We made some in Pennsylvania and in West Virginia.

The CHAIRMAN. Were the results of all these investigations substantially the same?

Mr. GILL. Substantially the same. I believe that the Illinois situation was a little worse, but it was only a matter of degree. It was quite similar otherwise.

EFFECT OF MECHANIZATION ON SKILLS

Mr. GILL. With respect to changes in the nature of jobs as distinct from their location, there can be no doubt that technological changes markedly influence the quality of labor requirements. Whatever may be the trends in production and employment at any time, the first effects of changes in technics are the displacement of workers, changes in the kind of labor required, and, as Mr. Murray's human exhibit so tellingly illustrated the other day, the obsolescence of particular skills and occupations. These often result in the need for unemployment relief even though, eventually, there may be increased demand for another type of labor somewhere else. The effect has been different in different occupations. Technological changes have favored semi-skilled jobs at the expense of both the highly skilled and the unskilled workers. In many cases new skills must be learned. Frequently the new jobs are lower in the occupational scale. Often it is a matter of months and sometimes several years before reemployment takes place. For the older worker it frequently means permanent unemployment.

The National Research Project's studies have shown that the jobs of factory production workers are steadily becoming more simplified as machinery is made more automatic or more specialized and as production methods are otherwise improved by management. Where an entire process is rendered highly automatic and continuous, both unskilled and skilled workers are eliminated. On the other hand, where auxiliary devices, such as recording or controlling instruments, simplify the method of work by eliminating operations which formerly required long training and great dexterity, semiskilled labor may be substituted for highly skilled workers. This reduction in skill requirements is naturally a prime objective of management, since the wages of unskilled workers are lower than those of the skilled, and unit labor costs are consequently reduced by the change.

While stranded communities present a spectacular type of problem, due to the concentration and isolation of the unemployed group, our

studies have indicated that industrial changes which alter the nature or volume of demand for certain types of labor can create special groups of workers who are as effectively stranded in a highly diversified industrial community as those residing around the tipples of shut-down coal mines.

The textile industry provides examples of a number of such occupations. Weaving and loom fixing in the woolen and worsted, carpet and rug, and upholstery-goods industries require a high degree of skill which cannot be used in other industries. These occupations have been declining since the early 1920's as a result of the introduction of more automatic looms and also because of a decline in the demand for the product of these industries.

The CHAIRMAN. To what do you attribute that decline in demand?

Mr. GILL. Partly the use of linoleums and other new floor coverings. I think that would be a major example.

The CHAIRMAN. That is technological substitution.

Mr. GILL. It is a substitution.

The CHAIRMAN. It is a substitution because the manufacturing has been vastly improved.

Mr. GILL. Vastly improved, but it is a shift. A different group of individuals get work in the linoleum plant than those which were displaced in Philadelphia, let us say, in the field of carpet and rug manufacturing.

The CHAIRMAN. In other words, the displacement of labor isn't at all to be ascribed solely to improved looms, improved machinery, but frequently to substitute materials for those that were—

Mr. GILL (interposing). That is true in this case, I believe, sir.

In Philadelphia, the center of these branches of the textile industry, 29 percent of the weavers and loom fixers were unemployed in May 1936. One-fifth of these unemployed had lost their last regular jobs earlier in that year. Twenty-eight percent had lost their jobs the previous year, 1935, 13 percent in 1934, 12 percent in 1933, 7 percent in 1932, and 20 percent prior to 1932.

The CHAIRMAN. What is the base upon which these percentages are figured? Twenty-eight percent of what?

Mr. GILL. It is the number that were unemployed in May 1936, adding up to 100 percent.

That is, one-fifth had been unemployed continuously for more than 5 years.

A sample study of the work experience of a group of unemployed railroad workers indicates that there also, because of the limited transferability of their skill to other industries, displaced workers were able to find little work in other industries. Moreover, the longer the attachment to the railroad industry, the more difficult it was to find work outside of this industry. The proportion of workers finding other work during periods of interruption of railroad employment ranged between a high of 63 percent for those with less than 5 years' service to less than 10 percent for those with service records of 30 years and more. The factor of age is, of course, partially responsible for inability to find work in other industries; but long years of attachment to an industry coincide with advancing age. Thus, when such workers are displaced they are at a double disadvantage in finding work in other industries or occupations.

The effect of changing skill requirements as a result of mechanization is illustrated by our study of cigarmakers after the process was converted from a system employing hand workers to one utilizing machinery and machine operators. One of the major results is the fact that the skill of the hand cigarmaker is not needed at the new process, and women are generally substituted for men. In our study, 5 years after the lay-off, 13 percent of the men were self-employed cigarmakers, another 17 percent were employed by others in the cigar industry. Though many of them searched for work as cigarmakers, the majority did not find it, and 25 percent of them found no work at all during the 5 years.

With these and other economic factors constantly augmenting the labor reserve, the size of which has been swollen to tremendous proportions due to the long continuation of depression conditions, certain special problems have developed within the general unemployment problem. Because of their age, their sex, their race, their skill or lack of skill, the nature of their previous experience, or even because of the length of time they have been unemployed, certain workers face particular difficulties in securing jobs. In a labor market crowded with aspirants for whatever job openings arise, they are passed over in favor of other job seekers who appear to the employers more desirable.

INCREASED UNEMPLOYMENT AMONG YOUTH

Mr. GILL. One of the most tragic of such special problems is that of the youth entering a labor market already crowded with experienced unemployed. The young people on the farms face perhaps the most desperate situation. They are growing up in a situation where, with advancing technology, agriculture is unable to provide a livelihood even for those who were formerly associated with it. In the cities also, particularly where opportunity has been declining or stagnating, the youths unable to secure even a first job in industry have been a most important element in the general unemployment situation. In Philadelphia, for example, 7 percent of the total unemployed in 1933 were workers who had never secured a first job; by 1936 this proportion had reached 20 percent of the unemployed; and by 1937, 21 percent.

While it may be impossible to designate the unemployed youth of this country as technologically displaced, it is nevertheless true that our production activity has failed to keep pace with productivity advances, that in spite of production levels almost equal to those of 1929, there were no jobs for them in 1939, and that as a result this important group is losing valuable years in which it might be fruitfully employed and contributing to our economic life.

The CHAIRMAN. Does that condition which you just described represent the situation as it is to be found elsewhere in the country? The figures you have taken are those of Philadelphia. How widespread is this condition?

Mr. GILL. It is widespread; it is all over the country, Mr. Chairman. It just happens that we made a study of this particularly in Philadelphia. We have a good deal of other data available at W. P. A., however, which indicate that the problem of the unemployed youth is serious throughout the country.

The CHAIRMAN. It is perfectly appalling, that it could be said of any community that 21 percent of the unemployed were persons who

had never had a first job, and you think that that condition may be found elsewhere in the country?

Mr. GILL. It is found elsewhere. We find it in the W. P. A., in the youth that we have there. A very high percentage of the youth that are employed on the N. Y. A.—that is the National Youth Administration—have never had a job and have striven unsuccessfully for months and sometimes even for years to get one.

The CHAIRMAN. Well, does that not indicate to your mind that a primary and supreme necessity is that of finding a way to stimulate the creation of normal jobs?

Mr. GILL. It does, yes, sir.

The CHAIRMAN. Productive jobs?

Mr. GILL. Yes, sir.

The CHAIRMAN. Would it be proper for me to ask you whether you consider the jobs that are created by W. P. A. as the type of job that can offer an opportunity for a permanent cure, or by N. Y. A. either, for that matter?

Mr. GILL. May I come to that later, Senator?

The CHAIRMAN. Certainly.

Mr. GILL. It is in the statement.

The CHAIRMAN. I have been anticipating your paper.

Dr. ANDERSON. In 1933, 7 percent of the unemployed were people who had not had a first job in private industry, it moved up to 20 percent in 1936, and to 21 percent in 1937. Have we leveled off, then, at a point where about 20 percent of W. P. A. is made up of these youth?

Mr. GILL. Between 1933 and 1936 unemployment was reduced in Philadelphia as in other parts of the country. What happened was that those who got jobs were for the most part experienced workers, so that the people who had not yet held a first job became a larger proportion of the total unemployed. But these figures do not refer only to W. P. A. workers.

Dr. ANDERSON. Oh, I thought they were W. P. A.

Mr. GILL. No, they are unemployed people; some were on W. P. A. and some were not. They were not in private industry.

Dr. ANDERSON. In other words, they are relievers or nonrelievers?

Mr. GILL. No, they are unemployed people.

Dr. ANDERSON. Unemployed regardless of their condition?

Mr. GILL. That's right. Some were on direct relief, some were W. P. A., some were living on their savings; there were all types of unemployed in that group.

Dr. ANDERSON. And do you think that will be the census figure for 1940?

Mr. GILL. I wouldn't like to forecast, but this is a census of Philadelphia, a complete census of a 10 percent sample of the city, made up on a very careful basis. I don't know, of course, what the census of 1940 will show for the country.

Mr. O'CONNELL. Were these figures intended to include the unemployables or merely unemployed?

Mr. GILL. The definition is essentially the same as that used by the census. It excludes unemployables, but no physical examination, of course, was made.

Dr. ANDERSON. Do you know of any other such studies which would give us a measure of the condition elsewhere?

Mr. GILL. There was a census in Michigan in 1934 or 1935, and a census made in Massachusetts in 1934, I believe it was, had similar material in it.

Dr. ANDERSON. It came to about the same conclusion, as I remember it?

Mr. GILL. Just about the same conclusions. I haven't the data here. Other National Research Project studies also have showed substantially the same results.

Colonel CHANTLAND. Mr. Gill, did you say that some of these who had not had their first jobs were living on their savings?

Mr. GILL. No; I didn't mean to say that. A good many of the unemployed, of course, were living on relatives.

Colonel CHANTLAND. I was just wondering about that.

Mr. GILL. This problem, to the extent to which it was met, was met almost solely through the work of the Federal Government, the W. P. A., the N. Y. A., and the C. C. C.

The older worker also faces a situation of increasing difficulty. Studies made by the National Research Project and others have shown that while the older worker may have some advantage in maintaining his job due to the value of his experience, once he is displaced he is less likely to regain his job and far less likely to secure another job. The result of this and other tendencies to pass over certain workers in filling jobs from a crowded labor market has been the creation of a group of chronically unemployed, who constitute one of the most serious aspects of our unemployment situation. For the passage of time itself proves to be a factor in the distribution of employment opportunity, and those longest unemployed are likely to have the last chances for jobs for that reason alone. Such evidence as there is points to an increasing seriousness of this problem—an increasing number of able and willing workers who, in an economic setting characterized by a persistently large volume of unemployment, are chronically unemployed.

I would like to make a particular point with reference to these long-term unemployed. In Philadelphia, a diversified metropolitan labor market, we made a special study of this problem in 1936. The group studied had not only suffered unemployment of long duration but they had also been continuously on relief or the Works Program for at least 2 years. They were, then, one of the groups hardest hit by the depression. Over 30 percent of them had not had a private job for more than 5 years. These long-term unemployed numbered 20,000, or one-fifth of Philadelphia's relief load at the time of the study. They were an unwanted part of the labor market, but they were certainly not an undesirable part. By every available test these people were employable. They were out of work only because, relative to other job seekers, they had some disadvantages of age, sex, race, or type of occupational experience. The disadvantages affected not their ability to work but only their ability to get jobs.

In all, the situation that has developed, the wide-spread unemployment and underemployment, the inability of the younger workers to find a place in our crowded labor markets, and the increasing chronic unemployment, particularly of our older workers, presents a wide variety of problems for which a solution must be found.

These problems, both the general ones and the special ones which have been indicated here, are not, it must be emphasized, temporary.

The process of rapid technological and industrial change will continue to raise problems through prosperity and depression, as the process of displacement and reabsorption of workers continues. They are aggravated during periods of depression, particularly as in the present situation, when widespread and long-continued unemployment adds new considerations and raises new questions as to reemployment prospects of the persons affected. Any attempt to gain full employment of our manpower must take into account technological change and its action in continually jeopardizing the job security of workers.

EFFECTS OF TECHNOLOGY ON EMPLOYMENT

Mr. GILL. I should now like to draw some conclusions.

The effects of technological change on employment and unemployment present two distinct sets of problems. We have, on the one hand, the situations where particular groups of workers, in specific industries or localities, have been reduced to a condition of unemployment as a direct effect of technological changes. Such situations exist even at times when business is prosperous and employment opportunities are plentiful. We need only to recall the situation which prevailed, even at the height of prosperity in the late twenties, in some of our agricultural areas, in sections of our textile industries, and in some of the coal-mining districts. Such situations will be recurring even at the best of times. The adjustment, whether through migration, retaining, or development of new employment opportunities, may be a long process, much too long to be taken care of by present systems of unemployment insurance. A permanent work program would be well suited to meet such situations. It would help maintain the work habits and morale of the displaced workers and would aid them in the acquisition of new skills in a manner that would yield returns not only to the individuals concerned, but to the community as well, through the execution of socially useful projects.

The CHAIRMAN. May I interrupt there, Mr. Gill? The implications of the statement which you have just concluded, this first paragraph of your conclusions, would seem to be that the conditions at present are not such as to encourage business—let me see, you speak of it as though we were in a depression—we are in a period of unemployment, but I think the evidence which we may gather almost any day, in fact every day from the newspapers, particularly from the financial sections of the daily press, would seem to carry at least some basis for believing that business in many lines is steadily improving.

Mr. GILL. That is correct.

The CHAIRMAN. I was very much impressed during the testimony a few days ago of Mr. Watson, of the International Business Machines, who quoted from an article in the Reader's Digest or a recent issue, which summarized some of the new industries which have come into existence during the last 7 or 10 years. I was glad to have him make note of that, because I had myself alluded to it in the opening statement at the beginning of this hearing. He called attention, as I did, to the development of trans-oceanic aviation, commercial aviation, building of streamliners on the railroads, improvement in the telephone, and many new industries as a result of chemical discoveries.

All of these, I think, are common knowledge, and as you testified, they seem to have no difficulty in getting capital with which to finance themselves. The Transcontinental Airlines, for example, which have been doing such a remarkable piece of work in conquering the air and providing safe traveling—they just completed more than 12 months of commercial aviation without the loss of a single life—have apparently not had much difficulty in securing whatever capital was necessary for development.

We are, therefore, confronted with this anomalous situation, that science and invention bring new industries, but they do not create new jobs. I remember very well the report of the Standard Statistics Co., issued about 6 weeks or 2 months ago, on the fiscal affairs of the leading corporations of the country. It told of the profits of 669 of the leading industrials, railroads, and utilities. These 669 corporations have made net profits of more than \$1,250,000,000 in 1939, as compared with net profits of something less than \$700,000 in 1938, an increase of only 83 percent, and yet the unemployment problem remains.

It seems to me to be perfectly clear that a condition which allows the advance of business and an increasing profit for business, cannot properly be called a depression period; at least not in the old sense. It is a period in which we have been unable to adjust advancing technology to human needs in such a way as to create new jobs while we have in certain lines been increasing the opportunities for profit.

Mr. GILL. That is very true.

The CHAIRMAN. Do you agree with that statement?

Mr. GILL. Very definitely. We are not in a depression from a business point of view, even from the point of view of industrial activity if the comparison is with 1929, but from the point of view of employment, we certainly are still faced with a very serious problem, because the increase in activity in business and industry generally has not been accompanied by a proportionate increase in the number of people that they have had to hire.

The CHAIRMAN. We are told by the Federal Reserve Board Index that production is back—well, it is above 1929 levels, but unemployment apparently is below 1929 levels.

Mr. GILL. Well below.

The CHAIRMAN. Our capacity to produce has so far outrun our ability to consume that the lack of jobs is the result.

Mr. GILL. I would like to point out again, if I may, Mr. Chairman, that another very important aspect is that there are some 600,000 workers, net, entering the labor market every year, and you have got to expand your industrial production of business activity and your economy over the previous year to take care of 600,000 workers every year if you are going to maintain—even maintain—the same level.

The CHAIRMAN. Yes; the same level; the same ratio.

Mr. GILL. That is right.

A different type of situation confronts us in times of contracting business. The groups of workers who are unemployed, directly or indirectly, as a result of technological changes are many and varied. There are, first, those directly displaced by labor-saving devices introduced during the depression. But in addition to these, there are others whose unemployment reflects the previous course of technological progress, although not always in a directly traceable manner. They are the ones whose previous employment was in technically backward

or temporarily revived plants, and those whose employment was contingent upon equipment installations during prosperity when technological change went hand in hand with plant expansion, but who were dispensed with once the construction was completed.

In periods of depression, with widespread general unemployment, these displaced workers become one additional element of an excessive labor supply. Although their existence in the labor market tends to reduce the general chances for employment, they are not necessarily the ones whose opportunities are lowest. In the general scramble for jobs, they are not necessarily the ones doomed to constitute the "hard core of unemployment." They do, however, tend to make the core harder and heavier, and to make the criteria of selection on the part of the employers more stringent.

The incidence of displacement of labor through technical improvements in a depression is thus not limited to any particular group of workers, but its effects are diffused through the labor community. Remedial measures cannot, therefore, be viewed as a matter of mere readjustment of any concrete group or groups. The maintenance of a flexible work program becomes a matter of necessity under such conditions, but the fundamental problem is that of remedy against unemployment, the problem of recovery.

In the comparative recovery achieved since 1932-33, the main drawback has been the lag of the capital-goods industries. Technological improvements introduced in recent years have been many and they have had very substantial effects on the productivity of labor and on reducing costs of production. But, as I have pointed out, those effects have in many instances been achieved without incurring capital outlays large enough to develop the cumulative demand for capital goods which is necessary for recovery. As a result of the available technical improvements, not only cost reduction but also the expansion of productive capacity can be, and in many instances has been, affected with comparatively small capital outlays.

As long as technical trends of this nature continue to prevail, a growth of demand for capital goods in a volume requisite to make the recovery cumulative can be expected only from a flow of investments directed at quantitative expansion of production on a vast scale. The failure of private capital expansion in the thirties not only resulted in the lack of employment in the capital-goods industries but contributed to a further reduction in purchasing power by withdrawal of savings from the economy, which were not reinvested. This failure of private capital expansion and the increasing productivity during the thirties had to be offset to provide employment. This necessitated the large-scale public-works program as measures for the relief not only of the unemployed but also of the capital-goods industries.

INCOME DISTRIBUTION AND FULL EMPLOYMENT

Mr. GILL. The problem of income distribution is, of course, an important part of the problem of full employment. The increases in wage rates due to the spread of collective bargaining and minimum-wage and maximum-hour laws, the expenditure of funds for public works, emergency work projects, unemployment insurance, and other forms of social legislation and relief have contributed to the removal of some of the deficiencies of the distribution of income during de-

pression years. But with a view to bringing about full utilization of our resources, we need, in addition to the public policy of strengthening the purchasing power of the mass of consumers, a policy of directly promoting an expansion of demand for capital goods by direct investments by public bodies in large-scale undertakings and by stimulating private investment in other directions.

Public capital investment has, of course, and of necessity, always been a contributing factor in developing opportunities for private investment—notably in transportation facilities. The public development of streets is a necessary condition for the growth of cities and the development of local construction; the development of harbors and navigable rivers was a necessary condition for the growth of national and international commerce; use and development of railroads were necessary conditions for the growth of domestic commerce; Federal land grants and subsidies were necessary conditions for development of the railroads; the development of hard-surfaced highways was a necessary condition for the growth of the automobile industry; and the construction of airports for the growth of air transportation.

I would like to point out, Mr. Chairman, that the air industry, the Air Transport Association of America, have given W. P. A. credit for the fact that they are able to have commercial aviation in this country today on the scale that they have it. The Government has contributed, by a subsidy, if you will, as far as the private industry is concerned, by constructing 197 new airports in the country, and they have assisted in the remodeling and bringing up to date, so they can be used, 337 additional airports. If it hadn't been for that public investment in airports in the past 6 years, you wouldn't have the business in the air-line travel or the profits that are now accruing to the private companies.

The CHAIRMAN. It may be worth mentioning to call attention to the difference between the terminal facilities of the railroads and of the air lines. When the railroads were undergoing their period of expansion, the costs of building railroad stations and yards was, and still remains, wholly a matter of expense for the railroad company itself, but aviation has been able to progress without that burden of expense. The public has invested whatever capital has been necessary for the most part in building the various airports, and W. P. A., as you say, has contributed tremendously in that respect.

Municipal airports cover the country.

Mr. GILL. Mr. Chairman, don't you think the land grants that were given to the railroads have more than made up for the fact that the Government didn't do anything directly for the railroads?

The CHAIRMAN. Of course, the land grants did make up substantially, but the railroads continue to pay taxes on all this physical property. The air lines are not paying taxes, at least upon the airfields. Then, of course, whenever you raise this question with a railroad man, he will talk about the compensation which the railroads have rendered the Government by reduced rates on transportation of commodities.

Mr. GILL. The air lines do pay quite a heavy fee to municipalities for the use of airports, which, in a way, is equal to a tax.

Capital requirements for the phenomenal expansion of the use of the automobile are not limited to the planned facilities required for

their production, for the replacement of parts, and for providing the fuel for automobile operation. The expansion and use of the passenger car, the truck, and the bus depended upon Federal, State, and local cooperation in building roads. Total expenditures on streets, roads, highways, bridges, and tunnels thereby rose in rank second only to education in total public expenditures. Among other transportation agencies, aid to the new aviation industry was provided as early as 1926 by the Air Commerce Act, and the successive emergency work programs have established airways and constructed airports and landing fields. More recently a legislative provision has been made to aid in the construction of ships for a merchant marine.

Federal, State, and local outlays for all types of construction formed a substantial proportion of the demand for capital-goods production during the 1920's. This public investment, in addition to supplying the needs of private industry, aids the expansion of the capital-goods industries and therefore multiplies the amount of employment created and thereby expands the purchasing power of the Nation for more consumers' goods.

Reduction in hours of work would help to maintain employment; increases in wage rates would increase consumption and employment; special programs have been developed and are required to meet the special problems of youth and the aged. But the solution of the major serious problem of unemployment necessarily depends upon full utilization of our resources and manpower—the problem defined by the President, by the committee, and by the witnesses appearing before the committee, as idle men, idle machines, and idle money.

The CHAIRMAN. We have no difficulty in diagnosing the ills, but the doctor who will prescribe the cure hasn't testified to us yet.

Dr. ANDERSON. Haven't you in your conclusion indicated, Mr. Gill, that while there is no cure-all, there may be cures? In other words, you have indicated some of the treatments that can be administered.

Mr. GILL. I tried to; yes, Dr. Anderson.

Dr. ANDERSON. And you think the actual cure lies beyond even the summation of all these special things that could be done.

Mr. GILL. It lies in the full use of all our resources. As I said, apart from increased, more widely diffused purchasing power we need a public policy of direct promotion of expansion in capital goods.

Dr. ANDERSON. You reviewed the situation in industrial research, pointing out that the larger business enterprises were able to carry on research, had the facilities, and benefited by the results of such research. Mr. Kettering, I believe, answered by saying that time has removed the restraints that once were presumed to limit the benefits of such research to the companies actually performing it, so that now the smaller corporations and companies benefit almost equally with these larger units. Would you care to comment on that?

Mr. GILL. I would say that most of the research carried on by the large corporations is of a type that is directed to their own problems only, and cannot be converted and used by the smaller manufacturer or the smaller business enterprise.

Dr. ANDERSON. And you wouldn't see in patents, for example, any restraining influence that would benefit those who held the patents

for the period of the patent life as compared with those who didn't have access to such patents?

Mr. GILL. I should certainly think that the holding of a patent would be restrictive in itself.

Dr. ANDERSON. You indicated in your testimony that technological advance in the field of agriculture benefited particularly larger agricultural units.

Mr. GILL. That is correct.

Dr. ANDERSON. We have heard testimony that a technological development, the all-purpose tractor, with small farm units of equipment, might set a new trend which would enable small farms, farms of 50 to 100 acres, to remain in business on competitive terms with these larger units. Have you gathered any data on that point?

Mr. WEINTRAUB. That is perfectly true, but the development of the small tractor is rather recent. All the material we have been able to gather on the relative efficiencies of small and large farms would tend to indicate that the larger farm today and in recent years has certainly been able to operate with less labor per unit of product than the small farms. What the all-purpose tractor eventually will do, we don't know, but the vast majority of the farms still don't have any tractor at all, large or small.

Dr. ANDERSON. Those are the questions I had, Mr. Chairman.

The CHAIRMAN. Thank you, very much, Mr. Gill. We are very much indebted to you.

Dr. ANDERSON. Mr. Chairman, our final witness is our own committeeman, Dr. Isadore Lubin, head of the Bureau of Labor Statistics, Department of Labor, who will testify at this time.

TESTIMONY OF DR. ISADOR LUBIN, COMMISSIONER OF LABOR STATISTICS, DEPARTMENT OF LABOR, WASHINGTON, D. C.

Dr. LUBIN. I think that the committee is perfectly conscious of the fact that there was once upon a time a year known as the year 1929. I do not know, however, whether this committee is conscious of the fact that exactly 11 years ago, to be specific, on the Senate calendar day, March 1, in that year 1929, the late Senator Couzens, at that time chairman of the Education and Labor Committee of the Senate, submitted a report to the Senate on the problem of unemployment.

I should like permission to take a minute to read 2 or 3 short paragraphs from that report. This, I want to reemphasize, was on March 1, 1929, when approximately 1,400,000 more people were employed in nonagricultural activity than are employed today, a year in which we, most of us, believed there was no problem of unemployment of sufficient size to concern the American people. In that report, issued in that year 1929, the statement is made—

During the past year or two, much has been said in the press and in public discussion about the great amount of unemployment that has resulted from technological changes in industry. Machinery and discovery are every day displacing men whose lives have been spent in developing the skill and ability necessary to their crafts. Efficiency methods which aim at eliminating wasteful and unnecessary processes are daily eliminating workers from industry. At the same time the amalgamation and mergers which have recently been going on at a pace faster than ever before in history have resulted in closing down factories and in moving plants and warehouses from one part of the

country to another. The declining markets for certain products resulting from the changing habits of consumers have also led to the shutting down of plants. Bankruptcy is also taking its annual toll of employers of labor, a tendency which we must assume will go on forever in a Nation which attempts to give full play to individual initiative and relies upon free competition to regulate its economic activity.

All of those forces make for unemployment; in good times and bad times they are relentlessly at work. Under the accepted competitive theories, it is assumed that they eventually lead to greater efficiency, lower production costs, and lower prices to the consumer. They are part and parcel of progress. The question arises, however, as to whether the laborers who are thrown out of work as a result of these movements in our economic life should be made to pay the price of such progress. Is it just that society should benefit at the expense and suffering of the dispossessed worker?

And one final paragraph included in the report of Senator Couzens to the Senate in March 1929:

Technological unemployment covers that vast field where through one device or another, and chiefly through a machine supplanting a human, skilled workers have found that their trades no longer exist and their skill is no longer necessary. What becomes of these men? What can be done about these thousands of individual tragedies? What do these individual tragedies mean to society as a whole? It is an imponderable thing. Some of the experienced witnesses who appeared before your committee stated that new industries absorbed the labor turned adrift by machine development; the automobile, the airplane, the radio, and related industries were suggested as examples.

Undoubtedly there is much truth in these statements, but, nevertheless, we are not relieved of the individual problem. It offers little to the skilled musician to say that he, who has devoted his life to his art, may find a job in a factory where radio equipment is manufactured. Then there is the little aid that in every period of idleness when readjustments are being effected, the suffering, the loss, the enforced change in environment. True, this may all be the price of progress, but society has an obligation to try at least to see that all this does not become the burden of the worker.

The CHAIRMAN. Would you be good enough, Dr. Lubin, to turn to the front page, the cover of that report, and see if you find there the list of the members of the committee, and read it into the record?

Dr. LUBIN. James Couzens, chairman; William Borah; Lawrence C. Phipps; Jesse H. Metcalf; Hiram Bingham; Frederick H. Gillett; Royal S. Copeland; Lawrence D. Tyson; David Walsh; Cyrus Locher; Morris Sheppard.

Mr. MAGINNIS. Dr. Lubin, to me, that is very interesting. May I ask, I didn't hear clearly, did you state the number of unemployed in the year '29 as compared with today?

Dr. LUBIN. No, I did not. I said that during that period, the spring of 1929 when this country was going along full speed toward that peak which culminated in the fall of the year, we were not conscious—when I say "we," I mean the rank and file of the American people—of the fact that there was a problem of unemployment on our hands, and this report, as I say, issued on the 1st of March 1929, restated in a sense the gist of everything that has been presented to this committee in the last few weeks.

Mr. MAGINNIS. Did it state the number of unemployed at that time?

Dr. LUBIN. In the report it was estimated that the number of unemployed was in the neighborhood of 1,000,000.

Mr. MAGINNIS. Of 1,000,000?

Dr. LUBIN. Yes.

Now, Mr. Chairman, 11 years later, the same problem that was presented to the Senate of the United States by its Committee on

Education and Labor has come to the forefront. We had witnesses here from every important branch of industry testifying to the existence of the same problem that apparently prevailed, and of which there was very definite evidence, in 1929.

The problem today, of course, is much more acute, because, as Mr. Gill pointed out a minute ago, a larger proportion of our labor supply is unemployed. In other words, the large unemployed mass that has to be absorbed by industry makes the problem of those who have been displaced by technological changes even more acute than it normally is. Under these conditions technological unemployment intensifies the whole problem of unemployment. What I should like to do with your permission is to point out the different types of problem involved as they have been presented to this committee and attempt to differentiate the causal factors that must be differentiated if we are going to deal with this problem at all.

In other words, all sorts of instances of so-called technological unemployment have been cited to this committee and yet no single cure-all, whether it be prosperity with full employment or some other general program, is going to solve the problems presented by technological progress as it affects workers. This is a fact which must be realized and accepted if this country is to go on and if progress is to continue. As a further matter of fact the worker's problem in facing technological change is not always the same. The character of his problem depends in large part upon the type of change involved and upon the conditions surrounding its introduction.

FACTORS AFFECTING LABOR PRODUCTIVITY

Dr. LUBIN. I have attempted to break down the types of factors that affect labor productivity. If I might say so, the thing that has impressed me most about these hearings has been that we have been talking about labor productivity as a problem in itself, as it were, without differentiating (and it was impossible, of course, to differentiate with the types of witnesses we had) the factors that bring about these changes in labor productivity.

Now, I should like to list for the record what we might call five different types of factors which affect the productivity of labor.

The first, as I said, is changes in technology, and these changes in technology may in turn be divided into four subdivisions. The first of these changes in technology are those that make possible the creation of new kinds of wealth—in other words, they are the types of technology which create new employment and bring about little or no direct or indirect displacement of labor.

The second is that type of technology that creates substitute products.

The CHAIRMAN. Can you give an example of each one?

Dr. LUBIN. I want to come back to that, if I may, Mr. Chairman. I just want to list them first and then come back.

There is technology which creates substitute products, and it does so by displacing other products. Some of this technology that creates substitute products, creates net unemployment; in other words, adds to the total number of unemployed in the country. Others create net employment. But all of them cause some direct displacement of labor, although the net to the country as a whole may be a gain or a loss.

The third type of changes in technology is the new methods of production, where you do not necessarily create a new product at all, but you substitute machines or tools for human workers.

Now, these three types come under this heading that I should like to call changes in technology, as distinguished from other factors that affect human productivity.

I also want to add a fourth, at this point, because it apparently will become increasingly important as time goes on, and you might call it labor-and-capital-saving technology. In many cases today new methods make possible not only a direct saving of labor through the introduction of new machinery, but it frequently happens that the new process involves the use of less capital as well, and thus results in an indirect saving of labor in equipment producing industries.

As I say, those four groups come under what I should like to term changes in technology.

The second factor in improving human productivity—and one which, incidentally, according to many of the witnesses who testified here, is of much more significance—is changes in the way of doing things. They are those changes that we might call managerial changes, that reduce labor requirements but do not substitute machines for human labor, and it is quite evident that in many industries, these managerial changes cause more displacement and increase productivity at a greater rate than revolutionary changes of a technological type.

The third type of factor that affects the productivity of labor might be put under a group called changes in types of raw materials. By using a new type of raw material to make the same product, you may require less labor.

The fourth is an increasingly important factor of changes in human productivity by changes that have been occurring in management-labor relations; the sheer change in the psychology of relationship and the conditions of relationship between the employee and management has had tremendous effects in many instances upon productivity of labor.

And finally, a very important factor, particularly in periods when the plant or industry is moving from low rates of production to high rates of production, is the relationship of output to capacity which affects the productivity of labor. In other words, a plant running at half-time requires more man-hours to produce a given number of units than if it were running at full capacity. There is no change in technology, no change in methods, no change in fuel or anything else, but the ability to get more use of your capacity through greater operation.

The CHAIRMAN. Well, why does it have that result?

Dr. LUBIN. Let me give you a concrete illustration: In the case of the steel industry, when you operate at 20 to 25 percent capacity, you require 35 percent more man-hours to produce a ton of finished product than when you are operating at 55 to 60 percent.

The answer, I think, is simple; to get 25 percent you have got to have a minimum number of men to keep the furnaces going, to keep that plant in operation, and you cannot operate with less than that minimum. Now, that same number of men, with the same machines, can produce twice as much, frequently—in the case of the steel indus-

try, 35 percent more—by just having more to do, with the same plant and the same equipment.

The CHAIRMAN. I can understand that an administrative force would have to be maintained in any factory regardless, or almost regardless of its size, but it would appear to me that that would not also be true of the labor force. When you talk about man-hours, required in production, do you refer to the entire labor force, including office management and so forth, or only to those who are paid by an hourly rate?

Dr. LUBIN. Even in the manufacturing process, you must have a certain number of people present to keep these furnaces going. To take care of them, you have to have a certain number of men at the machine, whether it turns out 1 unit or 100; and during periods of increasing industrial activity such as that between 1932 and 1940 (and I think it is rather important that we note this fact), this closer approach to capacity operation has in itself, without any change in management necessarily, brought about increased productivity of labor.

Mr. O'CONNELL. Yes; but that is a partial measurement of the extent to which your unit cost would decrease when you—

Dr. LUBIN (interposing). It is the unit labor cost. We know that the man-hours required, given the same wage rate, would be 35 percent less when you operate at 55 to 60 percent than it would at 20 to 25 percent.

Mr. O'CONNELL. Likewise, because of fixed charges, I take it that the unit cost would also tend to go down?

Dr. LUBIN. Yes.

Dr. ANDERSON. Is there a point where this difference tends to fade out?

Dr. LUBIN. Apparently there is, but we haven't found it. As a matter of fact, this study is based on an investigation that we made in the steel industry in 1935, and we are now trying to make arrangements to bring this thing up to date, because the industry, at no time during the period we covered, exceeded 65 percent capacity, so we had no record.

Dr. ANDERSON. And do you have it for any industries other than steel? I can understand the situation more easily in steel than I could in some more diversified field, or in one more completely organized on a belt line.

Dr. LUBIN. Well, your rate of change, of course, would differ with different industries, but there probably is a stage in every industry where you must have a minimum number of men to produce anything at all. I can hardly think of any industry in which capacity operation does not reduce unit labor time for maintenance workers. Steel is probably an extreme case of saving in direct labor costs, but it is by no means unique.

Dr. ANDERSON. Yes; that is true.

Dr. LUBIN. And the point at which you get into the period of, say, decreasing returns will vary with the type of product you are making and the type of investment you have.

In coal mining, that is a very significant fact; in other words, even when you shut down you have got to have your company force, your air force, you have got to have your men seeing that the roofs

don't fall in, and all that sort of thing. Frequently it is cheaper to maintain a mine at 5 percent capacity than to shut it down, because if you did shut down you would lose everything. So it is worth while putting in some investment so you can use the mine when you want to.

Now, I am going to touch briefly on the various types of technology that come under these different classifications that I have mentioned.

WORK-CREATING TECHNOLOGICAL CHANGE

Dr. LUBIN. Under the types of work-creating technology, where most of the employment created is net gain and there is little or no displacement of labor, either direct or indirect, the advantage is self-evident. With the telephone and telegraph, of course, you had some displacement of the pony express, but by and large there was a very great net increase in employment. There are photography and the development of the phonograph, air-conditioning, the pneumatic tire, the development of a number of medical supplies. The radio did supplant vaudeville actors, but the net increase in employment was rather marked. The same thing is true of most household electrical appliances, like vacuum cleaners and waffle irons, and all of those thousand and one electrical devices which create new products and which do not supplant them in other industries.

The CHAIRMAN. In referring to the telephone industry, I assume that you are thinking of it in terms of its entire life and not in terms of its recent life, during which the dial system has been introduced?

Dr. LUBIN. Yes; well, the technological changes that have occurred in the industry in recent years have not changed the product that we get. Those have been changes in the ways of giving us the product. I am thinking of the development of the telephone instrument as an instrument of communication, you see. It may temporarily have supplanted some messenger boys, but even immediately it created more employment than it displaced.

The CHAIRMAN. But the record offered to this committee with respect to the introduction of the dial telephone was that there has been a complete displacement; that is merely a segment in this larger picture to which you refer.

Dr. LUBIN. Yes.

Now, among those types of technology that create substitute products or substitute outlets, there is again a whole series of instances that are known to everybody here. In such cases the net change of employment may be large or small. It may be an increase or a decrease. But in all such cases some people are displaced, even if on balance there is an increase in total employment.

Take automobile and truck transportation. There is no doubt that automobile and truck transportation displaced a large number of people who were engaged in activities which had to do with horse transportation, but offsetting that you had road building and petroleum refining and steel and rubber and textiles and glass and real estate, and a thousand and one other activities that were not possible without the automobile. So there again there was a net increase in the number of people employed.

The gross increase in employment in these new activities was, of course, offset by the displaced employment in vehicle industries

and stables and raising mules and horses and water transportation and horse training, but, by and large, we will admit that the net has been a gain to the country as a whole in the total number of jobs.

Again, there are the movies. You had employment created in book writing and in making film and in the production of movies and distribution of movies, and that net was greater than the number displaced among vaudeville artists and musicians.

Rayon is another case in point. Through improved quality and through lower prices, there has been an increase in employment, which was offset in part by losses in the silk industry and in other natural fibers, like wool and cotton.

Electric power created employment through endless possibilities for cheaper light and cheaper power. On the other hand, it created unemployment in coal and gas and oil, but again I say there was a net increase for the country as a whole.

LABOR AND CAPITAL SAVING CHANGE

Dr. LUBIN. The third type of technological change that affects human productivity is new processes for making the same product or the same service with less human labor. The chairman mentioned the telephone as a case in point. In other words, the same service is given to us, we get exactly the same product but it is given to us in a different way, and in that way human labor is conserved.

Mr. PIKE. Miss Sullivan said that you changed the labor from the telephone employees to the subscribers. She said there wasn't any displacement.

Dr. LUBIN. Well, I said displacement of employment.

Mr. PIKE. Yes; I believe she used that word.

Dr. LUBIN. And, of course, one could, under this third category, mention a whole series of revolutionary changes, like automatic machinery instead of semiautomatic or hand operation. Among those you have the automatic cigarette-making machine, bottle-making machine, the hot-strip mill, automatic drills, electric welding—and one could go down the list.

The fourth type in this group of technological changes is what I call labor and capital saving devices; in other words, more efficient or better utilization of the things we are working with. We have heard a lot from witnesses this morning and witnesses this afternoon about coal and the locomotive. Take the case of the Diesel engine. That is an awfully interesting situation. The Diesel engine makes it possible to keep traffic moving day after day, year in and year out, without having to have the expensive equipment and the labor force necessary to keep it serviced.

I think I read of one the other day that had been in service exactly a year and a month and had been to the shop once. It ran 365 days a year, which makes it possible for 1 engine to do the work of 4, because you can use it 4 times as long in 24 hours, which is not only labor saving but also capital saving. You need only 1, whereas formerly you needed 4, and yet the power may be the same or even less.

Similarly, we have had examples cited here of better and more lasting equipment. Take the case of the creosoted tie. A creosoted tie costs more than one that is not creosoted, but you have to replace it only once in 21 years, whereas the old ones, uncreosoted, you had to

replace every 7 years; so that over the life of the tire you save as much as two-thirds in some instances. Again, that means not only saving labor because you have to replace it only once in 21 years, but saving capital.

Mr. Pew mentioned the case of new developments in his industry which make it possible to get 92-percent¹ realization of gasoline out of a barrel of crude. Again, that is saving not only labor but it is a capital-saving device. One plant with a given investment can turn out so much more than another plant could with the same investment.

Probably the best case we have is the modern automobile tire. You replace it once in 20,000 miles, whereas you formerly replaced it every 7,000 miles, which conserves labor in changing, selling, servicing it, and at the same time saves your capital investment, of course.

One could go on to cite cases of mergers and consolidations which bring about the same result. Also better materials are used in tools. Mention was made this afternoon, I believe, that by using a certain type of steel in a tool the tool would last so much longer, although it is exactly the same tool. The composition of the tool makes it possible to save both on the labor in using it and in the capital in replacing it.

The second series of factors which I should like to emphasize particularly bring about changes in labor productivity which are not technological in character, in the sense that they necessarily involve scientific discoveries or the application of new methods or even new materials. They are those changes which are due to managerial progress and result in reduced labor costs. There are no new machines used, no supplanting of machine labor or power for hand labor, and yet a very marked increase in the productivity of labor. You probably will remember Mr. Rieve, of the Textile Workers Union, and Mr. Merrill, of the Office and Professional Workers Union, emphasizing the fact that these changes that management makes, eliminating waste here and there, in their opinion, have caused much more reduction in employment in their industries than any mechanical changes that have occurred in recent years.

Instances can be cited in the shoe industry and the textile industry and in dozens of industries where by just changing the routing of your product, eliminating lost motion, as it were, in the mere movement of the product, has led to a tremendous increase in the efficiency of labor.

We made a study recently of the so-called bundle system of operation as opposed to the line system of operation in making cotton garments. The only difference between those two systems is this: In the old bundle system each girl went to the office, or wherever the goods were given out, and was given a bundle of pieces. She took them to her machine, sewed them together, put them back in the bundle, and returned that bundle to the office. Under the line system, one girl gets a bundle or somebody brings the stuff to her, she sews the two pieces together, just pushes it forward, and the girl in front of her takes it and sews it some more, and hands it to the girl in front of her, and so on until the garment is completed, and it is estimated that this change has increased the output of the workers over 20 percent. We have the same machine, the same fabric, the same

¹ See hearings, Part 14, p. 7190, and Part 15, p. 8350.

thread, the same temperature, everything is identical. The only change is in the way the work is arranged.

Let's take the case of job analysis and time-motion studies. The various systems that have been employed in various industries all give evidence of very marked increases in productivity of labor and the displacement of labor with no change in mechanical methods of production or in products made or used.

I might instance one other case in the steel industry. There is evidence that the elimination of job hazards and accidents and the bringing about of a very low accident rate as compared to the high one they had 25 years ago has affected the efficiency of the workers and there again, as I say, with no change of any significance in the type of production.

CHANGES AFFECTING RAW MATERIALS

Dr. LUBIN. Now, the third type of activity which affects the productivity of labor is changes in the types of raw materials used. You can't stamp cast iron, you can stamp sheet steel, and by the substitution of sheet steel for cast iron you can make all kinds of bathroom materials, bathtubs, lavatories, and so forth, and turn them out at a terrific rate, whereas when you make a cast-iron bathtub, you have to cast it and let it set and take the time for hardening, and so forth. It might interest the committee to know that just within the past 2 weeks the manager of one of the smallest steel plants in this country told me he was going to put in a strip mill. He has a hand-rolling mill now. I asked him why, because I felt that his mill was small for a strip process. He said, "I have to do it to meet competition. The product of the new rolled-sheet mill apparently lends itself more effectively to stamping than this hand-rolled product, and in order to meet the competition of these new rolling mills, I will have to put one in, because the people in this particular country"—it was in the far West—"are increasingly using sheets for stamping purposes." In other words, the major part of the demand was for making of steel products that were going to be stamped for refrigerators, and a thousand and one things. Now, the type of raw material in his plant is going to affect the output of his workers because he can get a product through this new mill that he can't get any other way, and when he puts the new mill in, he won't have to have as many people as he formerly needed.

The CHAIRMAN. Are all of these effects which you have been discussing evidenced in increased productivity?

Dr. LUBIN. Every one of them, but I think the significant thing is that the causal factor isn't somebody making a new machine and putting it in.

Dr. ANDERSON. You wouldn't say these so far enumerated factors operate in the majority of instances, or instances unknown in amount or number?

Dr. LUBIN. They are all happening all the time, everywhere.

Dr. ANDERSON. So that is one of the reasons we get this clouded effect and the inability to differentiate between causes.

Dr. LUBIN. Yes; and I think we are going to have to differentiate if we are going to attack the problem.

I mentioned as the fourth type of factor that affects production, the type of labor-management relations, the hours of employment in a

plant. One of the outstanding facts in the coal industry immediately after the shortening of hours under N. R. A. was the increase of productivity per man per day, before there was time enough to change methods of production. The methods of wage payment affect productivity. It has been found that under a group bonus system where a group of people work together and share the total amount paid to the group and they get a bonus after they produce a certain amount, it has almost in every case increased the output per worker. We have found in a report that we shall make to this committee very shortly that there are many plants in this country that pay much higher wages than any of their competitors, and when I inquired of them why they paid almost 50 percent more than their competitors, they said that by paying a higher wage they get the cream of the workers and their people produce more with the same methods that their competitors use.

The guaranteeing of employment has been known time and time again to increase productivity. A man knows that he has a job, he is not going to work himself out of a job, he is going to be taken care of. It affects his morale and his productivity moves up, and you will find many plants where the fact of security plays an important part in the picture. And I might even go a step farther. In some instances, the signing of a union contract has automatically increased productivity. The men have felt secure, they have felt they have something to protect them, and the union itself by giving this protection has been a factor in increasing the morale of their people, and output per man has gone up.

Of course, one must admit one can cite contrary instances, too, but those are factors that are working every day and must be distinguished from the machine or invention or new processes.

It is quite evident that by now what I am trying to emphasize is the necessity for distinguishing between productivity and technological displacement. It is quite evident we are confronted with a whole series of problems. It isn't the machine alone, and because there is a whole series of problems, I personally do not think that we will find a single solution to it.

Mr. Gill dealt rather elaborately today with the question of the ghost town. The ghost town was discussed in our hearings when the steel industry was discussed, and we heard the story of what the new rolling mill has done to certain communities.

As Mr. Gill pointed out, in New England today, and not only today but during the twenties, ghost towns were being created every year. Mills moved away, particularly from the textile areas in New England, because sometimes they could get cheaper labor, sometimes because of lower taxes, sometimes they got freedom from taxes entirely, and sometimes they were even given a brand new mill. On the other hand, ghost towns are being created every day by the exhaustion of raw materials. Northern Michigan is dotted with ghost towns that once thrived when there was lumber there. In the Southern States you will find areas of ghost towns where the raw material has been exhausted.

I have known of a ghost town that was created by a change in freight rates which affected the competitive position of the manufacturer in that community; he couldn't stay in business, so that it is quite evident that again no single solution is going to take care of this problem.

In the case of lumber, if we are going to eliminate the ghost town we are going to have to do it through selective logging or through some conservation program. In the case of cotton, or shoes, in New England—and ghost towns have been created in New England in the last 5 years by plants moving away from Massachusetts into Maine and into Vermont where prior to the wage-and-hour law they were able to get labor at lower costs than they would have to pay in Massachusetts.

In other words, all these phenomena of moving, bankruptcy, and disappearance of raw material, create what appears to be the same problem, namely, the ghost town in stranded areas, but they arise from different causes. And I think the significant thing that should be emphasized is that in this period of mass unemployment it is impossible to tell where technology has been the cause and where other factors in the economic picture are responsible.

I think that one wouldn't be going far afield in reporting what Senator Couzens' report to the United States Senate said; namely, that these are problems of competitive economy, they are problems that arise out of a desire to improve your own profit position if you are in business, and the fact that we have never compelled those who benefit from these changes to bear the burden of the costs involved.

SOCIAL ACCOUNTING FAULTY

Dr. LUBIN. Frankly, the problem of technological displacement, particularly, I think can be attributed to bad social accounting and to bad social bookkeeping. In other words, we haven't recognized the fact that progress, improvement, a better way of living, involve hazards for somebody. The hazards have been borne for the most part by labor, and nobody cared about it. You and I, who got a better product at a lower price, or the employer who got a better profit, didn't have to bear that burden. It was only because of this displacement that it was possible for us to get a better product and perhaps cheaper prices, and we took all the advantage to ourselves insofar as it was given to us, and the employer took as much of the advantage as the competitive system would let him have in higher profits, and we refused to recognize the fact that there was a hazard there, that somebody was bearing part of that cost, and we refused to share the burden of bearing that cost with him. That cost was borne by the displaced worker.

Now, as again Mr. Gill pointed out, the problem of this type of unemployment is accentuated during periods of abnormal depression. But we must not attribute our problem of unemployment entirely to technological change. Certainly we can't hold any of these forces that I have briefly outlined here responsible for the unemployment situation that appears today in the cement industry. There have been radical changes, no doubt, but, those changes don't account for the fact that the industry is only employing 60 percent as many people as it did in 1923-25.

Dr. ANDERSON. That exhibit is admitted.

(The chart referred to was marked "Exhibit No. 2784" and appears on p. 17254.)

The CHAIRMAN. Just let us see what that comparison is. What was the peak?

Dr. LUBIN. During the period 1923-25, during the seasonal period, the index was 100.

The CHAIRMAN. The base is what?

Dr. LUBIN. 1923-25.

The CHAIRMAN. That is 100?

Dr. LUBIN. Yes; and you will note the highest the index of employment has reached since 1930 was in 1937, when it temporarily reached about 76; it is now down to 59.4, which means that for every 100 people they employed in 1923-25 they now are employing approximately 60 people.

Similarly in the case of structural and ornamental metal work.

(The chart referred to was marked "Exhibit No. 2785" and appears on p. 17254.)

Dr. LUBIN. You will find the same picture there. The industry is now operating at the point where it is employing 703 people for every 1,000 it employed during the period 1923-25.

The CHAIRMAN. And the cause in these instances was?

Dr. LUBIN. I will come to that in just a minute. In the lumber (sawmill) industry employment at the present time is at 59.5, which means that 60 people are being employed for every 100 formerly employed.

(The chart referred to was marked "Exhibit No. 2786" and appears on p. 17255.)

Dr. LUBIN. In the brick, tile, and terra cotta industry approximately 55 people are being employed for every 100.

(The chart referred to was marked "Exhibit No. 2787" and appears on p. 17255.)

Dr. LUBIN. The explanation of these changes in employment, I think, is found in this chart on the Value of Building Construction, "Exhibit No. 2788."

(The chart referred to was marked "Exhibit No. 2788" and appears on p. 17256.)

Dr. LUBIN. Unless you are building houses you are not going to get employment in these industries. There is no doubt that the technological changes that have occurred in these industries are such that we can get back to our former levels of production without necessarily reaching the former levels of employment, but the major problem of unemployment in these industries is due to conditions that exist in the building industry. There, I think, we have a series of factors which were discussed before this committee last summer: the cost of building materials, the cost of financing, the labor costs of building houses, and a thousand and one other items.

My sole purpose of bringing in these charts is to point out that if you can solve technological unemployment tomorrow, that isn't necessarily going to affect the picture in housing.

As I said, during these periods of depression this problem of technological unemployment becomes accentuated because you add to an already large volume of unemployment more unemployed to make the problem still more severe. It is accentuated also for another reason which is that during periods like the present we become socially conscious that the problem exists. We are trying to find an answer. Some Members of Congress were interested in finding an answer in 1929, but the American people as a people weren't

CONCENTRATION OF ECONOMIC POWER

interested. But when you have a problem of unemployment and you are trying to find out what it is all about, these other factors, everything that impinges upon it, becomes very, very important and you become conscious of them.

The displaced worker, however, has always been conscious of the problem, and he was just as conscious in 1929 as he is in 1940. But society wasn't, and society has been forced into that period of consciousness, as I said, because of a general abnormal economic situation rather than by these technological changes.

DISPLACEMENT AND THE YOUNG AND OLD WORKER

The CHAIRMAN. Of course the testimony of Mr. Gill emphasized that the displaced worker doesn't make up all of the unemployed, that we have now confronting us the worker who never had a job and therefore never could have been displaced.

Dr. LUBIN. Well, he was displaced in a sense, in part, to the extent to which his ability to get a job, even in the 1920's, was delayed. He may have been absorbed, but the need for taking him on was not as great, due to the greater efficiency in operation.

The CHAIRMAN. Not alone that, but as you, I think, have very correctly pointed out, due to a number of other factors which have increased the productivity of labor, not alone the machine, but all of these accumulating factors. But the thought occurs to me that while it may be true that we cannot assign to technological unemployment responsibility for the entire situation, if we look at it from the point of cure, we probably are compelled to come to the conclusion which was reached by Mr. Gill, namely, that unemployment is the central problem, unemployment whether by reason of technological advance or by lack of demand or new industries, of which you have spoken, or any of these factors. So that anything that contributes to providing employment, whether by machines or by hand labor or by new industry or what not, will by that very fact create increased consumption and thereby tend to overcome all of the factors which you have set forth.

Dr. LUBIN. I think very definitely; as a matter of fact, that is the conclusion I am gradually getting to. Before I get to it, though, I would like to point out one other factor, and it is the other side of the coin that Mr. Gill pointed to when he talked about the youth. He also mentioned the old worker. I think it is worth while emphasizing what Mr. Hook said in part and what Mr. Murray implied, that this problem of displacement, whether it be through machines or for other reasons, becomes ingrained in the public conscience because, during periods like this, displacement through any radical change in methods of production puts a rather heavy toll, probably a heavier toll than usual, on the old worker. In the steel industry, as Mr. Hook stated, the plants that were shut down were the less efficient plants, the more obsolete plants. Now the more obsolete plant is the older plant usually, and the older plant usually has more older workers; in other words, there are people there who grew up with it, stayed with it, and the result is that as you shut down these obsolete plants during a period of competitive stress, whether it be due to sheer competitive conditions or the invention of new methods, by shutting down those plants the proba-

bility is that you are throwing more older people onto the market than the general run of industry is doing. Of course, the older worker, during periods of very keen competition on the labor market, with more younger workers there looking for jobs, comes into a tight labor market and finds still more difficulty finding a job. As it is, he would have some difficulty, more than the youngster.

So because of the nature of the type of plant that is shut down because of these newer processes, you accentuate the problem of the older worker and you lengthen his period of unemployment, and again force back into the public consciousness the fact that it is the machine or the new process that has been a responsible factor, whereas the responsible factor may have been, probably is, for the most part, the tight labor market.

Despite the great scientific progress and the severity of technological displacement that has occurred, I cannot accept the idea that this is a permanent burden on society that we are never going to solve. I think that as unemployment decreases, as the economic system absorbs more and more people, the severity of the aftermath of technological displacement will become progressively less. In other words, I feel that the severity of the problem of technological displacement is geared into the whole question of the problem of recovery, and I believe that with the growth in the economy, as more goods are made, more services are available, and these goods and services are better distributed, as the national incomes goes up, you have a higher standard of living, and the impingement of these technological changes upon the employment situation will become progressively less severe.

But that is not to say that the problem is going to disappear, because even if we have full employment it is going to crop up every day at particular points and particular plants in different ways, and it is only during periods of more or less full employment that you can actually distinguish the technological element from all these other forces that operate. Of course, one can distinguish these forces today when you get a radical thing like a new steel mill going up or a new plant being erected, but by and large it is next to impossible to attribute a particular unemployment to a particular technological factor.

As I say, that problem is going to exist, it is going to keep cropping up, and will be appearing in every segment of the economy even though you have great industrial activity, and the question arises as to how the problem should be coped with. Again I am talking only about this specific problem of displacement.

DISPLACEMENT COSTS PAID BY WORKERS

Dr. LUBIN. I think one thing is evident, as shown by the testimony before this committee, that everybody is agreed the displaced worker should not bear the cost. I personally think that the cost should be borne by those who benefit from displacement. I think that industry, which profits by these displacements, and consumers who profit by this displacement should share some of the burden with the displaced worker. We have already given recognition to this principle of putting the burden upon those who benefit in our Social Security Act.

We have said in our Social Security Act to the ladies of this country, "If you want to buy your Easter bonnets in April and no other month of the year, and you are going to go without another hat until next fall, you are going to have to pay part of the cost of taking care of these unemployed during the period when you don't want to buy hats," and we have assessed the employer, we have taxed him, and those taxes are put into a pool, out of which funds are given to these unemployed workers. By taxing him we have made the cost of maintaining these people part of the cost of production, and you and I, who get the benefits of these services and you and I who can have all of our whims catered to, who buy today or tomorrow, are bearing part of the cost of taking care of these people who are in their present condition partly because of our whims and habits of purchase.

We have recognized that same principle in workmen's compensation. For over a generation now, workmen's compensation has been an accepted part of our economy. All but one State have workmen's compensation laws.

Now, how does the workmen's compensation law operate? Well, it says there is a hazard in industry. You and I want the products of this industry, and there are certain hazards to the worker in the industry and we must pay for those hazards. So the employer pays a premium on his pay roll, which again is attached to the cost of production, which he adds to the price which we pay, and if a man is injured, he is taken care of with those funds that you and I as consumers pay through the cost of production.

The CHAIRMAN. Of course, one difficulty about laws of that character is that they deal with only a segment of the problem; they deal only with the industrial worker in the sense of the worker who is employed in manufacturing or mining or work of that kind. There are usually exemptions, as in the Social Security Act; the agricultural worker is not included at all.

Dr. LUBIN. Of course, I would advocate the expansion of the coverage. Take the case, probably the best case we have, of the houseworker. A woman wants somebody to come in and help her just for 3 hours one day, and there is a person there to do that for her. During the rest of the week either W. P. A. takes care of the house worker or her family takes care of her. The way we have organized our method of living in this country a lot of people only want a person for 2 or 3 hours a day, and I feel that if I want that luxury I ought to pay an unemployment-insurance premium when I hire that person so that I will be paying my share of taking care of her so that she will be there next week when I want her.

Now, in the case of workmen's compensation we have said and the courts have held, that if a person is partially disabled he shall be entitled to a certain income, and partial disability has been interpreted by the courts as including inability to earn wages or full wages at the employment in which the employee was working at the time of the injury. In the State of New York we pay a man as much as 66 $\frac{2}{3}$ percent of his wages, with a maximum of \$25 a week, for as many as 6 years, and a man can get \$7,200 in cash over a period of 6 years in New York if, because of an injury, he can't go back to his old job and earn the wages that he formerly earned.

I can't see any distinction between my being unable to go back to my old job because I have lost a couple of fingers and not being

able to go back to my old job because a machine took my skill away and I am no longer needed. Yet in one case we have recognized the responsibility of society to take care of these people, and in the other case we have paid no attention.

Mr. O'CONNELL. Under the workmen's compensation law you get the compensation even though the injury were not your own fault, and clearly a man who is unemployed because of the economic situation is not to any extent responsible for his condition.

Dr. LUBIN. Or go a step further. Take the case of obsolescence of machinery. You put a million-dollar investment in a plant and equipment, and if somebody comes along and puts in something new, a change in the art, that obsolescence loss can be charged to depreciation, because of the accounting and tax structure, and it becomes a part of the cost of production. Many a firm has an obsolescence fund which they accumulate each year and it is charged to the cost of production, and you and I as consumers are making provision for that firm or that industry against the possibility of that machine becoming obsolete. The stockholder gets not only his regular return, he gets something additional. I noted, for example, that the income-tax division of the United States Treasury when the talkie made obsolete the old methods of production and the old methods of projecting movies, gave the industry the opportunity to write off more than it otherwise would of this obsolescence which suddenly came up it. In fact, the policy of business is to permit allowances not only for ordinary but also for extraordinary obsolescence of plant and machinery.

Certainly if it is the policy of industry, of our economy as a whole, to make the consumer pay for the obsolescence of the investment of the producer, society should be asked to bear the burden of the obsolescence that that very machine that makes other equipment obsolescent brings about in the case of the worker. And again I get back to what I said earlier, namely, I think we have had bad social bookkeeping, we haven't charged all of our costs of production. We have made certain people bear those costs of production, and in the case of technological changes it has been the worker or his family or his relatives or the public relief agencies.

Mr. PIKE. We have charged them but our allocation has been terrible.

Dr. LUBIN. We haven't charged them. Somebody paid for them but the people who got the benefit didn't pay.

Mr. PIKE. We haven't hit the right place.

Dr. ANDERSON. As a matter of fact, you wouldn't say that we had made any charge, that it was charged only in the sense of misery and poverty and deprivation. That is a definite social loss, but it doesn't appear in the bookkeeping.

Mr. PIKE. That is a big social charge.

Dr. LUBIN. Not only that, but workers' families and friends have paid part of the cost.

Dr. ANDERSON. That is true.

Dr. KREPS. In a sense the total cost, even when concentrated upon these workers, is larger than it would have been if we had diffused the cost of obsolescence to all the consumers, because it might well be that this perfectly valid cost charge would have tended to make

the introduction of some machines less speedy than would have been otherwise the case.

Dr. LUBIN. It might have in some instances; on the other hand, in other instances it might not have. But I want to come to that point in a minute, namely, what the results might be if we forced this burden upon those who really should bear it.

DISPLACEMENT COSTS CHARGEABLE TO SOCIETY

Dr. LUBIN. The question arises, then: how would you allocate this cost? One of the suggestions made to this committee by many witnesses was the dismissal wage. As you know, the dismissal wage is now in effect under voluntary arrangements in some instances and under collective agreements in other instances. I want to point out that the Congress of the United States, just as it has recognized the right of the investors to protect themselves against obsolescence in the income-tax law, has also recognized the equity of the principle providing for the displaced worker in the Railroad Transportation Act of 1933. Under that act, which makes specific provision for workers who are displaced as a result of railroad consolidation, an agreement was reached in 1936 whereby any worker who loses his job because of a merger of railroads, who has been employed for 15 years or over, is entitled to 5 years' pay on a basis of 60 percent of his average monthly earnings. In other words, we have undertaken to shift that cost from the employee who is displaced to the employer and thence to the consumer of the product. If he does not want to go on that sort of pension basis, he is entitled, if he has worked for more than 5 years, to a full year's pay, if he wants to withdraw from the industry. And we have gone even further. If as a result of consolidation a man has to move, the coordination plan provides that these workers be compensated for losses sustained by compulsory sale of their homes or other equities at less than fair value. So we protect not only their earning power but their capital losses. In other words, the principle, then, has already been accepted by the Congress of the United States in this consolidation law.

Not so very long ago in the case of the telephone and telegraph industry, when the Senate Committee on Interstate Commerce held hearings on a probable telephone and telegraph merger, that same suggestion was presented to the Congress. A merger will mean increasing the equity of the bondholder. At whose expense? The expense of 14,000 people who may lose their jobs. Of course, you are going to cut the cost of operation, you need fewer people when one company runs the system rather than two. It was recommended that for a certain number of years those savings in the equities of bondholders be shared with the workers; in other words, make provision for the workers over a series of years until they reach the retirement age, and only after they have been taken care of shall these increased equities and the values of the securities that arise out of this merger be given to the person who owned the equities.

Other cases were mentioned by various witnesses of similar attempts to handle the problem.

The question arises as to what the proper allocation of those costs might mean in terms of unemployment and technology as a whole.

I personally believe that the equitable allocation of these costs, the pooling of risk and some sort of insurance system, would, like the workmen's compensation system, not only tend to ameliorate the conditions of those who are displaced, it might even eliminate some of the causes.

We have found that the fact that workmen's compensation is charged to the cost of operation has led to cutting down accidents. In other words, it has made the employer conscious that he has to give consideration to the problem of his accidents, and similarly if he had to pay for displacement he would give more careful consideration to the problem of displacing labor. I think if he knew that it was going to cost him something he would be more careful in timing the introduction of his technological improvements. That may not necessarily delay improvements, it may even hasten them, if the employer tried to time this introduction to his labor turnover so he wouldn't displace people, that is time them to periods of increasing production when he is going to increase his employment. That has already been done by some employers, and some collective agreements like those of the Pressmen's Union, the Textile Workers' Union, and the Hosiery Workers' Union already have some provision for timing these changes so that they will bring with them the minimum suffering and displacement.

I think that the fact that the employer knows that the burden is being borne by him and his industry rather than by the worker himself will stimulate him to attempt to find jobs for displaced workers in his own plant, whereas now he doesn't care; it doesn't cost him anything, it doesn't cost the industry anything. I think that it will force him to retrain his workers, to seek some way of teaching them new jobs, so that his burden and the burden of his industry will be cut down. In other words, I think that such a system will not only shift the burden where it belongs, so that the hardship is no longer borne by the worker himself, but would, as I said a minute ago, tend toward elimination of the problem that we are trying to ameliorate through these dismissal wages.

Now, the question, of course, is as to how to cover these costs.

I recommend very definitely to this committee that it give careful consideration to the feasibility of a compulsory dismissal wage law to be tied up in some way or other with the unemployment-insurance system. I will admit that a voluntary system such as is now in effect in many plants would be an ideal way, or getting it through collective bargaining would be an ideal way, but the problem is too large, and I doubt whether we can wait that long.

Mr. PIRK. Isn't it also true, Dr. Lubin, that as brought out in the textile hearings the other day, in many of those industries that might need it most, where the problem is worst, the financial ability of the competing concerns is such that they couldn't do it unless it were put on all of them at once.

Dr. LUBIN. Exactly. Or let me put it this way, that the manufacturer himself, the employer himself, may be subject to the same forces that he may be technologically displaced by his competitor. Consequently it has got to be pooled.

Dr. ANDERSON. Do you include partial pooling as well as total pooling?

Dr. LUBIN. That is a question to be worked out. I don't want to go into the details. As I say, I think this is a question of experience. It took us a generation to iron out the knot in workmen's compensation. There is still controversy as to whether or not we should have a State system of unemployment compensation or a Federal system or a company system like Wisconsin has.

Dr. ANDERSON. It is more than a detail in this instance, I believe. The opposition to a universal dismissal wage would be tremendous, from a practical standpoint, were it to be a complete pool, on account of the variety of circumstances prevailing in the industry.

Dr. LUBIN. Well, those are administrative matters; I mean, how to determine whether a man has been displaced by a machine. And again I say, the only way you are going to solve the problem is to have to do it and deal with it. You have the problem, of course, as you probably know, in your own States, of certain boys at a university who went to work in the summer and their employers paid unemployment compensation benefits, and the boys went back to school in the winter, were not employed, but were drawing unemployment compensation while they were in school in the winter. Now, nobody foresaw that, but we are going to iron that out and find an answer to it; I mean, you are going to find that all the time.

Dr. ANDERSON. And you wouldn't make any distinction in dismissal wage procedure? You would take in all labor displacement regardless of cause?

Dr. LUBIN. I don't know. Frankly, I just couldn't answer that. I want to discuss the general idea. Now, I might point out that there are about 15 countries that have compulsory dismissal wages now. They apply to all dismissals. They make no distinction. Now, in a sense you have compulsory dismissal wages in the Unemployment Compensation Act. I mean, if a man loses his job, he is entitled to a certain number of weeks of compensation which, in a sense, is a dismissal wage, which they did not have before.

I feel definitely that the committee should give consideration to a compulsory dismissal wage, but with it should be tied up the whole problem of retraining and mobility; in other words, one of the conditions of receiving dismissal wage should be certain retraining programs, and if necessary, mobility, and it may be that that part of the dismissal wage might be used, for example, as in the railroads paying the cost of moving the family to another place where a job might be had.

My second recommendation is the extension of the benefit period under the Unemployment Compensation Act, again tied up with retraining and with mobility.

Such a system is going to create a lot of problems, but every new insurance idea, or pooling idea, is going to create a lot of problems. But I think that it is a direction in which we should look. I admit that during periods of large masses of unemployment the problem becomes much more difficult of administration than it would be when everybody was working; but that to me is no reason why we should not get moving in that direction now. If we can get started now, if another major depression occurs, we might have a working machine which will really cope with the problem of displacement even under such difficulties. If I might end these hearings in terms of a summary—our job would be, as I see it, to find a solution

of these problems within the framework and the pattern of private enterprise in our competitive system.

I think the solution can be found inside of that framework. In order to keep within that framework, however, I think that it is going to be our duty at all times to press to see to it that the system is kept flexible so that the mass markets can be exploited and more and more goods can be made available to more and more people; and incidentally, in keeping the system flexible, I want to make one point which may not appear very important and yet, to me, it is important.

As we discuss the question of the flexibility of the system and make these benefits of lower cost and technological improvements available to the man on the street, we stop ending our vigilance at the factory door.

In many instances, where costs are lowered by these methods, these lowered costs are reflected in lower wholesale prices, but the consumer never sees them. They are lost somewhere between the factory door and the consumer and if you are going to increase mass production, the consumer must get the lower price.

If I might conclude, Mr. Chairman, I would like to say that at least as I see the picture, power, invention, machinery, and efficiency have been the basis of the progress of the United States. They have made possible a continuous rise in our standards of living, and we should welcome more and more the application of science to methods of production and distribution.

At the same time, however, we must recognize that the application of science to industry is accompanied by certain social costs, frequently rather temporary which in the past have been borne by innocent victims. Our problem is today to allocate these costs so that all of us who benefit from scientific progress shall bear our equitable share.

The CHAIRMAN. Any questions?

COOPERATION OF EMPLOYMENT AGENCIES

Dr. ANDERSON. Dr. Lubin, I am sure you meant to include in your proposals, along with retraining and mobility and a dismissal wage, an integration also of employment agencies. The employment-service programs would have to be greatly enlarged, would they not, and integrated to provide complete coverage for agricultural, industrial, and other workers?

Dr. LUBIN. You would have to, if you were going to get any effective administration; in other words, I always like to think of the function of an administrative agency to be that of working itself out of a job. It ought to be there to eliminate the reasons for its being there. I think that the employment service would come in very effectively under that point.

Mr. PIKE. Dr. Lubin, I think you have gathered the feeling around here.

Dr. LUBIN. Well, I think the interest of the people here in these problems shows their awareness of them.

Mr. PIKE. No doubt, but you are trying to work yourself out of a job when you eliminate the function.

Dr. LUBIN. Well, the better you do it, the closer you come to eliminating the reason for your being there. I always felt that the National Labor Relations Board, if it ever gets to the point where it can bring about collective agreements, collective bargaining, has no

longer any reason for existence. It is only because you do not have collective bargaining that they are there.

Mr. PIKE. Yes; when you have accomplished that, the initial rush of administrative necessity is over.

Dr. LUBIN. That is right.

Mr. O'CONNELL. Of course, that would be less apt to be so in an area such as that covered by the Federal Trade Commission, because you would really have to change human nature before you could do that job.

Dr. LUBIN. Well, I agree that there would be exceptions of that sort.

The CHAIRMAN. Now, what about the criticism which is sometimes made that legislation of this kind unduly increases costs and thereby penalizes production?

Dr. LUBIN. Well, Mr. Chairman, there are definite data—I am sorry I have none available with me—which show the relationship between some of these burdens and costs. In virtually all instances, they have been insignificant in any particular product.

I don't think I am exaggerating when I say that in every instance where protection of dismissed workers has increased cost, it has also brought about decreases in costs in other instances because of the changed morale, the changed efficiency of labor that rises out of security.

The CHAIRMAN. Yes, you testified earlier in the afternoon with respect to instances that have come to your attention, of industries paying—or at least of manufacturers paying—50 percent more than the prevailing rate of wages and still maintaining a high competitive standard because of increased productivity.

Dr. LUBIN. Yes.

The CHAIRMAN. But is it not a fact that there is also a sort of psychological resistance against their suggestions of this kind?

Dr. LUBIN. Oh, I agree with you.

The CHAIRMAN. And based on this very ground?

Dr. LUBIN. Oh, yes; I will agree fully with you, and as a matter of fact, my contention is that this charge is being borne today and somebody is paying the cost of taking care of these people. The wrong people are paying the cost.

The CHAIRMAN. Yes; of course; the cost of taking care of the people now is being borne by the National Government in increased debt. It is perfectly obvious that the more we increase the debt, the greater the burden we place upon the future to pay the debt.

National debt, like any other debt, can be paid only out of production; so that you would agree that we must stimulate production in order to pay off the debt?

Mr. LUBIN. I will say that there is no answer to any of our problems without increasing production; in other words, increased production is the basis of greater distribution of goods, which means a higher standard of living, which in itself increases productivity.

The CHAIRMAN. National production and national income are practically synonymous, are they not?

Dr. LUBIN. Yes, except for changes in the price level.

The CHAIRMAN. And anything that contributes toward a reduction of production necessarily contributes to a reduction of national income, whether that factor is a monopolistic practice by industry, or

increased national debt, for example, or inefficient application of relief, to the unemployment problem?

Dr. LUBIN. That is true.

The CHAIRMAN. Then I suppose you would agree that the measure of tax revenue is the measure of production?

Dr. LUBIN. Yes. If tax rates remain unchanged.

The CHAIRMAN. If we can stimulate production, we necessarily increase revenue.

Dr. LUBIN. With the same rates you automatically increase it.

The CHAIRMAN. That is right. Well, do you think there would be any virtue in attempting to stimulate employment and thereby increasing the available consuming power by tax rewards to those who employ labor?

Dr. LUBIN. Well, it depends entirely what sort of tax reward you have. Let me give you a concrete illustration of what I mean; I think there is some logic, although I have been told by those who know the tax system, that the administrative problem would be very difficult, in giving a tax reward to a man who increases both his production and his employment. You might increase employment by this device but you might not necessarily increase production. You might find yourself with no addition to the national income.

The CHAIRMAN (interposing). Well, the net addition might not be made by that particular producer or that particular employer, but the increased purchasing ability or capacity of the worker who is given the job would reflect itself in increased demand for the product of some other industry.

Dr. LUBIN. That assumes, however, that the funds used to take care of the worker who has been added to the staff would not have been used in some other way. In other words, if a man is receiving \$50 a month from W. P. A. and you take him off of W. P. A. and put him into a private job and you have not at the same time increased the net production of the country, you have made no increase in the national income.

In other words, what I am getting at is this, that all you may have is a shift from the Government supporting a displaced worker to the employer supporting him, so the net gain in purchasing power may not be changed. If, on the other hand, in the process of doing it, he produced more goods, so the country as a whole would be better off, I would say we would benefit.

The CHAIRMAN. Are there any other questions? Well, then this brings our hearing regretfully to a close.

Dr. ANDERSON. Mr. Chairman, what we have tried to do in the last 3 weeks, I think, has been well summarized by the two witnesses of the afternoon.

We started 3 weeks ago with a statement of a general character by Dr. Kreps, which took the positive position that this America of ours had an unlimited internal frontier, that we can do much more than we have done, that our present unemployment, involved and difficult as it is to solve, can and must be solved if our private economy is to continue. From that first statement we moved to an outline of the prospects of the immediate future, and gave the areas of technological change which might give us the expansion necessary to provide full employment of our labor force.

On successive days we presented industries which were in themselves large employers of labor, and in which technological changes

(using "technological" in a broad sense to encompass the five points that Mr. Lubin has enumerated) were large and paramount features of a substantial labor displacement.

Yesterday we began an analysis of what could be done about it. Educational people discussed the possibilities of vocational training and placement, and retraining and replacement of the displaced laborers, and today we have had a summary by Mr. Gill, of the National Research Project, which forms the largest, most comprehensive available analysis of the effect of technology upon labor. Now, finally, this brilliant statement of Dr. Lubin's summarizes and brings to a close the 3 weeks of hearings.

Following this, the technical staff will offer the committee certain analyses for its deliberations and conclusions.

The CHAIRMAN. I beg your pardon? I didn't get that last statement. I want to know what is in store for us.

Dr. ANDERSON. We have collected a body of material, much of which is before you and in your files. There is also much yet to come which must be summarized and brought to the committee's attention for its deliberations. That is what I meant by that last statement.

The CHAIRMAN. The interesting factor in this whole story to me has been the practical unanimity of all witnesses, whether they came from the employer side or the employee side, that there is an unemployment problem and that although the advance of science, invention, and technology does create new problems and new industries, there is a displacement of particular persons and a lack of opportunity for employment as a result.

It was also a striking thing to me that almost every person who testified protested that he was offering no panacea, no cure for it all, and even though Dr. Lubin has made a recommendation, he has also qualified that by saying that he does not believe that one solution will solve the whole problem. It is unquestionably a matter of the gravest importance, and one which not only the committee but all people in the country should give a little more thought to than, apparently, was given to the report of Senator Couzens' committee in 1929, when the problem was diagnosed. We are still waiting for a cure.

Dr. LUBIN. I am very sensitive about that, Mr. Chairman, because I was the economic adviser of that committee.

The CHAIRMAN. The States which were represented by the Committee on Education and Labor, which authorized this report, perhaps deserve mention, since they share part of the credit: Michigan, Idaho, Colorado, Rhode Island, Connecticut, Massachusetts, New York, Tennessee, Ohio, and Texas. It was a pretty broad representation of the country.

The committee is very much indebted to you, Dr. Lubin, for this statement this afternoon.

I cannot declare an adjournment without complimenting Dr. Anderson for the excellent manner in which the evidence has been presented, and Dr. Kreps for his participation.

Perhaps I should also mention that Mr. Pike and Mr. O'Connell were conspicuous for their consistent record of attendance.

(Whereupon, at 5:30 in the afternoon, the committee adjourned, subject to call of the Chair.)

APPENDIX

EXHIBIT No. 2428

[Submitted by the Temporary National Economic Committee Study Staff]

Below are listed only those innovations, mostly inventions, which have been of major direct importance for modern industry. For example, no medical discoveries are listed at all despite their undisputed significance.

The increase in the pace of invention appears clearly in this Exhibit. Note that some of the most important inventions were made in prehistoric time. Those unknown inventors who domesticated fire and found out how to treat metals who tamed the wild animals of the field and forest to draw their plows and transport their burdens rank among the greatest inventors of all human history. Nothing that we did from 1750 to 1930 in the improvement of the cereal grasses, for example, has approached the accomplishment of prehistoric man in increasing the amount of wheat and corn and the like yielded by the original grasses with which he began. Our debt to the unknown inventors of all ages can hardly be fully appreciated.

Moreover, many of the inventions most fundamental to human well-being came into being long before we had devised large corporations or patent systems or university and industrial research laboratories or technical schools and other paraphernalia often thought by those unacquainted with history to be fundamental prerequisites to the birth and development of a new idea. Leonardo da Vinci, for example, one of the greatest scientists as well as artists of his day, was instrumental in giving modern industry the centrifugal pump, the dredge for canal building, the anti-friction roller bearing, the universal joint, the conical screw, the rope-and-belt drive, link chains, bevel gears, spiral gears, proportional and paraboloid compasses.

Advances in medicine have been fully as rapid as those in industry, yet owe almost nothing to economic institutions or individual desire for wealth. Because inventions depend on science they are predictable. On this point a chapter written by Dr. S. C. Gilfillan entitled "The Prediction of Inventions" in the well-known study entitled *Technological Trends and National Policy* published by the National Resources Committee in June 1937 gives conclusive proof. Among the interesting examples cited is that published in the *Scientific American* of October 1920 when a long editorial article entitled "The Future as Suggested by the Developments of the Past 75 Years" made predictions concerning the inventions that would occur during the next 20 years. Of these 78 percent have been verified.

If one is familiar with what has happened in the world of science, one can predict what is going to happen in industry. For it takes time for that which has been found out by the scientists to be known and applied in industry. "Television began to be invented in 1877, picture telegraphy about 88 years before it attained important use, * * * radio telephony 23 years, the airplane 70 or more and the talking picture 40 years, before they had any importance."

Other notable examples are: the electric furnace, of arc and incandescent types, first working model in 1810, beginning of modern commercial practice, 1886; nitrogen fixation, 1785 and 1900-1903; calcium carbide, 1862 and 1895; petroleum cracking, 1860 and 1908-1914; mechanical firing of boilers, 1800 and 1845; the caterpillar tread, 1770 and 1904; the combined harvester and thresher, 1828 and 1886; the milking machine, 1819 and 1905; the moving picture, 1859 and 1892; the typewriter, 1714 and 1873.

Says Dr. Gilfillan on this point:

"Taking 19 inventions voted most useful, introduced in 1888-1913, the average intervals were: Between when the inventions was first merely thought of, and the first working model or patent, 176 years; thence to the first practical use, 24 years; to commercial success 14 years; to important use 12 years, or say 50 years from the first serious work on the invention. Again in the study of the most important inventions of the last generation before 1930, in *Recent Social Trends* (written

by President Hoover's Committee), a median lapse was found of 33 years between the 'conception date' * * * and the date of commercial success."

Inventions, in short, have causes. As Dr. Gilfillan says:

"They are not just accidents, nor the inscrutable products of sporadic genius, but have abundant and clear causes in prior scientific and technological development. And they have social causes and retarding factors, both new and constant, of changed needs and opportunities, growth of technical education, of buying power, of capital, patent and commercial systems, corporation laboratories, and what not."

The fact that scientific knowledge brings about invention after a period of time also accounts for the fact that the same invention is so frequently made at the same time by individuals unknown to each other and widely separated geographically and industrially. To cite one or two well-known examples: alizarin was discovered in the same year by Graebe and Liebermann in Germany, without benefit of patent system, and by Perkins in England, where a patent system had been in operation since 1634. Similar simultaneity characterized the invention of the process of extracting aluminum from bauxite by Hall in the United States and Heroult in France; the telephone in 1876 by Bell and Gray; and the telegraph in the period from 1831-1837 by Henry, Morse, Cooke, Wheatstone and Steinheil. In fact, in a book entitled "*Social Change with respect to Culture and Original Nature*," W. F. Ogburn gives a list comprising 13 pages of inventions made simultaneously. If additional evidence is required, one need only look at the voluminous court record of patent cases involving disputes over claims of priority.

LIST OF INVENTIONS

Summary of the existing technics before the tenth century.—Fire: its application in furnaces, ovens, kilns. The simple machines: inclined plane, screw, etc. Thread, cord, rope. Spinning and weaving. Advanced agriculture, including irrigation, terrace-cultivation, and soil regeneration (lapsed in Northern Europe). Cattle breeding and the use of the horse for transport. Glass-making, pottery-making, basket-making. Mining, metallurgy and smithing, including the working of iron. Power machines: water-mills, boats with sails, probably windmills. Machine-tools: bow-drills and lathes. Handicraft tools with tempered metal cutting edges. Paper. Water-clocks. Astronomy, mathematics, physics, and the tradition of science. In Northern Europe a scattered and somewhat decayed technological tradition based on Rome; but South and East, from Spain to China, an advanced and still active technology, whose ideas were filtering into the West and North through traders, scholars, and soldiers.

TENTH CENTURY

Use of water-clocks and water-mills. The iron horse-shoe and an effective harness for horses. Multiple yoke for oxen. Possible invention of the mechanical clock.
999: Painted glass windows in England.

ELEVENTH CENTURY

1041-49: Movable type (Pi Sheng).
1050: First real lenses (Alhazen).
1065: Oliver of Malmesbury attempts flight.
1080: Decimal system (Azachel).

TWELFTH CENTURY

Military use of gunpowder in China. The magnetic compass, known to the Chinese 1160 B. C., comes into Europe, via the Arabs.
1100: Bologna University.
1105: First recorded windmill in Europe (France).
1118: Cannon used by Moors.
1144: Paper (Spain).
1147: Use of wood cuts for Capital letters. (Benedictine monastery at Engelberg).
1180: Fixed steering rudder.
1188: Bridge at Avignon. 18 stone arches—3,000 ft. long.
1190: Paper mill (at Herault, France).
1195: Magnetic compass in Europe (English Citation).

THIRTEENTH CENTURY

- Mechanical clocks invented.
 1232: Hot-air balloons (in China).
 1247: Cannon used in defence of Seville.
 1269: Pivoted magnetic compass (Petrus Peregrinus).
 1270:
 Treatise on lenses (Vitellio).
 Compound lenses (Roger Bacon).
 1272: Silk reeling machine (Bologna).
 1280: Opus Ruralium Commodorum—Compendium of Agricultural Practice (Petrus de Crescentis).
 1285-1299: Spectacles.
 1289: Block printing (Ravenna).
 1290: Paper mill (Ravensburg).
 1298: Spinning wheel.

FOURTEENTH CENTURY

- Mechanical clock becomes common. Water-power used to create draft for blast furnace; makes cast-iron possible. Treadle loom (inventor unknown). Invention of rudder and beginning of canalization. Improved glass-making.
 1300: Wooden type (Turkestan).
 1315: Beginnings of Scientific Anatomy through dissection of human body (Raimondo de Luzzi of Bologna).
 1320: Water-driven iron works, near Dobilugk.
 1322: Sawmill at Augsburg.
 1324: Cannon (Gunpowder: 846 A. D. (Magnus Graecus)].
 1330: Crane at Luneburg.
 1338: Guns.
 1345: Division of hours and minutes into sixties.
 1350: Wire-pulling machine (Rudolph of Nurnberg).
 1370: Perfected mechanical clock (von Wyck).
 1382: Giant cannon—4.86 metres long.
 1390: Metal types (Korea).
 1390: Paper mill.

FIFTEENTH CENTURY

- Use of wind-mill for land drainage. Invention of turret windmill. Introduction of knitting. Iron drill for boring cannon. Trip-hammer. Two-masted and three-masted ship.
 1402: Oil painting (Bros. van Eyck).
 1405: Diving suit (Konrad Kyeser von Eichstadt).
 1405: Infernal machine (Konrad Kyeser von Eichstadt).
 1409: First book in movable type (Korea).
 1410: Paddle-wheel boat designed.
 1418: Authentic wood engraving.
 1420: Observatory at Samarkand.
 1420: Sawmill at Madeira.
 1420: Velocipede (Fontana).
 1420: War-wagon (Fontana).
 1423: First European woodcut
 1430: Turret windmill.
 1436: Scientific cartography (Banco).
 1438: Wind-turbine (Mariano).
 1440: Laws of perspective (Alberti).
 1446: Copperplate engraving.
 1440-1460: Modern printing (Gutenberg and Schoeffer).
 1457: Rediscovery of wagon on springs referred to by Homer.
 1470: Foundations of trigonometry (J. Muller Regiomontanus).
 1471: Iron cannon balls.
 1472: Observatory at Nurnberg by Bernard Walther.
 1472-1519: Leonardo da Vinci made the following inventions:
 Centrifugal pump.
 Dredge for canal-building.
 Polygonal fortress with outworks.
 Breech-loading cannon.
 Rifled firearms.
 Antifriction roller bearing.

There are two other psychiatrists, of whom I know something, who are interested in this point of view. One is Dr. Douglas C. Campbell, who is leaving Chicago to take up work in California. The other is Dr. Temple Burling, of R. H. Macy & Company, New York City.

Third, economics. I can illustrate an identical point of view by quoting briefly from a book entitled *An Essay on the Nature & Significance of Economic Science*, by Lionel Robbins, Professor of Economics in the University of London. On page 98 he says that from the point of view of pure Economics the demand for commodities is conditioned on the one side by individual valuations and on the other side by the technical facts of the given situation. He goes on to discuss whether one can scientifically investigate individual valuations, and in this regard he at once makes the statement, " * * * we are here entering upon a field of investigation where there is no reason to suppose that uniformities are to be discovered." The reply to this observation is twofold. In the first place, I do not suppose that any scientific investigation has ever been certain that there are uniformities to be discovered before the investigation begins. Science has always made the assumption that there are such uniformities if an inquiry is rightly conducted, and the assumption has not yet been disappointed. Second, these uniformities have been discovered, though not by the economists. It is these uniformities, imposed by the informal groups upon the members conditioned to a particular way of living, that we have been studying for fourteen years. It is true that Mr. Robbins and the economists have not discovered the uniformities which are actually there, but this fact implies nothing but neglect on their part.

II. EXECUTIVE AUTHORITY

This subject has been discussed admirably by Mr. Chester I. Barnard in his book *The Functions of the Executive* (Harvard University Press, 1938). This book is based upon his own experiences as President of the New Jersey Bell Telephone Company. But although I regard knowledge of Mr. Barnard's work as a necessary preparation for the research that is required, I do not regard his book as doing more than mapping out the country and indicating where exploration is gravely needed. In this connection I should like to point out that every department of government or political science in the universities of this country discusses the exercise of executive authority, whether politically or in industry, as if government were a one-phase system, capable of being set out thus as a blueprint plan. This inadequacy to the actual facts of democracy and executive control puts our political theorists into a very awkward position with respect to the exponents of authoritarian systems, such as Fascism and Communism, for it makes it seem that the only difference between democratic and Fascist authority is the inferiority in respect both of intelligence and action of democratic systems. In other words, there is no government department in the country which has even begun the appropriate research into, or is capable of explaining, the superiority of democracy to absolutist systems.

The fact is that democracy is a two-phase (perhaps multi-phase) system. In any society, authority originates mainly in the spontaneous co-operation of the people who constitute the society. That is to say, it originates in the informal group associations of which I have been speaking. In a complex society, no matter where, this spontaneous co-operation still originates in the informal associations at the working bench, but the formal, logical, and purposive authority, the organization plan and control, originates at the executive head. This, then, gives the two-phase aspect of democracy logical and critical control from above, spontaneous and co-operative control from below. Democracy, therefore, is at least a two-phase system. In ordinary times it is important that any authoritative reordering of the group should proceed from the lower level of spontaneous co-operation. In exceptional times, in times of emergency, it is necessary that the central authority should take over an almost absolute control for the period of the emergency. Democracy, then, is a two-phase system in that in times of emergency the central control is strengthened; when the emergency is past the control is automatically passed again in some degree to the peripheral organizations. This fact has not ever been adequately studied or documented. It is, nevertheless, crudely represented in the elective systems of the great democracies. The periodic election is at least symbolic of the passing of the control to the peripheral organizations. The period between elections is symbolic of the vesting of control in the logical and purposive executive.

I have two young men who have been trained and who wish to make this study. At present we lack funds to do it. I have no knowledge of any such study elsewhere.

III. UNEMPLOYMENT

The usual method of studying unemployment, which can be illustrated either here or in England, is first to find out and express statistically, as accurately as may be, the number of unemployed. Second, a study is made of so-called depressed areas and of the morale of individuals in them. Third, an attempt is made by means of civilian camps or resettlement or training in new trades to start some of the unemployed again in work. I should like to point out that, excellent as this is, it is no more than the intensive study of a symptom and includes no attempt whatever to diagnose the ill. Yet it is possible to take account of work done many years ago in France (and some work here) and to see, however dimly, the nature of the ill that so urgently demands diagnosis. First, one must study the people who are employed rather than merely the unemployed. Palliatives are excellent but the disease demands specific treatment. In the last century, Durkheim pointed out that during prosperity the informally organized ways of living that had developed historically in a society were apt to be adversely affected. And he showed that this is specially true of modern industrial societies. It is not only the rapid movement from place to place which disrupts the ordered way of living, it is also the rapid change in the type of house and the type of relationship between families in a neighborhood. Whereas in simpler times a neighborhood unit was a real entity, in the modern industrial center, on the contrary it is largely inhabited by a floating population which has no time or opportunity to develop a common and neighborhood way of living. The effect of this upon the standard of living is disastrous. Economists are accustomed to consider the phrase "standard of living" as if it were satisfactorily accounted for by examining the amount of money spent, or available for spending, by individuals. While this does give actual expenditures and may be of interest to those who study demand, it gives practically no information about *standard* of living. A standard of living is once again a group determination. There is stability of demand for those commodities which an informal group has decided are necessary to the social group life. Such a group, even when its income is gravely diminished, will not willingly abandon the purchase of those commodities which to them are necessary for the maintenance of social relationships with their acquaintances and friends. Now, as Durkheim has pointed out, in times of rapid social movement, in times of chaos and social disintegration, these standards suffer severe damage. If people cease to be members of a group, they no longer have actual need of those material possessions which are necessary to the group amenities. Consequently, those material goods which formerly were necessities for a people become merely luxuries, the purchase of which can be instantly abandoned in any period of "depression." For example, when we lived in small communities, a marriage at almost any level required of those marrying that they should possess household linen and household silverware of some kind. In these recent times of rapid movement (and social impoverishment of living) the demand for these goods has fallen rapidly. They have ceased to be necessities and have become luxuries that few people can afford. All that a marriage requires in these days is a single apartment and a few cocktail glasses. This is social impoverishment of the most serious kind and a definite degradation of the standard of living which infallibly shows itself in a diminished stability of demand for almost all civilized commodities.

If one reads such a book as Schumpeter's recently published *Business Cycles* one sees that a claim can be made for American capitalism. Only American capitalism can claim to be a system which has progressively raised the standard of living of [the working group; This is indeed the chief character of] North American civilization. It is, however, unfortunately true that in the process of continuously raising the standard of living American civilization has unwittingly destroyed all *standards* of living, i. e. social disintegration has converted necessities back to luxuries—the "ways of living" have deteriorated. The resulting ills are an incredible instability of demand for almost anything, with embarrassingly wide fluctuations according to the popular estimate of the present and future and, as a consequence very largely of this, unemployment.

So far as I know this study, which is cardinal to the diagnosis of the social disequilibrium which we call unemployment, is not actually in process anywhere. Here again it is perfectly obvious that the assumption made by psychologists, psychiatrists, and economists, that society is no more than a horde of individuals, must be thrown overboard, and as speedily as possible a direct study of informal group organization substituted for the gratuitous and unwarranted assumption.

This is the best that I can do for you by way of statement at short notice. You ask me at the end of your telegram not only where we badly need to institute and develop researches, but who in my opinion are the leading investigators in

- Universal joint.
- Conical screw.
- Rope-and-belt drive.
- Link chains.
- Submarine-boat.
- Bevel gears.
- Spiral gears.
- Proportional and paraboloid.
- Compasses.
- Silk doubling and winding apparatus.
- Spindle and flyer.
- Parachute.
- Lamp-chimney.
- Ship's log.
- Standardized mass-production house.
- 1481: Canal lock (Dionisio and Petro Domenico).
- 1483: Copper etching (Wenceslaus von Olnutz).
- 1492: First globe (Martin Behaim).

SIXTEENTH CENTURY

- Tinning for preservation of iron. Windmills of 10 H. P. become common. Much technical progress and mechanization in mining industries, spread of blast-furnaces and iron-moulding. Introduction of domestic clock.
- 1500: Mechanical farming drill (Cavallina).
 - 1518: Fire-engine (Platner).
 - 1530: Foot-driven spinning wheel (Jurgens).
 - 1534: Paddle-wheel boat (Blasco de Garay).
 - 1546: Railway in German mines.
 - 1548: Water supply by pumping works (Augsburg).
 - 1550: First known suspension bridge in Europe (Palladio).
 - 1558: Military tank.
 - 1558: Camera with lens and stop for diaphragm (Daniello Barbaro).
 - 1565: Lead pencil (Gesner).
 - 1578: Screw lathe (Jacques Besson).
 - 1579: Automatic ribbon loom at Dantzig.
 - 1589: Knitting frame (William Lee).
 - 1590: Compound microscope (Jansen).
 - 1595: Wind-turbine (Veranzio).

SEVENTEENTH CENTURY

- Water wheels of 20 H. P. introduced: transmission by means of reciprocating rods over distance of one-quarter mile. Glass hothouse comes into use. Foundations of modern scientific method. Rapid developments in physics.
- 1613: Gunpowder in mine blasting.
 - 1618: Machine for plowing, manuring and sowing (Ramsay and Wilgoose).
 - 1620: Adding machine (Napier).
 - 1624: Submarine (Cornelius Drebbel). Went two miles in test between Westminster and Greenwich.
 - 1624: First patent law protecting inventions (England).
 - 1628: Steam engine (described 1663 by Worcester).
 - 1636: Fountain pen (Schwenter).
 - 1636: Threshing machine (Van Berg).
 - 1650: Calculating machine (Pascal).
 - 1652: Air pump (v. Guericke).
 - 1665: Steam automobile model (Verbiest, S. J.).
 - 1669: Seed drill (Worlidge).
 - 1678: Power loom (De Gennea).
 - 1680: First power dredge (Cornelius Meyer).
 - 1688: Distillation of gas from coal (Clayton).

EIGHTEENTH CENTURY

- Rapid improvements in mining and textile machinery. Foundation of modern chemistry.
- 1700: Water power for mass-production (Polhem).
 - 1709: Coke used in blast furnace (Darby).
 - 1711: Sewing machine (De Camus).

- 1714: Mercury thermometer (Fahrenheit).
 1714: Typewriter (Henry Mill).
 1727: Light-images with silver nitrate (Schulze: see 1839).
 1730: Stereotyping process (Goldsmith).
 1733: Flying shuttle (Kay).
 1733: Roller spinning (Wyatt and Paul).
 1736: Commercial manufacture of sulphuric acid (Ward).
 1738: Cast-iron rail tramway (at Whitehaven, England).
 1755: Iron wheels for coal cars.
 1756: Cement manufacture (Smeaton).
 1763: Modern type chronometer (Le Roy).
 1765-1769: Improved steam pumping engine with separate condenser (Watt).
 1767: Spinning jenny (Hargreaves).
 1769: Steam carriage (Cugnot).
 1774: Boring machine (Wilkinson).
 1776: Reverberatory furnace (Brothers Cranege).
 1778: Modern water closet (Bramah).
 1778: Talking automaton (von Kempelen).
 1781-1786: Steam engine as prime mover (Watt).
 1781: Steamboat (Jouffroy).
 1782: Balloon (J. M. and J. E. Montgolfier). Original invention Chinese.
 1784: Puddling process—reverberatory furnace (Cort).
 1784: Spinning mule (Crompton).
 1785: Interchangeable parts for muskets (Le Blanc).
 1785: Power loom (Cartwright).
 1785: Chlorine as bleaching agent (Berthollet).
 1785: Screw propeller (Bramah).
 1787: Screw propeller steamboat (Fitch).
 1788: Threshing machine (Meikle).
 1790: Manufacture of soda from NaCl (Le Blanc).
 1790: Sewing machine first patented (M. Saint—England).
 1791: Gas engine (Barker).
 1792: Gas for domestic lighting (Murdock).
 1793: Cotton gin (Whitney).
 1793: Signal telegraph (Claude Chappe).
 1795-1809: Food-canning (Appert).
 1796: Lithography (Senefelder).
 1796: Hydraulic press (Bramah).
 1797: Screw-cutting lathe (Maudslay).
 Improved slide-rest metal lathe (Maudslay).
 1799: Manufactured bleaching powder (Tennant).

NINETEENTH CENTURY

- Enormous gains in power conversion. Mass-production of textiles, iron, steel, machinery. Railway building era. Foundations of modern biology and sociology.
- 1801: Public railroad with horsepower—Wandsworth to Croydon, England.
 1801: Steamboat *Charlotte Dundas* (Symington).
 1801-1802: Steam carriage (Trevithick).
 1802: Planing machine (Bramah).
 1804: Jacquard loom for figured fabrics.
 1805: Twin screw propeller (Stevens).
 1807: First patent for gas-driven automobile (Issac de Rivaz).
 1807: Kymograph—moving cylinder for recording continuous movement (Young).
 1813: Power loom (Horrocks).
 1820: Incandescent lamp (De la Rue).
 1822: Steel alloys (Faraday).
 1824: Portland cement (Aspdin).
 1825: Stockton and Darlington Railway.
 1826: Reaping machine (Bell). First used in Rome and described by Pliny.
 1827: High pressure steam boiler—1,400 lbs. (Jacob Perkins).
 1827: Chromo-lithography (Zahn).
 1828: Machine-made steel pen (Gillot).
 1829: Filtration plant for water (Chelsea Water Works, London).
 1830: Compressed air for sinking shafts and tunnels under water (Thomas Cochrane).

- 1830: Elevators (used in factories).
1831: Dynamo (Faraday).
1833: Magnetic telegraph (Gauss and Weber).
1834: Anilin dye in coal tar (Runge).
1834: Workable liquid refrigerating machine (Jacob Perkins).
1835: Electric automobile (Davenport).
1836: First application of electric telegraph to railroads (Robert Stephenson).
1837: Needle telegraph (Wheatstone).
1838: Electro-magnetic telegraph (Morse).
1838: Steam drop hammer (Nasmyth).
1838: Two-cycle double-acting gas engine (Barnett).
1838: Propeller steamship (Ericsson; see 1805).
1838: Boat driven by electric motor (Jacobi).
1839: Manganese steel (Heath).
1839: Daguerreotype (Niepce and Daguerre).
1839: Hot vulcanization of rubber (Goodyear).
1840: First steel cable suspension bridge, Pittsburgh (Roebing).
1843: Typewriter (Thurber).
1843: Gutta serena (Montgomery).
1844: Practical wood-pulp paper (Keller).
1844: Cork-and-rubber linoleum (Galloway).
1845: Modern high speed sewing machine (Elias Howe).
1845: Pneumatic tire (Thomson).
1845: Mechanical boiler-stoker.
1846: Nitroglycerine (Sobrero).
1848: Modern safety match (R. C. Bottger).
1851: Electro-magnetic clock (Shepherd).
1851: Reaper (McCormick).
1853: Great Eastern steamship—680 feet long—watertight compartments.
[1854: Automatic telegraph message recorder (Hughes)].
1855: Commercial production of aluminum (Deville).
1855: Television (Caselle).
1855: Safety lock (Yale).
1856: Open hearth furnace (Siemens).
1856: Bessemer converter (Bessemer).
1859: Oil mining by digging and drilling (Drake).
1860: Ammonia refrigeration (Carre).
1860: Asphalt paving.
1861-1864: Dynamo motor (Pacinotti).
1863: Ammonia soda process (Solvay).
1864: Motion picture (Ducos).
1865: The lead storage battery.
1866: Practical dynamo (Siemens).
1867: Dynamite (Nobel).
1867: Typewriter (Scholes).
1867: Two-wheeled bicycle (Michaux).
1868: Tungsten steel (Mushet).
1869-1872: Ball and roller bearings, the air brake.
1870: Electric steel furnace (Siemens).
1870: Artificial madder dye (Perkin).
1872: Automatic airbrake (Westinghouse).
1873: Ammonia compression refrigerator—Carle Linde (Munich).
1874: Steamed-lined locomotive.
1876: Electric telephone (Bell).
1876: The cigarette machine.
1877: Microphone (Edison).
1877: Phonograph (Edison).
1878: Centrifugal cream separator (De Laval).
1879: Carbon glow lamp (Edison).
1879: Cash register.
1880: Electric elevator (Siemens).
1880-1887: The automobile.
1882: First central power station (Edison).
1882: Motion picture camera (Marly).
1882: Steam turbine (De Laval).
1883: High speed gasoline engine (Daimler).
1884: Steel-frame skyscraper (Chicago).
1884: Linotype (Mergenthaler).

- 1884: Steam turbine (Parsons).
- 1886: Aluminum by electrolytic process (Hall).
- 1886: Hand camera (Eastman).
- 1886: Electric fan.
- 1887: Polyphase alternator (Tesla).
- 1888: Recording adding machine (Burroughs).
- 1888: Cyanide process for gold and silver.
- 1889: Artificial silk of cotton refuse (Chardonnet).
- 1889: Modern motion picture camera (Edison).
- 1890: Pneumatic tires on bicycles.
- 1891: Trinitrotoluol.
- 1892: Calcium carbide (Willson and Moissan).
- 1893-1898: Diesel motor.
- 1893: By-product coke oven (Hoffman).
- 1895: Motion picture projector (Edison).
- 1895: X-ray (Roentgen).
- 1895-1897: Liquid oxygen.
- 1896: Steam-driven aerodrome flight—one-half mile without passenger (Langley).
- 1896: Radio-telegraph (Marconi).
- 1898: Radium (Curie).
- 1899: Loading coil for long distance telegraphy and telephony (Pupin).

TWENTIETH CENTURY

General introduction of scientific and technical research laboratories.

- 1900: High speed tool steel (Taylor & White).
- 1900: Nernst lamp.
- 1902: Radial type airplane engine (Charles Manly).
- 1902: Hydrogenation of oils.
- 1903: First man-lifting airplane (Orville and Wilbur Wright).
- 1903: Arc process nitrogen fixation (Birkeland and Eyde).
- 1903: Oil-burning steamer.
- 1903: Tantalum lamp (von Bolton).
- 1903: Flotation process for non-ferrous metals.
- 1905: Cyanamide process for nitrogen fixation (Rothe).
- 1905: Domestic electric washing machine.
- 1906: Synthetic resins (Bakeland).
- 1906: Audion (De Forest).
- 1907: Automatic bottle machine (Owen).
- 1907: Tungsten lamp.
- 1907: Television-photograph (Korn).
- 1907: Multiple disk clutch.
- 1909: Duralumin (Wilm).
- 1910: Gyro-compass (Sperry).
- 1910: Synthetic ammonia process for nitrogen fixation (Haber).
- 1913: Tungsten filament light (Coolidge).
- 1917: Mechanical refrigerator.
- 1920: Radio broadcasting.
- 1922: Perfected color-organ (Wilfred).
- 1924: Quick drying, colorful varnishes.
- 1927: Radio television.

EMPLOYMENT CREATED BY NEW MANUFACTURING INDUSTRIES

The importance of new industries, which are being constantly created and developed by advancement in science, invention, and technology as sources of new opportunities for employment of labor, is shown in the following table. There it appears that 18 new manufacturing industries alone, which came into existence since 1879, absorbed almost one-seventh of all the labor employed in manufacturing in 1929.

Wage earners in 18 new manufacturing industries since 1879

[Source: Census of Manufactures]

Industry	Average Number of Wage Earners 1929
Electrical machinery, apparatus, and supplies.....	328, 722
Motor vehicles, not including motorcycles.....	228, 116
Motor vehicle bodies and parts.....	221, 332

Productivity, Output, and Employment—Percentage Changes between Designated Years

I. IN MAJOR GROUPS OF INDUSTRIES

A. FROM 1923-24 TO 1936-37

Item	Manu- facturing	Mining	Rail- roads	Electric Light and Power
Productivity.....	+50	+89	+43	+111
Physical volume of output.....	+25	+12	-17	+141
Man-hours of employment.....	-16	-41	-42	+14
Number of wage earners.....	+3.5	-14	-39	+36

B. FROM 1923-24 TO 1928-29

Productivity.....	+25	+32	+16	+31
Physical volume of output.....	+27	+16	+5	+71
Man-hours of employment.....	+1.8	-13	-10	+31
Number of wage earners.....	+2.8	-5.8	-9	+41

II. IN SELECTED MANUFACTURING INDUSTRIES

A. FROM 1923-24 TO 1936-37

Item	Auto- mobiles and Parts	Iron and Steel	Paper and Pulp	Cotton Tex- tiles	Tobac- co
Productivity.....	+47	+56	+52	+39	+140
Physical volume of output.....	+46	+16	+50	+7	+17
Man-hours of employment.....	-0.7	-25	-1.5	-24	-51
Number of wage earners.....	+25	-1	+12	-7	-35

B. FROM 1923-24 TO 1928-29

Productivity.....	+31	+35	+22	+2.8	+32
Physical volume of output.....	+50	+30	+31	+5.3	+11
Man-hours of employment.....	+15	-3.5	+7	+2.4	-16
Number of wage earners.....	+13	-4.3	+5	-3.8	-15

Source: National Research Project, Works Progress Administration, Philadelphia, Pa., 1939.

The National Research Project collected data from various sources showing the production, employment, and productivity in 59 industries, employing more than 50 per cent of all workers in manufacturing. Some of the series run from 1913 to 1937, others are complete for shorter time spans. In the summary table compiled from these data, 1929 is used as a base, and in all except a few cases the comparison is made between 1936 and that date. Thus, the series is three or more years old, a significant fact, in view of technological changes made since 1936. For example, the most abrupt changes in steel occurred after 1937, with the result that while in September, 1939, steel production was only 1.3 per cent below the comparable month in 1937, workers engaged in that production had decreased 16.0 per cent.

Production.—In the series 67 industries, or branches of industries, are represented. Of that number, 23 showed appreciable gains in production in 1936 as compared with 1929; 3 maintained production at approximately the same levels; and 40 had curtailed production below 1929 levels. The largest production increase was experienced in the rayon industry, which in 1937 had an index of 281.5. The greatest loss in production was shown in beehive coke, which had declined in 1935 to 26.1 per cent of 1929.

When the products of the 67 industries or branches are divided into durable and non-durable categories, it appears that 17 are producing durable goods and 48 non-durable. Only one of the durable goods industries showed an increase in output in 1936 over 1929, while 16 showed losses. Among non-durable goods industries, on the other hand, 24 made gains in production, 3 remained stationary, and 21 experienced declines. Of the ten food industries represented, 5 showed increases in production, 1 remained stationary, and 4 suffered actual declines. Of the 9 clothing industries, 7 had increased production, while 2 had fallen off in 1936 in comparison with 1929. Some industries suffered loss of production due to partial displacement by others, such as manufactured ice, which by 1936 had declined to 71.6 per cent of 1929 output. For the most part, however, the drop in production can be attributed to loss in consumer demand, which was especially noticeable in the durable goods and capital goods industries.

Employment.—The series of indices on employment records the average annual employment, as compiled from Bureau of Labor Statistics data. It is consequently not the total actual employment used in the production recorded in the table. It does represent, however, the best available data on average number of workers engaged in these several industries during the calendar year. Of the 67 industries and branches, 20 experienced increases in employment in 1936 as compared with 1929, 3 remained stationary, 43 suffered losses in numbers of workers, and there was one industry for which figures were not available.

Of the 15 large users of labor, each of whom employed more than 100,000 workers, and whose combined labor force was 36 per cent of all manufacturing workers in 1929, 6 had more workers in 1936, while 9 had fewer workers on their payrolls. The latter represented 23 per cent of all who were employed in manufacture in 1929. When workers are distributed by the type of product made, it appears that in the durable goods industries, which are the largest users of labor, only 1 increased employment from 1929 to 1936, while 4 employed fewer workers. Among the ten large labor users making non-durable goods, 6 employed more workers, and 4 fewer workers.

Man-hours.—The series on man-hours gives information concerning the actual quantity of labor used in production. It does not indicate the number of workers employed, but gives the number of hours of employment in particular industries. It is consequently a very significant measure of employment. Of the 66 industrial units represented in the table, data are available for 56. Only 2—side and upholstery leather, and rayon manufacture—actually used more man-hours of employment in 1936 than in 1929. All of the others required less man-hours, some of them showing declines of 50 per cent or more.

Output per wage-earner and per man-hour.—Significant comparisons are made in the table between output per worker and per man-hour of employment. In 35 industries, the output per wage-earner employed increased from 1929 to 1936, in 30 it actually declined. For 2 there were no figures. This is not a measure of technological efficiency or inefficiency, however, for it takes no account of the working time involved in production. Consequently, what is being measured may be either an increase or decrease in the number of hours of employment.

To measure technological change, it is necessary to use the last series in the table, which shows production per man-hour of employment. In 33 of the 56 industrial units represented in the series, man-hour productivity increased from 1929 to 1936, in 9 it remained approximately stationary, while in 4 it actually declined. The increases in man-hour productivity ranged upward to a peak of

241.1 in rayon manufacturing. Some of the gains made in the seven years under review have been startling. In 8 industries they exceeded 50 per cent, while in 22 others they ranged between 25 and 50 per cent.

Comparisons between series.—A helpful comparison can be made between the various series of indices given in the table. For example, the production of agricultural implements declined 27.3 per cent in 1936 as compared with 1929, the number of workers employed dropped off 23.5 per cent, the actual number of man-hours worked declined 38.2 per cent, but the output per employed worker fell off only 4 per cent, and the actual production per man-hour increased 18 per cent. Under these conditions, the industry might have regained its 1929 production level and still used 18 per cent less man-hours of labor than was employed at that time. This does not necessarily require a correspondingly reduced labor force, for the alternative is available of fewer hours of employment per worker.

Beet sugar production is an example of an expanding industry. In 1935 the quantity of beet sugar was 15.2 per cent more than in 1929. But this expanded production was achieved with 9.3 per cent less man hours of labor than was employed in 1929. The reason for such conditions is not far to seek, for the technological efficiency of the labor force had so increased in the six years that the output per man hour in 1935 was 27.0 per cent greater than in 1929.

Ice cream manufacture is an example of an industry whose production was practically the same in 1929 and 1936. Yet in the latter year it required 21.5 per cent fewer workers to make this same quantity of ice cream, and the man hours they worked declined 32.6 per cent. The output per wage earner employed, however, increased 26.1 per cent, and on a man-hour basis this output had grown 46.9 per cent since 1929.

EXHIBIT No. 2438

[Submitted by the Temporary National Economic Committee Staff]

POPULATION AND EMPLOYMENT, 1870-1940

(1) Since the National labor force depends upon total population and its composition, all analyses must begin by seeing what has and what will happen to population. The facts are well known. Total population is growing but the per cent of increase per decade has steadily declined from 26 per cent for that ending in 1880 to 7.7 per cent for that ending in 1940. ("Exhibit 2438-A.")

(2) Young persons seeking a job for the first time (new entrants 20-24 years of age) are now numerically at a peak. No decade has had nor is it probable that any decade in the future will have so great a problem of putting unemployed youth to work as we have. ("Exhibit 2438-B.") On the other hand, the number of workers from 45 to 64 years of age is increasing rapidly. Finding jobs for men

over 40 will in the near future require every scrap of ingenuity that leaders in business and government can summon.

(3) Judging by past trends the percentage of persons who will report themselves gainfully employed will increase from present levels of 40 to 42 per cent of the total population to 50 per cent. The fact that it has risen markedly is due in part to the fact that families have fewer under-age children today than in 1870. ("Exhibit 2438-C.")

(4) Past trends show rapidly declining percentages of total population reporting gainful occupation in agriculture, small declines for manufacturing and mechanical industries and domestic and personal services, and significant increases for those in trade, transportation and communication, professional and public service, and clerical occupations. ("Exhibit 2438-D.")

(5) In terms of the absolute number reporting gainful occupation, agriculture has shown decreases since 1910, the figure dropping from about 12.4 millions at that time to 9.3 millions today. All the other occupational groups have shown increases in each decade. ("Exhibit 2438-E.")

(6) In terms of percentages the story is somewhat different. In agriculture the percentage declined from 47.3 of the grand total reporting gainful occupation in 1870 to 17.5 at the present time. And all the others show increases except those for the mineral industries (which reached a peak in 1920) and the manufacturing and mechanical industries and domestic and personal services (in 1930). The number during the last ten years reporting gainful occupation in these industries has not increased as fast as the total. ("Exhibit 2438-F.")

(7) In 1940 the per cent of absolute increase over 1870 of those reporting gainful employment has been largest in public service (over 2000 per cent), next in clerical service (1670 per cent), then in trade (1170 per cent), then in order, transportation and communication, professional service, mining, forestry and fishing, and domestic and personal service. Those reporting gainful employment in the manufacturing and mining industries have increased 300 per cent while the grand total increased more than 320 per cent. Agriculture has the poorest record. ("Exhibit 2438-G.")

(8) Detailed figures of those in occupational groups show manufacturing most important (27.9 per cent of the total in 1930 reporting gainful occupations there), agriculture next (21.4 per cent), trade (12.9 per cent), domestic service (10.8 per cent). These four accounted for about three-fourths of all employment. In manufacturing a third of all workers said that they belonged in administrative or service jobs, 43 per cent of all transportation and communication workers reported being occupied on the roads and streets (not street railways). Only 10 per cent of those reporting usual occupation in public service were public officials. ("Exhibit 2438-H to N.")

At the outset, it is extremely important to point out that these figures are taken from the Census of Occupations, obtained by census takers in their house-to-house canvass, for a given point of time spaced at ten-year intervals, usually obtained from housewives and not directly from the workers whose occupational status is recorded. They are strictly a record describing the "usual occupation" or "occupation in which customarily employed" of persons whose records are being taken, and under no circumstances must they be confused with a record of actual employment, for they tell nothing about the actual employment status or work record of "gainful workers."

Nor does the census offer data on specific occupations for the whole range of occupational endeavor. For example, the 1930 census divided the total of occupations into ten categories, containing 213 groups, and these groups contained 534 sub-groups, some of which were specific occupations, while others were small families of occupations.

"Exhibit No. 2438" may require some clarification. The upper half shows gainful workers as a proportion of the total population. Much has been made of the presumed fact that because each census has shown a larger proportion of the total population listed as gainful workers, the economy was healthy, always finding employment for a larger proportion of its people. But the Census of Occupations, as before stated, is a measure, at a given time, of the number of people customarily on the labor market, and not a measure of employment. While the percentage of "gainfully employed" increased in successive decades from 1870 to 1910, represents in large part a transition from a barter to a pecuniary economy. The unpaid housewife or spinster, for example, has become a woman in industry. She followed baking, laundering, etc., out of the home, but got money for it. Moreover, the number of children per family has decreased more than a third since 1870. The drop in gainfully employed from 41.5 per cent in 1910 to 39.8 per cent in 1930 may reflect changes in social policy with respect to child labor, and also increased

prosperity. If so, it seems likely that the percentage in 1940 may, if anything, be the same or higher. It is estimated that by 1960 the gainfully employed will constitute 50% of the total population.

In the lower half of Exhibit 2438-C, which shows such a marked change in occupational emphasis during the past 70 years, the ten familiar occupational categories are regrouped into three: agricultural, manufacturing and mechanical, forestry and fishing, and mining occupations are called "producing industries;" trade and service occupations are grouped together; and transportation and communication make up the third functional class. The producing industries, which included 77 per cent of all gainful workers in 1870, comprised only 46.5 per cent in 1940. Trade and service occupations, on the other hand, moved from 20 per cent of all gainful workers in 1870 to 44.3 per cent in 1940. Transportation and communication included 3.2 per cent of the gainful workers in 1870 and 9.2 per cent in 1940.

Accurate interpretation of the remaining charts is easy if the essential point is remembered that "gainfully occupied" does not mean "actually employed."

The wide dissemination of that fallacy is strikingly shown in an article entitled "Science, The Soul of Prosperity," by Dr. Karl T. Compton, President of the Massachusetts Institute of Technology, published in *Think*, Volume VI, No. 3, March, 1940, p. 10 et. seq. On page 34 he states:

"There has been so much misconception in regard to the effects of technological progress upon employment and standards of living that I am going to run the risk of boring you with a few facts. * * *

"Between 1900 and 1930, the greatest thirty-year period of technological development in history, employment in the U. S. increased by more than 20,000,000 jobs.

"Even during the recent depression a larger proportion of the population were wage earners than in periods which were considered prosperous seventy-five or one hundred years ago." (Emphasis is the author's.)

Such so-called facts are not boring. They are amazing. Presumably Dr. Compton bases his contention on reports of the Census of Occupations, which enumerated 29,073,233 persons reporting a usual gainful occupation in 1900 and 48,829,920 such in 1930, a difference rated at "more than 20,000,000 jobs." But even in the very year 1930 for which he uses occupational data, an employment census was taken (in April, so it happened; the average figure for the year must have been much higher), showing at least 3,138,000 actually unemployed of those Dr. Compton counts as in "employment" or "jobs." This ignores the part-time jobs and the economic and social changes which shifted many activities from reward in kind to payment in money, from an unpaid household status to a pecuniary basis.

The dross in the second and more emphatically stated of his "facts" is in part the same. The term "wage earners" does not seem to be meant in the careful, scholarly sense in which the Brookings Institution has used it, for example, in Exhibit 2437, where the percentage since 1880 is shown to have been about 52 or 54 per cent, falling somewhat after 1910. If Dr. Compton means to say that the percentage *actually employed* was larger in 1932 than, say, in 1830, he must possess information not elsewhere available, because no Census of Occupations was taken in 1830.

If he is making a comparison with 1870, and is referring to the percentage of the total population reporting customary occupations then, he is probably incorrect. The figure in 1870 was about 32.5 per cent. In 1932 the National Industrial Conference Board estimated total employment at 37.5 millions. Midyear estimates of population made by the Brookings Institution in its volume entitled *The Recovery Problem in the United States* are 125.0 millions for 1932 and 125.8 millions for 1933. The resulting percentage is 30 per cent.

The statements which Dr. Compton makes have appeared in almost identical form in many places. Thus, for example, the Machinery and Allied Products Institute, in their pamphlet entitled *Machinery and the American Standard of Living—An Illustrated Factual Story of the Contributions of Technology to American Civilization*, (Chicago, 1939) state on page 20:

"In 1870 about 32 out of every 100 persons in the United States were gainfully employed, according to the United States Census. In 1930, according to the last census, about 40 out of every 100 were gainfully employed. Back in 1830 only 27 out of every 100 persons in the United States were gainfully employed. Thus, there was an increase in 100 years of almost 50 per cent in the proportion of the population gainfully employed. Even in the years of most severe depression in the 1930's the percentage was higher than in periods considered prosperous prior to 1900."

Similarly the National Association of Manufacturers in a pamphlet entitled *Men and Machines*, one of the well known *You and Industry Series* which are given nation-wide free distribution to schools, women's clubs, study groups, and individual citizens, states:

"Even admitting the benefits of the machine to the consumer, these are serious charges (that the machine is responsible for unemployment) requiring factual evidence to bring out the truth.

"What are the facts?

"* * * (The table) described how between 1870 and 1930, the last census year, while the population increased 218 per cent, those engaged in gainful occupations increased 290 per cent, and that is during the period of the most intensive development of the machine."

Quotations from other sources which have similarly fallen a victim to this fallacy could readily be multiplied.

CAPITAL-SAVINGS INNOVATIONS

The number of capital-savings innovations recently perfected is legion. A few examples will suffice, taken for the most part from a study of David Weintraub entitled "Effects of Current and Prospective Technological Developments upon Capital Formation." *American Economic Review*, Vol. XIX, No. 1, March 1939. The superior performance of modern steam hammers widely used for drop forging is such, that although the price of a current model is about the same as that of a 1905 model, a decline of more than 55 per cent has been brought about in the investment per unit of work accomplished.

In numerous ways large capacity equipment tends to operate at less cost per unit of capacity than small. A steam electric generating station operates at a cost from \$135 to \$150 per kilowatt for capacities of 2,000 kilowatts and only \$92 to \$115 for 200,000 kilowatts. Likewise in Diesel plants the investment per unit of capacity declines from \$230 for 100 kilowatts of capacity of \$106 for one of 10,000 kilowatts. Larger machinery usually requires smaller amounts of fuel and also of labor per unit of capacity or of output. Installation costs are likewise lower as is the amount of floor space required per unit of capacity.

Moreover, industrial measuring, recording and controlling devices bring about uniformity of operation and help to minimize the wear on machinery. In one test case, boilers under hand control had to be rebricked every three months while with instrument control no rebricking was required even once a year.

Furthermore, the "topping" technique in which exhaust steam from high pressure, high temperature turbines is utilized by being discharged into the steam headers of lower-pressure units, tends to increase the capacity of existing stations from 40 to 90 per cent without an increase in fuel requirements and without corresponding additions to plant and equipment, a fact sometimes ignored by those who state the capital investment needs of utilities. In the period from January 1936 to May 1937 topping units represented more than 75 per cent of the total turbine capacity installed in central stations using pressures of 1000 pounds or more.

Through chromium plating the life of various tools and parts has been extended from 3 to 20 times. By the use of tungsten carbide, carboloy tools have been formed which operate in some cases 300 to 400 times as efficiently as the old steel tools. On a brass-plug job the number of finished pieces produced by old tools was 200, through the substitution of carboloy tools this was increased to 15,000. Welding has been substituted for casting, roller bearings for old type friction bearings which has meant increased speed of operation, greater durability of machinery and reduction in total power requirements in recently installed machinery. Similarly, improvements in paints, varnishes, and lacquers, as well as erosion-resistant steel alloys and plated steels have meant huge savings on inventories and storage space for the automobile manufacturer in addition to lowering the drying time from 26 days to a few hours.

The improvement in the mineral industries due to the use of recent chemical concentration and flotation processes has been one of the most remarkable achievements of the last 10 years. Also noteworthy have been the mechanization of conveying operations and of the handling of bulk materials.

The story of the savings of fuel is also familiar. By the use of devices for retrieving the heat formerly lost in stack gases or hot products and using it for pre-heating raw materials and air for combustion or for generating steam; by reductions in heat and power requirements through adoption of speedier and more continuous methods of manufacture; by the prevention of heat losses through insulation, seals against cold-air leakage; by improved techniques for more efficient transfer of heat and power; and, in particular, by more exact controls through recording instruments, great fuel economies have been achieved on the railroads and by public utility stations and elsewhere.

Similarly in the rayon industry in the "thirties" costs of production have been cut about 50 per cent, most of the decrease in costs being due to refinements of detail in processing and spinning machinery, improvements in precipitating bath composition and in washing procedure, and the use of more uniform and purer materials. Even in the telephone industry, which has always been regarded as the classic example of an industry subject to diminishing returns where fixed capital requirements grew faster than increases in the number of telephones installed, recent and current technical changes such as the introduction of carrier

current systems or of the coaxial cable are increasing the capacity of the telephone plant with less than a proportional increase in fixed capital investment.

In the report of President Hoover's Committee on Recent Economic Changes in the United States, Volume 1, a table is given, excerpts from which (Exhibit No. 2438-A) show in dollars and cents the substantial savings and increases in output which were made possible by the utilization of new types of apparatus, standard conveyers, hoists, tractors, locomotive cranes, gravity chutes and the like. Processes have been made continuous with the result that savings are secured in floor space, in inventories, in storage room, in machinery and auxiliary equipment, and in costs of maintenance and repairs while wastes have been eliminated, spoilage reduced, and the whole process considerably speeded up.

Industrial processes

Process	Process supplanted	Savings	Company
CHEMICAL			
Refining edible oils.....	Old processing tanks.....	1/4 cost of old process.....	American Linseed Co.
Eliminating corrosion in water circulating systems by use of sodium chromate.		\$25,000 per yr. in repair bills \$75,000 due to elimination of lost time in plant.	Midwest Refining Co.
Recovering borax.....		Present production costs are less than 10 percent of those of 1919.	American Potash & Chemical Corporation.
ELECTRICAL			
Filament material for radio tubes.	Using base metals in place of platinum for oxide coated filaments.	Annual saving of about \$3,000,000.	Westinghouse Electric & Manufacturing Co.
Automatic arc welding.....	Hand welding.....	Annual saving about \$60,000.	Cadillac Motor Car Co.
MECHANICAL			
Pressing linseed.....	Eliminates press cloths and about two-thirds labor.	Four cents per bushel of linseed crushed.	American Linseed Co.
Dry quenching.....	Cooling of hot substances by liquids.	In a water gas plant, fuel saving of 2.3 pounds per 1,000 cubic feet gas made.	Dry Quenching Equipment Corporation.
Utilization of powdered coal.	Stoker firing.....	Operating efficiency 6 to 8 percent higher than for stoker firing.	Combustion Engineering Corporation.
METALLURGICAL			
Leaching process.....		Recovery of approximately 20,000,000 pounds copper per year, previously wasted.	Calumet & Hecla Consolidated Copper Co.
Centrifugal cast pipe manufacture.	Sand-cast process.....	Reduction of equipment and labor. Great savings in time.	United States Cast Iron Pipe & Foundry Co.
Electric-thermic smelting.		Reduced selling price of ferro-vanadium about 25 percent.	Vanadium Corporation of America.
PETROLEUM REFINING			
Cracking of heavy petroleum hydro-carbons.	Old pressure distillation type of apparatus.	Reduction of fuel consumption about 80 percent.	Kansas City Testing Laboratory.
METAL WORKING			
Drilling long oil holes.....	Replaces method using two spindle horizontal machines.	\$6,000 per year.....	Cadillac Motor Car Co.
Utilizing diamond tools...	Old method of boring and reaming holes with steel tools.	Annual saving about \$15,000.	Cadillac Motor Car Co.
Roughing outforging billets.	Old swaging or fullering method.	Annual saving about \$20,000.	Cadillac Motor Car Co.
Arc welding.....	Riveting.....	Economies effected in time and labor.	Newport News Shipbuilding & Dry Dock Co.

Industrial processes—Continued

Process	Process supplanted	Savings	Company
RUBBER			
Automatic tube molding.....	-----	Manufacturing costs reduced about 40 percent and quality improved.	Fisk Rubber Co.
Development of age resisters.....	-----	Estimated savings to consumers about \$50,000,000 per annum.	B. F. Goodrich Co.
MISCELLANEOUS PROCESSES			
Elimination of crazing.....	Replaces process of dry pottery.	Fuel savings from 75 to 85 percent.	Homer Laughlin China Co.

Fifty typical installations of material-handling equipment

Material or product handled	Equipment used	Plant	Savings and improvements
AUTOMOBILES AND ACCESSORIES			
Cylinder blocks.....	Standard conveyors.....	Nash Motor Co.....	\$8,600 per year.
Annealing pots.....	Tier-lift trucks.....	New Departure Mfg. Co.	\$10,800 per year.
BUILDING MATERIAL			
Materials.....	Overhead carrying system.	Architectural Tile Co....	\$5,000 per year.
Cement materials.....	2 hoists.....	Crex Patent Column Co.	\$6,000 per year.
Sand and gravel.....	Portable conveyor and loader.	Crume Brick Co.....	\$3,900 per year.
Lumber on trailers and switching cars.	Trutractor.....	M. B. Farrin Lumber Co.	\$4,650 per year, congestion eliminated; 15 horses eliminated; 70 percent return on investment.
Building material.....	Locomotive cranes.....	Dwight P. Robinson Co.	\$18,000 in six weeks.
Lumber.....	Locomotive cranes.....	St. Helena Dock & Terminal Co.	\$41,000 per year.
Crushed stone.....	Belt conveyor.....	Leatham D. Smith Stone Co.	Double capacity.
FOOD			
Sugar.....	Automatic packing and handling equipment.	American Sugar Refining Co.	One-half of labor.
Coal and ashes.....	Bucket conveyor.....	George Ehret Brewery Co.	Equipment handles 20,000 tons of coal per year at 9 cents per ton including maintenance and repair charges.
Coal.....	Conveyor.....	Freeman Dairy Co.....	\$0.98 per ton; \$2,500 per year.
Sugar packed in cartons.....	Conveyors.....	National Sugar Refining Co.	\$8,800 per year.
Candy in boxes and cartons.	Gravity conveyors and spiral chutes.	Samest Chocolate Co....	\$3,370 per year.
Materials.....	Overhead trackway connecting all departments.	Swift & Co.....	\$125,000 per year; \$0.60 per ton material handled.
FOUNDRY			
Cupola charges.....	Hoist.....	Davis & Thomas Co....	\$5,850.
Castings.....	Belt conveyors.....	Kelsey Wheel Co.....	\$10,000 per year.
Materials.....	3 trutractors.....	Southside Malleable Castings Co.	\$22,500 per year.
Castings.....	Trutractors.....	Standard Sanitary Mfg. Co.	Annual savings 17 times cost of equipment.

Fifty typical installations of material-handling equipment—Continued

Material or product handled	Equipment used	Plant	Savings and improvements
IRON AND STEEL			
Iron and steel.....	2 tractors.....	American Radiator Co..	\$22,000 per year; \$1,845 per ton
Steel, machinery, forgings..	2 locomotive cranes.....	E. W. Bliss Co.....	Equipment pays for itself each year.
Iron and steel.....	15-ton locomotive crane.	Delaware River Steel Co.	\$10,800 per year.
Rails.....	Locomotive crane.....	McKenna Process Co..	Doubles production.
Steel (on buggies).....	Tractor.....	Riter-Conley Mfg. Co..	\$2,960 per year; saves \$8,000 in increased production; labor turnover reduced; pays for itself in about 64 days.
Iron and steel scrap.....	Locomotive crane.....	Sonken-Galamba Iron and Metal Co.	\$30,000 to \$40,000 per year big saving in time.
LEATHER			
Flashings.....	Tractor.....	Joseph Eisendrath Co..	\$3,400 per year.
Patent leather in frames..	Overhead carrying system.	Gress-Pfleger Tanning Co.	\$5,000 per year.
MACHINERY			
Shipping cases.....	Gravity chute.....	General Electric Bloomfield plant.	\$6,000 per year; rapid loading of cars.
Castings and foundry supplies.	4 tractors and trailers.	Holt Mfg. Co.....	\$13,300 per year.
Materials.....	8 cranes.....	Reliance Electric & Engineering Co.	\$9,350 per year.
METAL WORKING			
Materials.....	Complete conveyor system.	Belden Mfg. Co.....	Yearly profit \$12,450 on investment of \$19,611.
Materials.....	2 tractors.....	Bullard Machine & Tool Co.	\$10,500 per year.
Assembling stoves.....	Conveyor.....	Detroit Vapor Stove Co.	Increases production; saves 50 percent of space.
Materials.....	Roller and belt conveyor	Hobart Bros. Co.....	Cut production cost 25 percent.
Dies.....	Tier-lift truck.....	Ireland & Matthews Drop Forging Co.	\$32,000 per year.
Materials and product....	3 elevating conveyors....	Tin Decorating Co.....	\$47,400 per year.
Materials.....	Overhead carrying system.	United Metal Co.....	\$7,500 per year.
Coal, coke, ores, and slag..	Locomotive crane.....	United States Metals Refining Co.	Increased production 100 percent.
Materials.....	Stationary roller conveyors and containers.	Walworth Co.....	\$80,000 per year.
PAPER			
Paper.....	Skids for loading box cars.	Champion Coated Paper Co.	Reduction in labor 63 percent.
Paper.....	Electric hoist.....	Paper Manufacturers Co., Inc.	Increased production on one process 66 percent.
Paper in rolls to cutting machines.	5 hoists.....	Paterson Parchment Paper Co.	\$4,100 per year.
Paper and paper stock....	Nailed wooden skids for shipping.	West Virginia Paper and Pulp Co.	Reduction in shipping material cost 77 percent; reduction in labor in handling shipments, 80 percent.
TEXTILES			
Materials.....	Complete conveyor system for mill.	Jackson Mills.....	\$16,250 per year; successful material control and improvement in machine operations.
Raw cotton.....	Pneumatic conveyor.....	Milstead Mfg. Co.....	\$1,500 per year.
MISCELLANEOUS			
Lumber and materials....	Miscellaneous handling equipment.	American Seating Co..	Reduced handling cost per man-hour from 17 to 6 cents; annual saving, \$95,000; additional saving over handling improvement about \$25,000 per year.

Fifty typical installations of material-handling equipment—Continued

Material or product handled	Equipment used	Plant	Savings and Improvements
TEXTILES—continued			
Materials.....	Conveyor system for entire plant.	B. T. Babbitt Co.....	Unloading costs \$0.02 per box for metal cans; \$0.02 per drum for caustic soda; \$0.04 per drum for lime; \$0.50 per thousand for fiber boxes; \$1.50 per thousand for wooden boxes; shipping cost \$0.0075 per package.
Flaxseed from ship to storage to mill.	Conveyor and elevating system.	Bisbee Linseed Co.....	\$15,000 per year.
Clay.....	Trutractor.....	Champion Porcelain Co.	\$8,400 per year.
Materials and products.....	Complete system of conveyors, elevators, lift trucks, spiral chutes, and gravity devices.	E. R. Squibb Co.....	Elimination of unnecessary travel of material in process and finished product.

CLINTON DAVIDSON, JR.
Economist

WILLIAM H. COMBS & Co.

MEMBERS OF NEW YORK STOCK EXCHANGE

61 Broadway New York,

THE MYTH OF A PROFITLESS PROSPERITY

By Clinton Davidson, Jr.

It is commonly believed that under the New Deal profits are subnormal even when production rises to a normal level, and years of good business activity like 1936, 1937, 1939 and so far in 1940 are called periods of "profitless prosperity".

As a consequence of this belief many investors are deterred from making investments in stocks when the business outlook is good, many economists are frequently too pessimistic in their business forecasts, and serious mistakes are made from attaching too much importance to political developments in appraising the *short term* outlook. For example, many people have recently ignored the unfavorable elements in the business picture today and have been buying stocks solely on the expectation that Roosevelt will not be reelected, that profit margins will improve under a Republican administration, and that business will boom as a result of large investment in plant and equipment induced by the higher profit margins.

Since so much emphasis is being placed by many economists and investment counsellors on the subject of profit margins in the manufacturing industry as affected by politics in making their forecasts for 1941, this subject should be examined thoroughly.

Profits are believed to be subnormal in relation to business activity because wage rates per hour have been rising while finished goods prices have declined. Note in line (4) on the Exhibit that wage rates per hour rose from 56¢ in 1925 to 72¢ per hour in 1939, while the index of prices shown in line (5) fell from 100 to 80. This is cited as evidence that labor is getting more and the entrepreneur less out of the total value of production. Investment in plant and equipment is believed to be stagnant because new capital security issues have diminished. For the reasons to be explained in a moment, I believe both of these commonly held beliefs are incorrect.

In the first place, wage rates per hour are not indicative of labor costs because they are modified by changes in labor productivity. It is the labor cost per unit of output that is important. As shown in line (4) on the Exhibit, wage rates rose from 52.4¢ an hour in 1921 to 59¢ in 1929, but the worker was paid 12% more in 1929 because he could produce with an hour's labor about 30% more than he could in 1921. The manufacturer consequently had lower labor costs in 1929 in spite

of higher wage rates per hour. If wage rates are considered as identical with labor costs, such costs, adjusted for price changes, have been rising steadily during the last 150 years, as wage rates have continuously risen in line with increasing labor productivity.

While some economists are aware that labor costs per unit of output have declined during the last ten years because of increased efficiency, they argue that finished goods prices have declined even more, and accordingly labor costs per dollar of output have risen. In fact, the national industrial conference board publishes an index of labor costs per dollar of output, and a stock exchange firm recently used this index in a "market letter" to demonstrate that high labor costs have wiped out the manufacturers profit. The fallacy of this argument is that it overlooks the simultaneous decline in raw material costs.

If this firm had made a similar analysis in 1929, it would have noticed that finished goods prices were 27.5% below 1919 while labor costs per unit of output were only 20% lower. Following this reasoning, it would have stated that labor costs were eating into profits, and that because of subnormal profits new investment in plant and equipment must be very small. Of course, profits in 1929 were high because raw material costs had declined more than finished goods prices.

How can we find a true measure of labor costs that takes into consideration changes in labor productivity and the spread between finished goods prices and raw material costs? It is necessary to consider these factors, if we wish to determine whether labor costs are squeezing profits or not. For profits are affected not by wage rates per hour alone but also by the amount of goods that can be turned out with one hour's labor and by the spread between finished goods prices and raw material costs.

To find a measure of labor costs that includes these important factors, the first step is to subtract raw material costs from the value of manufactured products, which gives us a gross profit called the "value added by manufacture". This is done in the Biennial Census of Manufactures, and the result is shown in line (1) of the Exhibit. The next step is to take all wages paid in manufacturing, which also appears in the Biennial Census of Manufactures and is shown in line (2). In calculating his expected profits the manufacturer is interested in the proportion of wages paid to the value added by manufacture or gross profit. This proportion is shown in line (3) in the Exhibit as a percentage. When this percentage rises, labor increases its share of gross income and profits are squeezed. When it falls, profits comprise a larger share of gross revenues.

Before commenting on these figures, I must point out that the "value added by manufacture" for 1939 has not yet been reported and accordingly had to be extrapolated with the aid of those production statistics available and certain wholesale commodity price indexes. Wages were extrapolated by the Bureau of Labor Statistics. The figures for 1940 are extrapolated on the basis of the last few months when industrial production was about the same as the 1929 average.

Note in line (3) on the Exhibit that the percent of labor costs to "value added" declined about 8 points from 1921 to 1929, in spite of the fact that wage rates per hour, shown in line (4), rose 12%, and finished goods prices, shown in line (5), declined 9%. This was due to the increasing productivity of labor. In 1935 under Roosevelt the percent of wages to "value added" was slightly lower than in 1925 under Coolidge, although wage rates per hour had risen 7% and finished goods prices had fallen 18% in the ten year period. Of course, this isn't Mr. Roosevelt's doing; the credit is due to the manufacturer who increased his efficiency enough to permit this rise in real wage rates.

In 1937, despite the activities of the C. I. O., the proportion of wages to value added was 39.3%, roughly the same as in 1925. I believe the estimate of 39.2% for 1939 errs on the high side, and we will be able to check this a year from now when the Census of Manufactures for 1939 is available. During the last few months labor costs have been lower than for any year in the 1920's except 1929. This is due to the fact that labor efficiency increases as production rises nearer to capacity.

Labor costs are not the only factor to be considered, however, in calculating profit margins. Changes in "overhead" production costs such as taxes, interest and depreciation must also be considered. We all know that corporation taxes have risen under the New Deal, but higher taxes have been offset by lower interest rates and lower depreciation charges per unit of output when production is at the current high level. While we all agree that overhead costs are relatively inflexible, and therefore on a per unit of output basis vary inversely with the level of production, the statement that depreciation charges today with the same volume of output do not need to be so large as in 1929 does require explanation.

But first let us make a rough check on the statement that these offsetting cost declines have made manufacturing as profitable today under the New Deal as in years of comparable business activity in the 1920's by referring to manufacturing corporations income tax returns. The Statistics of Income for all *manufacturing* corporations are analysed in lines (7), (8), (9) and (10) in the Exhibit. These figures have been computed by the National City Bank and appeared in their monthly bulletin of November 1939. Line (7) shows that gross revenues in 1937 were slightly below 1927. If allowance were made for price changes, they would be about \$4 Billion higher. The two years are particularly comparable because production and prices were declining throughout the year in both cases, and profits were somewhat reduced by inventory losses. As shown in line (9), the per cent of net profits after taxes to gross revenues was about 4% in both years.

The chief difference between the two years is that less capital was needed for the same volume of sales in 1937 than in 1929 so that net worth was about \$8 Billion lower. As a result of this greater turnover of capital, the per cent earned on net worth, shown in line (10), was 8% in 1937 against 6.6% in 1927. This is very important because the manufacturer looks at the per cent earned on net worth in determining whether a new investment in capital equipment is likely to be profitable enough to warrant the trouble he takes.

The reason why net worth is lower today than 10 years ago also explains why depreciation charges do not need to be as high, and why new capital security issues have apparently been subnormal. The reason is found in the increasing productivity of modern machinery.

While it is impossible to make an overall estimate of capital equipment productivity like our estimate of labor productivity, we can draw conclusions from individual industries in which such an analysis can be made.

The cotton textile industry, one of the largest and most important of our manufacturing industries, affords an excellent opportunity for capital equipment productivity analysis. Capital equipment in this industry is measured by spindles and looms in place. The number of spindles in place in 1937 was 19% less than in 1929, and average active spindles during the year were 21% less. But with less equipment cloth production was 12% higher in 1937 than in 1929. Each active spindle produced 392 square yards of cloth in 1937 against only 276 square yards per spindle in 1929. This was not due to more work shifts, for spindle hours run in 1937 were 4.4% below 1929. Cloth production per spindle hour run in 1937 was 17% higher than in 1929. This is a true measure of capital equipment productivity. Looms in place in 1937 were 28% less than in 1929, and average active looms were 26% less. In 1939 the number of spindles in place and average active spindles declined further to a new low but cloth production was 10% above 1929 and cloth produced per active spindle was 410 square yards, which was 49% above 1929.

It is interesting to note, incidentally, that new spindles installed in 1939 were 349,416, an increase of 9% over 1929, which indicates plenty of incentive to invest. Here then is an industry which has discarded more capital equipment each year than has been replaced with new equipment but can still produce more now than in 1929 when 27% more equipment was being used. Thus, the total capital invested in the industry has declined as the result of retirements from depreciation without any decline in actual productive capacity.

Capital equipment productivity in the cotton textile industry

	1929	1933	1937	1939

* Estimated on basis of spindle hours run.

The American Woolen Company states in its report for 1939 that it has only about half as much plant and equipment today as in 1924 but nevertheless has the actual capacity to turn out the same amount of goods.

The electric light & power industry has also increased its actual capacity more than its investment in fixed capital. While the gross book value of fixed capital increased only 16% from 1929 to 1939, generating capacity increased 27% and energy output increased 36%.

The capital investment of the steel industry declined 18% from 1929 to 1939, but ingot capacity increased 17%. The American Iron & Steel Institute in its publication "Steel Facts" for March 1940 presents a study of capital equipment productivity in the steel industry, from which I have taken the following quotations:

"The design and operation of open hearth furnaces, which produce about nine-tenths of the total steel ingot output, have been greatly improved in recent years. These improvements account for most of the increase in steel capacity which has occurred as a result of technological progress over the past ten years.

"Effect of these improvements upon output is shown by the production records of four representative open hearth furnaces in two periods of peak operation—1929 and 1939. An average increase of 31 per cent in output is shown by records of the four furnaces.

"The average daily output of a typical 170-ton furnace increased from 302 tons per day in 1929 to 395 tons in 1939, a rise of 31 per cent. A smaller furnace, rated at 110 tons per heat, produced 186 tons per day in the peak month of 1929 and 265 tons, or 43 per cent more, in the best month of last year. Similarly the average daily output of an 85-ton furnace rose 35 per cent, from 133 tons to 179 tons, in the past decade.

"Among the principal reasons for the increase in productivity of open hearth furnaces are the increased use of steel scrap as a raw material, the redesign of furnaces to permit the charging of greater quantities of raw materials, and the introduction of improved auxiliary equipment."

Two significant observations can be drawn from this capital equipment productivity analysis. (1) Depreciation charges per unit of production are substantially lower when capital equipment is fully utilized today, than was the case in 1925-1929. For example, the annual depreciation at 10% on \$1 Million of machinery capable of producing \$1 Million of goods in 1929 was \$100,000 or 10¢ per dollar of production. If today \$1 Million of machinery can turn out \$1,200,000 of goods, or 20% more, the annual depreciation is still \$100,000, but this is at the rate of only 8.35¢ per dollar of production, a saving of 1.65% per unit of output. (2) Actual capacity can be increased today by replacing fully depreciated equipment with modern equipment without adding to the gross book value of the capital account, and no new securities need to be issued to finance this expansion of capacity. For example, using the illustration above, when the \$1 Million of machinery bought in 1929 is fully depreciated on the books in 1939, it is discarded and \$1 Million of new machinery is bought with the funds represented by the depreciation reserve. Since the new machinery can produce 20% more than the old, productive capacity is increased 20% without the need of raising any cash by the sale of securities.

This explains why capital expenditures by manufacturing corporations in the last 10 years have not entirely offset depreciation charges, while at the same time productive capacity has actually increased. New security issues, consequently, are largely sold to raise funds for new industries such as airplane manufacturing and transport companies, and chemical companies. Another explanation for the apparently subnormal volume of new capital issues referred to by economists is that they include issues for real estate other than factories, for financial institutions and for holding companies that intend to purchase operating companies. New capital issues for manufacturing corporations alone have averaged a little less than \$1 Billion per year in recent years against around \$1.5 Billion in the 1920's. At no time have new capital security issues represented a significant proportion of actual expenditures for capital equipment.

The proof of this statement is found in the statistics on expenditures for plant and equipment calculated by George Terborgh of the Federal Reserve Board, shown in line (11) in the Exhibit. In 1937 these expenditures in the mining and manufacturing industries were larger than in 1919, 1921, 1923, 1925, and 1927. If allowance is made for price changes, they were practically as large as in 1929.

In 1939 such capital expenditures were slightly lower than in 1925 and 1927

in current prices, but when allowance is made for price changes were \$3 Billion in 1925 prices or about 10% above 1925 and 1927 in physical volume. Since new capital security issues were substantially lower in 1937 and 1939 than in the 1920's while capital expenditures were just as large, there is obviously no correlation between the two.

In conclusion, wage rates have risen while finished goods prices have declined, *not* because of the activities of labor unions and the labor legislation of the New Deal, but rather because the use of modern machinery has increased labor productivity and capital equipment productivity enough to permit manufacturers to grant these wage increases without sacrificing any profits. Roosevelt can not claim the credit for wage rates today being 23% above 1929. The credit belongs to the manufacturers who have increased the productivity of labor about 30% during the last 10 years, which is only slightly less than the increase from 1919 to 1929.

This study also indicates that profits are good in the manufacturing industry whenever consumer demand for its products is normal, and that investment in plant and equipment in this industry is not lagging. Thus, if the *only* effect of throwing out the New Deal in the coming election is to change its labor and tax laws, our problems will not be solved and business is not likely to be stimulated by any large increase in capital outlays on the part of the manufacturing industry.

The problems to be solved lie rather in the field of housing, commercial building, durable consumer goods, foreign trade, and agricultural adjustment. In appraising the outlook for business activity and corporate profits in the future, it is accordingly preferable to consider the effects of political and other developments on these fields of economic activity which are currently subnormal and in need of important stimulation. Even in the boom years 1929 and 1937 investments in plant and equipment in the manufacturing and mining industry absorbed only one-fifth of the nation's gross savings. Gross investments in other fields of economic activity normally absorb four-fifths of the nation's savings, and are four times as important as investments in manufacturing and mining in stimulating the nation's purchasing power. In view of the fact that the manufacturing industry has solved its problems and has done more than its share toward bringing about economic recovery, it seems to me that we will make better progress if politicians and economists devote more of their energy toward solving the problems in these larger fields in which investment has been subnormal instead of spending most of their time in considering political policies in relation to the manufacturer.

[Submitted by the Temporary National Economic Committee Study Staff]

EFFECTS OF THE RADIO TELEGRAPH AND TELEPHONE AND OF RADIO BROADCASTING

I. ON UNIFORMITY AND DIFFUSION

Regional differences in cultures become less pronounced.
The penetration of the musical and artistic city culture into villages and country.
Isolated regions are brought in contact with world events.
Illiterates find a new world opened to them.
Standardization of diction and discouragement of dialects.

II. ON RECREATION AND ENTERTAINMENT

The manufacture of better phonograph music records encouraged.
Establishment of the melodramatic playlet with few characters and contrasted voices.
Greater appreciation of the international nature of music.
Entertainment for invalids, blind, partly deaf, frontiersmen, etc.
Interest in sports increased, it is generally admitted.
Entertainment on trains, ships and automobiles.

III. ON TRANSPORTATION

Radio beams, enabling aviators to remain on course.
Aid furnished to ships in distress at sea.
Brokerage offices on ships made possible.
Receipt of communications en route by air passengers.
Communication between airplanes and ships.
Ships directed for better handling of cargoes.

IV. ON EDUCATION

Broadcasting has aided adult education by talks on political, economic, health, and other questions.

V. ON THE DISSEMINATION OF INFORMATION

Wider education of farmers on agricultural methods, parasites.
Prevention of loss in crops by broadcasting weather reports.
Market reports of produce permitting better sales.
Important telephone messages between continents.
Small newspapers, an experiment yet, by facsimile transmission.
Transmission of photographic likenesses, letters, etc., especially overseas where wire is not yet applicable.
Quicker detection of crime and criminals, through police automobile patrols equipped with radio.

VI. ON RELIGION

The urban type of sermon disseminated to rural regions.
Services possible where minister cannot be supported.
Invalids and others unable to attend church enabled to hear religious service.

VII. ON INDUSTRY AND BUSINESS

Better phonograph recording and reproducing now used.
Lowering of cable rates followed radio telegraph development.
The business of the lyceum bureaus, etc., suffered greatly.
Equipment cost of hotel and restaurant increased.
A new form of advertising has been created.
Led to creation of new magazines.
An increase in the consumption of electricity.
Provision of employment for 200,000 persons.
Aid to power and traction companies in discovering leaks, through the assistance of radio listeners.

VIII. ON OCCUPATIONS

A new employment for singers, vaudeville artists, etc.
 New occupations: announcer, engineer, advertising salesman.
 Dance orchestras perhaps not increased but given prominence.

IX. ON GOVERNMENT AND POLITICS

In government, a new regulatory function necessitated.
 Legal questions raised beginning with the right to the air.
 New specialisation in law; four air law journals existing.
 Executive pressure on legislatures, through radio appeals.
 Rumors and propaganda on nationalism have been spread.
 Constituencies are kept in touch with nominating conventions.
 Political campaigners reach larger audiences.
 High government officers who broadcast are said to appear to public less distant and more familiar.

X. ON OTHER INVENTIONS

The vacuum tube, a radio invention, is used in many fields, as for leveling elevators, automatic train controls, converting electric currents, applying the photoelectric cell, as hereinafter noted. A new science is being developed on the vacuum tube.
 Television was stimulated by the radio.
 Developments in use of the phonograph stimulated by radio.
 Amplifiers for radio and talking pictures improved.
 Geophysical prospecting aided by the radio.

XI. MISCELLANEOUS

Morning exercises encouraged a bit.
 Irritation against possible excesses of advertising.
 Development of fads of numerology and astrology encouraged.
 Wider celebration of anniversaries aids nationalism.
 Used in submarine detection.
 Home duties and isolation more pleasant.
 Creative outlet for youth in building sets.

More Detailed Effects.—For instance, the item of the foregoing list, "Interest in sports increased, it is generally admitted", when analyzed in further detail shows fifteen further social effects, which are as follows: The Broadcasting of boxing matches and football games tends (1) to emphasize the big matches to the neglect of the smaller and local ones, (2) increasing even more the reputation of the star athletes. In the case of football (3) the big coaches are glorified and (4) their salaries become augmented. (5) The attendance at colleges specializing in football whose football games are broadcast is increased. (6) Football practice in the springtime is thus encouraged and (7) the recruiting of prospective star players for college enrollment is fostered. (8) The smaller colleges or the ones with higher scholastic requirements tend to be differentiated as a class by contrast. (9) Boxing matches with big gates have accentuated trends in boxing promotion, notably the competition for large sums of money to the neglect of smaller matches. (10) Broadcasting of sports has led to a greater advertising of the climate of Florida and California, and (11) no doubt has aided a little the promotion of these two regions. (12) Broadcasting of sports has led to the developing of a special skill in announcing the movements of athletes not at times easy to see, a skill rather highly appreciated. (13) Athletic and social clubs with loud speakers have become popularized somewhat on the afternoons and evenings of the matches. (14) The broadcasting of baseball games is said to have bolstered the attendance, particularly by recapturing the interest of former attendants. (15) Another effect it is said has been the reduction in some cases of the number of sporting extras of newspapers.

1840-1849	49	56	1913	100	100
1850-1859	58	52			

Data for England: *Economic Journal*, September 1923; *Journal of Statistical Society*, March, 1909; *Review of Economic Statistics*, October 1923; Suppl. for U. S. A.: *American Economic Review*, March 1925.

The article of Rufus S. Tucker, "Real wages of artisans in London 1729-1935" (*Journal of the American Statistical Association*, March '36), published after the present book was written, fully corroborates my assumption. Taking the year 1900 as base with *real wages* in that year=100, Tucker gives for 1729-1739 an index of 67. (His index is very carefully constructed and takes into account the changes in habits of consumption.) This real wage (represented by 67 for 1729-1739) soon fell to 32.6 (1800) as a consequence of rising prices, while money wages remained the same. Later on real wages rose again, but it was not before 1870-1880, that they reached the level of 1729-1739, the next three decades brought an increase of about 50 per cent. (to 100:1900), but real wages decreased again during the war, but rose afterwards to 100 in 1927, and 112 (1935) with an accompanying decrease in working hours. The opinion that wages were quadrupled during the nineteenth century, must be considerably modified when we realise the very low level of wages at the beginning of the century, i. e. during the base year.

THE MECHANISM OF PHOTOSYNTHESIS AND NATIONAL OR WORLD ECONOMY

A statement by Dr. O. L. Inman, Director of the C. F. Kettering Foundation for the Study of Chlorophyl and Photosynthesis at Antioch College, Yellow Springs, Ohio, prepared at the request of Watson Davis, Director of Science Service, for presentation to the Temporary National Economic Committee, April 8, 1940

Our chief source of available power or energy is fundamentally the sun. This comes chiefly through heat, electric power derived from taking advantage of evaporation of water and its condensation at higher levels or by use of water power, and through the absorption of visible light energy by green plants. The use of coal, oil, gas, wood, etc. is drawing on the capital of by-gone days and this capital will keep on diminishing. Note the struggle in Europe for stored hydrocarbon compounds.

In my opinion, we have two ways of approaching the solution of this long time power policy: (1) to learn more about plant growth and to grow several hundred times the amount of vegetation we now grow, transforming much of this to a more condensed charcoal from which gas, oil, etc. may be made. Obviously, the study of problems of plant growth is of vital importance. The use of hydroponics as a technique, the developing of mutations by means of X-rays, ultra-violet light, radium, fast neutrons, or molecules such as colchicine may in the future increase yields. Also, the application of further knowledge in the field of genetics is surely of importance. For example, the rapid advance in the use of hybrid corn through the corn growing areas is now affecting economic principles.

The study of plant growth hormones which apparently control growing rates to a large extent is of much significance. (2) Another way is to solve the mechanism of how to fix with the tools we now have available, the carbon of carbon dioxide and the hydrogen of water into chemical compounds similar to methane or marsh gas and gasoline, or, by the addition of oxygen, to get sugar, woods, or fats, and, by the further addition of nitrogen, to get proteins and so on to thousands of possible compounds or molecules with energy stored ready for our use. In order to learn as much as possible about this storing of radiant energy the green plant is being studied. It can do a large scale commercial job under many varying conditions of environment. The green plant is about the only place available to us where energy is not degraded or changed to a less available form. When we know more, the chances are that man will solve the problem and set up his method of storing radiant energy from the sun in some way that is not the exact duplicate of the green plant. It may, however, be more efficient.

A recent review of studies of chlorophyll alone listed 400 papers covering the last six years. The number published on the whole problem of photosynthesis would be much greater than this. Rather than attempt to give you the names of all the chief research workers in this field, I shall list the laboratories where there are several staff members engaged in this work:

1. The Carnegie Institution of Washington with Laboratories at Stanford University, under the direction of Dr. H. A. Spoehr.
2. The Smithsonian Institution. Division of Radiation and Organisms, under the direction of Dr. Earl Johnston.
3. The University of Chicago Physics Department, under the direction of Dr. James Franck.
4. The University of Wisconsin, Madison, Wisconsin, under the direction of Dr. B. M. Duggar and Dr. Farrington Daniels.
5. The University of Minnesota, Minneapolis, Minn. under the direction of Dr. George O. Burr.
6. At Antioch College, Yellow Springs, Ohio, The Charles F. Kettering Foundation, under the direction of Ondess L. Inman.
7. Recently a few men at Dr. E. O. Lawrence's Laboratories, University of California, Berkeley, California and at Massachusetts Institute of Technology have begun work in this field.

The above list does not include approximately a hundred or more investigators who have contributed one or more papers in this field in recent years.

In Europe Dr. Hans Fischer's Laboratories at Munich, Germany, and Dr. A. Stoll at Basel, Switzerland, are probably the most active now. Then there are laboratories in Russia, Japan, England, France, and Italy, which do some work in this field.

A rough estimate of the amount of money budgeted in 1940 for this work in the United States would be about \$250,000-\$300,000 annually. In 1930 I should estimate about \$150,000 was spent in this direction. If necessary, I could give you the names of almost every individual engaged in this research, but I felt this was too detailed for your purposes.

The committee might like to know just how large a problem this is. The best estimates are that the energy reaching the earth from solar radiation each year is equivalent to that received from burning 4×10^{22} tons of anthracite coal. From this source we could draw plenty of available energy for all our needs.

I believe one thing should be clear and that is the problem of photosynthesis is mainly a "power problem" on a large scale. If and when the energy of the atom is tapped, part of the power problem might be solved. There is, however, still use for the green plant to furnish food in forms suitable for man and the animal kingdom, and there are literally thousands of compounds found in green plants which still need to be synthesized in the laboratory. It is perhaps true that we can eventually duplicate all these things, but it will probably be several million years before we can hope to duplicate most of the work of green plants. As far as energy is concerned a knowledge of the mechanism of fixing radiant energy in hydrocarbon compounds would be good. When we have really solved this problem we may need to derive energy from water power to produce atomic hydrogen by decomposition of water or molecular hydrogen and then reduce CO_2 to some $(\text{CH})_n$, $(\text{CHO})_n$, $(\text{CHON})_n$, $(\text{CHONPS})_n$ or other similar compound with suitable available energy in compact form. In this manner, tremendous power might become immediately available without resort to green plants. At the present time we are mostly in the theoretical stages of producing available energy by this latter means, but the stakes are so high that it is of clear cut importance to undertake such work.

Further than all this, while working on all these problems by-products are showing up all along the line. For example, in trying to extract the green pigment chlorophyll from the plant in an unchanged condition the plants must be dried carefully. It is clear that this careful drying also preserves food values better and we now have dehydration applied to alfalfa for animal feeds. In other words better ways of preserving the food value found in fresh green plants is a by-product. Also in trying to synthesize chlorophyll many new chemical compounds have been developed and some of them may prove valuable in medicine or industry. The use of radiation in photosynthesis studies gives us more knowledge of the effects of radiation on plant and animal growth and on chemical molecules used commercially in hundreds of ways.

In final analysis man has been taking for granted that he can in some way keep on depending on deriving energy or power from our capital stores of coal, oil, and gas. If he waits until he no longer has these stores, he is likely to find it is a long time research program and he was several years too late in beginning his work.

O. L. INMAN.

ATOMIC POWER

A statement by Dr. M. A. Tuve, Department of Terrestrial Magnetism, Carnegie Institution of Washington, Washington, D. C., prepared at the request of Watson Davis, Director of Science Service, for presentation to the Temporary National Economic Committee, April 8, 1940

Fifty years of research on the constitution of matter and the internal structure of the atom, supported and carried out for philosophical reasons quite unrelated to so-called practical objectives, has brought to light a great store of potential energy in every material body, tremendous in amount but until recently quite inaccessible. This discovery was only one of many unexpected by-products of atomic research. Another illustration occurred a year and a half ago when a special type of artificial transmutation reaction ("atom-smashing") was discovered in uranium and thorium, a reaction evidently possible only with the heaviest atoms in the atomic table. This very specialized reaction, for the first time, gives promise of making atomic energy available for use in the form of heat. Recent experiments indicate that the straightforward technical problem of separating two varieties of uranium atoms, increasing the concentration of one variety from two-thirds of a per cent to 10 or 20 per cent, is a remaining difficulty to be surmounted. This type of reaction at best will tap only an infinitesimal fraction of the total atomic energy around us, but it shows that another unexpected development in the future might put at our disposal a large amount of power derived from atomic energy. Two years ago "atomic power" of any kind seemed fantastic. Today it appears that the only hope for tapping large amounts of atomic energy lies in the possibility of discovering in the future a mechanism for atomic annihilation.

Atomic power from uranium gives us no promise at present of replacing coal and oil on a large scale, especially because of the scarcity of high-grade uranium deposits. Nevertheless it might have great future importance in specialized applications on not too small a scale, because a ton of the active component of uranium evidently will yield as much energy as 2,000,000 tons of coal. Plenty of uranium exists, as it amounts to one part in a million of the Earth's crust, or an energy equivalent of forty pounds of coal for every ton of rock. This is possibly a large reserve of energy for future use, but its wide dissemination means a very high cost to make it available.

Perhaps the chief point to emphasize in this connection is the importance of supporting fundamental research programs which have no immediate practical objectives, as a part of our social organization. In a democracy like ours it is encouraging to see that support can be obtained for long-range research, as exemplified by the National Cancer Institute and by some of the State Universities.

(Signed) M. A. TUVE.
M. A. Tuve.

HUNDRED-MILLION-VOLT, FORTY-NINE HUNDRED-TON ATOM SMASHER MADE POSSIBLE AT UNIVERSITY OF CALIFORNIA THROUGH \$1,150,000 GIFT FROM ROCKEFELLER FOUNDATION

Copyright 1940 by Science Service.

BERKELEY, CALIF.—The Rockefeller Foundation of New York City has given the University of California \$1,150,000 for the construction of a new and much larger cyclotron or atom smasher.

The plans for the new cyclotron call for a mechanism, or a fine integration of mechanisms, that will produce energies in excess of 100 million volts, as compared with the 33 million volts produced by the University's present 60-inch cyclotron.

The weight of the new cyclotron will be 4,900 tons, or more than 20 times heavier and bigger than the present instrument.

The new cyclotron will resemble the present medical cyclotron, but in details it is planned to be the most distinctive engine of its kind in the world. The designers in the University's radiation laboratory state that, because it is the first of its size ever planned or even contemplated, its actual operation may compel changes that cannot be predicted at present.

Technically, the new cyclotron is expected to show, in a quantity sufficient for observation, the types of phenomena observed in cosmic rays. More simply, its primary objective is to study new regions in the atom, which itself is an infinitesimal planetary system. More simply still, it will endeavor to wrest from the atomic substances that make up all matter the secrets of the energies that make plants and animals grow.

The initial operation of the new cyclotron will call at once into play some 50 million volts of energy, or 17 million more than the maximum noted thus far for the medical cyclotron. Nothing is known of the potentialities of cyclotron operation beyond this present maximum, and the scientific world is waiting to see what it will reveal.

[From the files of Science Service]

SUMMARY OF U. S. WEATHER BUREAU WORK IN LONG-RANGE FORECASTING

A Statement by Dr. C. G. Rossby and L. F. Page, U. S. Weather Bureau, Washington, D. C., Prepared at the Request of Watson Davis, Director of Science Service, for Presentation to the Temporary National Economic Committee, April 8, 1940

(a) In the field of "short" long-range forecasting experimental five-day forecasts have been made during the last two years, based on a combination of statistical studies, synoptic techniques and physical theory of the general circulation of the atmosphere. These forecasts have been subjected to rigid verification tests and have lately become sufficiently successful to warrant a broader try-out. It is accordingly planned to organize a special group which will devote itself exclusively to the preparation of such experimental forecasts for distribution to the individual district forecast centers where they may be used as a guide by our district forecasters in the preparation of the so-called weekly outlooks.

In the field of "long" long-range forecasting a critical survey has been made for possible methods of approach, without discovering any method which can be adapted directly to forecasting in the United States. Statistical studies of seasonal weather in the U. S. as related to previous departures from normal in other parts of the world have been carried out with no more than slight indications of factors which might have forecasting value but considerable progress has been made in defining trends in temperature and precipitation for the different regions of the U. S. and other parts of the world.

(b) Further progress seems most hopeful through an increased understanding of the general circulation of the atmosphere—the maintenance of the semi-permanent centers of action, for example, which determine the paths of individual storms. A single index of the strength of this circulation has been tentatively related to local weather occurrences and it is hoped that this index will provide a means of integrating apparently conflicting trends and fluctuations in different parts of the world into a world-weather pattern. Although some statistical

methods may be available for the same purpose, much more reliance can be placed in results which are founded on a physical explanation of factors which may be used in forecasting.

(c) (1) Experimental five- and ten-day forecasts in cooperation with M. I. T. under the direction of Profs. Sverre Petterssen and H. C. Willett of that institution. (2) Studies in the mechanics of the general circulation under Dr. C. G. Rossby of the Weather Bureau, combined with statistical studies of the relation between circulation patterns and simultaneous weather conditions, under the direction of Mr. L. F. Page of the Weather Bureau. (3) Correlation of weather in the U. S. with preceding conditions in other parts of the world, by Mr. R. H. Weightman of the Weather Bureau. (4) Determination of trends in temperature and precipitation, under the direction of Mr. J. B. Kincer of the Weather Bureau.

(d) The Weather Bureau is spending approximately \$30,000 on research directly related to long-range forecasting during the present fiscal year.

PROSPECT OF LONG-RANGE WEATHER FORECASTING

A Statement by Dr. C. G. Abbot, Secretary, Smithsonian Institution, Washington, D. C. Prepared at the Request of Watson Davis, Director of Science Service, for Presentation to the Temporary National Economic Committee, April 8, 1940.

This subject may suggest two branches. First, the extension of present forecasts from 2 days to 2 weeks. Second, to accomplish forecasts of temperature and precipitation for seasons and even years in advance. Both projects I consider to be practicable.

First: In the year 1936 I discovered that when short sequences occur of increasing or decreasing emission of radiation by the sun, they are followed for as much as 2 weeks by definite patterns of weather departures. These patterns differ at different stations and in different months of the year, but they appear to be stable for many years at a given station for each month. These patterns are generally opposite, like the right and left hand, following respectively rising or falling intensity of solar emission. Though the solar variations are only of the order of 1 per cent, the differences in temperature brought about by rising radiation as compared to falling radiation are of the order of 10° or more Fahrenheit. These are in fact major changes of weather, and are evidently governed by the sun's variation. In order to use solar variation as a predicting element it would be necessary to increase the number of "solar constant" observing stations, now only 3 in the world, to perhaps 10, for it would be necessary to get excellent determinations of the sun's condition every day. This expansion of observing program would cost about \$200,000 per annum.

Second: In the year 1935 I discovered 12 long periods in solar variation, ranging from 7 to 273 months in length. Seven of these periods have lately been strongly confirmed by Dr. Sterne of Harvard through statistical methods according to the theory of Least Squares. Three others of them I regard as certain, or 10 in all.

Meteorologists have seldom been successful with studies of periodicity. A proposed period may go on very well for a few months or years and then change in phase.

In studying the connection between the 10 periods of solar variation and precipitation and temperature, changes of phase are encountered also. But it is believed that the cause of these changes of phase has been discovered. Predictions of both temperature and precipitation have been made for several stations for 5 years in advance, by a synthesis of the effects of these solar periods. These predictions come true approximately 70 per cent of the time, and appear to be as good after 5 years as in the first year. The method is not fully perfected, but these preliminary results give promise that very useful forecasts for at least 5 years in advance may in due time become practicable. The method involves no appreciable expense. At all events the work already done shows that the variation of the sun, always hitherto neglected, is the main cause of departures from normal temperatures and precipitation at all stations.

A Statement by Dr. Charles F. Brooks, Director of Harvard University's Blue Hill Meteorological Observatory, Milton, Mass., Prepared at the Request of Watson Davis, Director of Science Service, for Presentation to the Temporary National Economic Committee April 8, 1940

Progress in long-range forecasting research in the United States is exasperatingly slow at present, owing to lack of sufficient funds to permit an adequate attack on

this world-wide problem. For daily forecasting it is practically enough to know what the weather is over and near the United States; for forecasting a week in advance, conditions far outside the limits of the country must be known, while for seasonal forecasting a knowledge of world weather is required. Whether or not the causes of variations from week to week, month to month or season to season are understood, no long range forecasting can be successful without thorough knowledge of the manner in which the atmosphere interacts over wide areas or over the entire earth to produce the local abnormalities. Since your telegram refers to long-term agricultural and other planning, I shall confine my further remarks only to long-range forecasting embracing a season or a year or a term of years.

Slow progress is being made in studies of world weather, to learn how the seasonal weather in the United States follows marked abnormalities here or elsewhere in the previous season or seasons. It has been found that conditions in the southern hemisphere indicate subsequent abnormalities in the northern hemisphere more often than do antecedent conditions in the northern hemisphere itself. And it has been found that autumn weather conditions in the tropical Australasian region when markedly abnormal will indicate the general character of winter rainfall over the northwestern plains and northern Rockies and over Florida and the neighboring portion of the West Indies. A trial forecast of the winter precipitation for Montana, 1939-40, was made and proved successful.

Seasonal weather maps for the entire world should be made, to learn why there is such a relationship, which has been established beyond reasonable doubt on statistical grounds. The statistics of the relationship should be extended to a longer period of years and tested for areas about the centers already established. Other groupings of months than the standard seasons should also be compared.

Supplementary charts of the extent of polar ice, of snow-cover, and the distribution of the surface temperatures of the oceans are needed before the abnormalities on the seasonal weather maps can be explained.

The departure of solar radiation from normal is also required. Studies are in progress based primarily on variations in solar radiation from which certain periodicities are appearing that seem to have their counterparts in weather trends. Also certain weekly, monthly, and seasonal weather abnormalities seem to follow variations in the sun. If these apparent relations are real, others of the same sort should appear on world weather maps. Some studies seem already to have shown such.

Statistical studies of cycles or sequences at particular places have been made, and with results that encourage further investigation. They are perhaps sufficiently definite to permit long-term planning in a broad way; but their value and one's feeling that they could be depended on would be enhanced if they could be related to the general abnormalities and their causes revealed on seasonal world weather maps.

Leading (or lonely) U. S. investigators are (*alphabetically arranged*): C. G. Abbot, Dinsmore Alter, H. Arctowski, T. A. Blair, L. E. Blochman, H. H. Clayton, H. W. Clough, G. F. McEwen, L. F. Page, C. D. Reed, I. I. Schell, R. H. Weightman.

Annual expenditures for research on this problem should cover the following: (1) Funds for each of the above and others with ideas to develop his ideas and bring them to an adequate test. (2) A centrally directed fund for world weather mapping by months and sequential combinations of months, and for a study of these by dynamic and statistical meteorologists. (3) A fund for thorough study of all scientific attempts at long-range forecasting that have been made anywhere in the world. (4) A fund for the establishment of weather stations in the larger areas of the earth's surface that are currently unreported, esp. in the South Pacific and the Antarctic.

Item (1) should have \$20,000 at least; item (2) should have \$20,000 at least, and preferably \$50,000; item (3) would require \$5,000 to \$10,000; item (4) would take \$100,000 to \$1,000,000 a year, depending on the adequacy of coverage. The total would be at least \$200,000 annually for any adequate attack on the problem of long range forecasting; and such an appropriation should be continued annually and increased. The amount might settle down to about \$1,000,000 a year at the end of 20 years, by which time seasonal, annual, and term of years forecasts should be established on a routine basis for all parts of the United States.

I feel certain that long-range forecasts are possible for the United States. The problem is no easy one and would take much work at great expense to solve to a generally useful point. The value of such forecasts, however, would far exceed

the cost. Therefore, I think it would be true national economy to promote the necessary investigations with adequate appropriations.

Sincerely yours,

(Signed) CHARLES F. BROOKS,
Charles F. Brooks.
Professor of Meteorology, and Director.

**A PRACTICAL APPLICATION OF KNOWLEDGE DERIVED FROM THE STUDY OF PLANTS:
VITAMIN K CHEMOTHERAPEUTIC ATTACK ON DISEASE: PNEUMONIA, SYPHILIS,
MALARIA**

**A Statement From Dr. Walter Simpson, Miami Valley Hospital, Dayton, Ohio,
Forwarded by Dr. C. F. Kettering, to Watson Davis, Director of Science Service
for Presentation to the Temporary National Economic Committee, April 8, 1940**

In 1929, Doctor H. Dam, of Copenhagen, observed that chicks raised on certain artificial diets became anemic and suffered from hemorrhages. After extensive experimentation he discovered that the hemorrhages and prolonged clotting time of the blood were due to a lack of a new fat-soluble factor, which he named vitamin K. Doctor Dam and his associates found that this anti-hemorrhagic vitamin is widely distributed in green leaves and vegetables, with an abundance in alfalfa leaves. Doctors Almquist and Stokstad reported in *Nature* in 1935, that the addition of 0.5 percent of dry alfalfa to the diet prevented the hemorrhagic symptoms. Hence one of the chief sources of this vitamin has been alfalfa.

More recently, chemists at St. Louis University and the University of California have identified chemically the active principle of vitamin K contained in alfalfa and other green vegetables such as spinach and cabbage. This has resulted in a much more stable and reliable product which can be manufactured at relatively little cost. Now, in thirty minutes, a skilled medical technologist can tell whether or not a person is deficient in vitamin K by determining the prothrombin time of a tiny sample of blood taken from an arm vein. The prothrombin deficiency and hemorrhagic tendency is most common in jaundiced persons, particularly newly born infants and in those adults who become jaundiced because a gall stone is obstructing the flow of bile through the gall ducts. The old mosaic law, as revealed in the book of Genesis, forbade circumcision in infants during the first eight days after birth. Again modern science finds justification for another old belief based upon long observation, in the recent studies by Doctor Armand Quick, of Milwaukee, Doctor H. B. Smith, of Iowa City, and Doctor Albert N. Snell, of the Mayo Clinic. These medical researchers have found that two to three percent of newly born babies are bleeders because of vitamin K deficiency. This bleeding tendency is most prevalent during the second to the fourth day of the baby's life. The administration of vitamin K promptly eliminates this hazard.

No longer need the surgeon hesitate to operate upon the jaundiced patient because of the previously great danger of fatal hemorrhage following the operation. The bleeding tendency can now be abolished overnight by injections of the new synthetic vitamin K (2-methyl-1, 4 naphthoquinone).

CHEMOTHERAPEUTIC ATTACK ON DISEASES

Pneumonia is now regarded as the third great killer of mankind. The advents of new chemotherapeutic agents, such as sulfanilamide and sulfapyradine has already produced such remarkable results in curing both the pneumococcus and streptococcus forms of pneumonia that it seems very likely that pneumonia will soon occupy fourth or fifth place among the causes of death. The great physician, Sir William Osler, once referred to pneumonia as the friend of the aged. Pneumonia strikes particularly at children and old people. But pneumonia can no longer be called the friend of the aged, because the new chemical agents are just about as curative in old people and in children as they are in robust adults. In those cases of lobar pneumonia that do not respond promptly to sulfapyradine and similar chemical compounds thirty-three different types of anti-pneumonia serums are available as additional aids.

Since the discovery of Doctor Paul Ehrlich's magic bullet (606) many new types of organic arsenical compounds have been developed for the everlasting warfare against syphilis. Some of the newer arsenic and bismuth compounds are much more effective and much safer than Ehrlich's salvarsan. Experiments now under way indicate that by combining relatively large doses of arsenic compounds with artificial fever it may be possible to reduce the minimum time for the treatment of syphilis from eighteen months to a few days. When the treatment for syphilis becomes simpler and cheaper we will be well on our way towards the eradication of this great destroyer of mankind.

Ever since the Spanish conquerors of South America discovered that the Peruvian Indians had long used an effective remedy against malaria which they derived from the bark of cinchona trees, quinine has been the sovereign remedy for malaria. In the past few years quinine has been largely displaced by the new chemical compound known as atabrine. Now it appears that five days of treatment with atabrine is even more effective than weeks and months of treatment with quinine.

Many more new chemotherapeutic agents might be mentioned, but these three examples will suffice to demonstrate that while eighty percent of the people of the world are now engaged in a campaign of destruction, a small army of chemists and physicians is struggling incessantly to save the lives of men.

HARVARD UNIVERSITY

GRADUATE SCHOOL OF BUSINESS ADMINISTRATION

GEORGE F. BAKER FOUNDATION

ELTON MAYO
Professor of Industrial Research

SOLDIERS FIELD, BOSTON, MASSACHUSETTS, *March 28, 1940.*

Dr. WATSON DAVIS,
Director Science Service, Washington, D. C.

MY DEAR DR. DAVIS: There are three outstanding present and future problems of industry and general living. So far as I know the amount of research being done on these problems is so small as to be negligible. The three problems are:

I. The problem you name; the development of better human relations in industry and generally.

II. The problem of executive authority.

III. The problem of unemployment.

My statement that little or no research is being done on these important problems may seem at first surprising. I hope to show you that it is only the obvious aspects of these difficulties that are being studied and that the various inquiries deal only with palliative measures for the symptoms and are not concerned to diagnose the malady.

I. HUMAN RELATIONS IN INDUSTRY AND GENERALLY

For some fourteen years we have been directly interested in an investigation at the Hawthorne Plant of the Western Electric Company and throughout this period we have collaborated closely with the company officers in research. The course followed by the inquiry and the results obtained have been described in a book recently published by us, *Management and the Worker* (by F. J. Roethlisberger and W. J. Dickson, Harvard University Press, 1939). This book has not yet been reviewed by the more serious publications although we have been permitted to see certain reviews in proof. It is an interesting fact that we published an edition of one thousand copies, October last, at \$4.50 a copy and that by the end of February it was completely sold out. It is also interesting that the book has attracted the interest not only of management but also of Mr. Harold J. Ruttenberg and the intelligent organizers of the CIO. It would seem that both these groups, the management and the CIO groups, are willing to accept our findings as representative of the actual situation on the working line in industry.

In brief, the inquiry began with intensive studies of the individual worker—physiological, psychological, psychopathological. Step by step over a period of six years we were driven away from an intensive study of the individual worker

to a study of the individual as related to the informally ordered group of workers about him. The psychoanalytic method of digging deeper and deeper into the particular individual's condition, though exceedingly interesting and in a few cases relevant, proved entirely fruitless for the main inquiry. Nevertheless, the whole investigation and the manner of its conduct owe a heavy debt to Asklepios and to psychopathology.

The science of economics tends to adhere to assumptions made in eighteenth-century France and nineteenth-century United States, the assumptions being, first, that society consists of individuals and that their organization is predominantly economic; second, that the individual is motivated mainly by his material interests; third, that the individual thinks logically in the service of these interests. We have found that in industries it is generally and almost invariably true that the individual is actuated chiefly by a passionate desire for an intimate and routine relation with his fellows at work. It is our general finding that in the service of this passionate desire he will sacrifice not only what seems to be his own material interests but also his right to independent and logical thinking. It is, in other words, the chief character of the human scene that the individual adapts to his work by subordinating his own sentiments to the sentiments demanded by a routine association with his fellows and that, as adequately as may be, he adopts their ways of thinking and living as part of his own. This indeed is society as we find it in industry.

Now it is the habit of industry and economists and psychologists and psychiatrists to ignore this very real informal group organization and to behave as if one exercised control over the mass by relating the control directly to the separate individuals in it. This is not true and it leads to grave misdirection of research. It leads in fact to what I call a psychological "rat-hunt."

First, the psychologist is trained to search for I.Q.'s or for particular vocation "sets." I am not denying that such inquiries have their value but in effect it becomes a search for a "structure" (traceable possibly to the biological genes) which neglects completely to inquire into, or to take account of, the balanced relation between individuals in an organization. Yet it is this balanced relation which is the important fact for the administrator. In other words, the inquiry is directed at the structural and neglects the dynamic completely. Since at the moment our modern problems all relate to the dynamics of social control, these studies, however interesting in themselves, become in the main irrelevant.

Second, psychiatry. Here also is another instance of the same technical error. In his ordinary practice there are brought to the psychiatrist those persons who quite obviously have failed to establish a harmonious and happy relationship with other people about them in the society. Frequently, though not always, the failure is serious because if any ordinary adjustment will serve to aid the individual it is contrived for him before he drifts into the hands of the psychiatrist. By reason of the work he is required to do, the psychiatrist is therefore in part disqualified for actual social study. Indeed, the ordinary practitioner of medicine is in this respect better qualified because he is required to handle many such cases and does so admirably; he does this work so well that he stops many individuals on their way to the psychiatrist and contrives for them a happy solution of their troubles. The psychiatrist therefore is by his work conditioned to expect that behind the social ineptitude that he studies there will be a structural defect in which the unbalance originates. He therefore, when his attention is turned toward industrial or social inquiry, charges into action with this as a guiding idea—the idea, namely, that it is his business to discover those persons who do not easily adapt and to make special provision for them. One would have expected that psychoanalysis, with its close study of infancy and adolescence, would have effectively changed this point of view. Curiously enough, the psychoanalysts are no better in this respect than are the psychiatrists. For them, the structural defect is traceable to an infantile trauma or a distortion of attitude due to a defect of infantile environment. But once they have established this as their main tenet their attitude becomes in other respects identical with that of the ordinary psychiatrist. In other words, their main idea resembles far too closely the rat-hunt principle of looking for individuals with structural defects in order to throw them on the ash heap.

I am happy to say that I know one exception to this rule. Dr. J. S. Plant, in Essex County, New Jersey, has conducted for many years an inquiry into delinquent children which, if one makes allowances for differences in situations studied, moves step by step very closely with our studies of the actual balanced relation between persons organized in groups, which is the main character of our industrial and social life.

these fields. I have already mentioned, I think, two names. I have also described our own struggle to develop such inquiries. Beyond this it is a melancholy fact that neither here not in England or in France do I know of anyone who is actively engaged in developing research of the type I describe. For years here we have hoped that some one or other of the universities would undertake investigations distinct from our own, which would result in a valuable comment or critique of what we have been struggling to do. I cannot report anything even of the smallest of beginnings. Here we are hampered by lack of funds. We can pick up almost any number of exceedingly intelligent young men eagerly interested in this kind of inquiry. I then find that the funds we should need to hold them in the work for the five or six years that would be necessary are not available. We have done the best that we could do in the circumstances.

I should like to suggest that you consult certain other persons upon the statements I have made. First, my colleague, Dr. L. J. Henderson, Morgan Hall, Soldiers Field, Boston. Henderson is chairman of a special committee appointed by the National Academy of Science and the National Research Council, which is just completing a report on "work in industry." This report will cover very thoroughly the topics I have briefly mentioned in the first section of this letter.

Dr. Henderson has also conducted for some years here a sociological class, Sociology 23, which has endeavored to give to students some species of dynamic conceptual scheme in social or industrial study. Dr. Henderson has been the chief lecturer but has brought in physicians, administrators, investigators, of all types, the business of each one being to present to the class some actuality of social fact which he has himself studied and for which he has been, at least in part, responsible. This class, after some years of comparative neglect, is now beginning to attract the active intelligences amongst the undergraduates.

Mr. Chester I. Barnard (540 Broad Street, Newark, New Jersey), President of the New Jersey Bell Telephone Company, not only has a most unusual interest in some of the problems I have described but has also some knowledge of the work we have been doing.

Mr. Harold J. Ruttenberg (Research Director, Steel Workers Organizing Committee, 1500 Commonwealth Building, Pittsburgh, Pennsylvania) in the course of his work for the CIO has come to conclusions with respect to the human facts at the work bench which are capable of being closely related with the facts emerging from the Western Electric inquiry.

Professor John G. Jenkins (University of Maryland, College Park, Maryland) has become interested in the work we are doing. I believe that he is at present the Washington representative on the National Research Council of the Division of Psychology and Anthropology.

Your final question is that as to the cost of such researches. On the one hand my feeling is that in view of the present incapacity of psychologists and economists to provide any diagnosis of the ills we suffer no outlay could be too great, if the right type of inquiry can be instituted. Once again, however, I have to report a melancholy fact: It is clear that this work in its actual operation must be accomplished by young men. At the moment there are exceedingly few young men who have been given the right training, and the slipshod discussions of political and economic theories of the last century have so distorted the capacity for vision in many instances that a slogan is more the metier of a young man than genuine inquiry. There are a few who have been appropriately trained at the moment—I regret to say, very few. I believe that these inquiries should be begun wherever possible but that wherever they are begun the provision for appropriate training of intelligent youngsters should be considered to be almost as important as the inquiry itself.

Written in haste at your request—

Yours very sincerely,

EM/BB
Please pardon corrections.

[From the files of Science Service]

BACKGROUND OF CONFLICTS

Excerpts from a statement by Lawrence K. Frank, Josiah Macy, Jr., Foundation, New York, prepared for Science Service

The usual interpretation of wars and other international conflicts is in terms of urgent political and economic struggles for wealth, power or other similar motives. Suppose, instead, we look upon each nation as having a past history expressed in their memories and traditions and ideas and beliefs. Each nation, in its present state, is derived from a past, sometimes very remote. Each group of people has developed in that past specific ways of living, thinking, believing and feeling which still control their lives. These may be wholly inadequate or unsuitable to their situation today. This past experience of a people is transmitted from one generation to the next by parents, teachers, and others who instruct the young. While the people exist in today's world, nevertheless they are living primarily in the past.

We are governed to a large extent by tradition, by what our ancestors have done. Anthropologists and ethnologists who study they many different ways in which people have organized group living and regulated their lives call these persistent memories and traditions "culture."

They point out that in this prior history or the culture of peoples, one can usually find the source of their internal difficulties and perplexities as well as the clue to their external conflicts.

Let us look for a moment at the situation in the life of a single individual. Here we are beginning to realize that each person's conduct is an expression of what he experienced and felt in his past, usually long forgotten and buried beyond his recognition. We usually interpret his behavior in terms of various supposed motives, saying he does this because he is angry, or jealous, or ambitious. But we may look upon his conduct as arising from his past history, which makes him do just what we observe today under the direction of this long forgotten childhood.

What difference does that make? Suppose we stop thinking that society does something because of supposed causes or social forces, and that the individual does something because of specific motives. Suppose we say, instead, that a people, as well as each individual, are coerced and dominated by past history and traditions and memories. Suppose we recognize also that feelings have been created by those past experiences that are being expressed today? What then?

It would change the way we look at life. We are learning that as soon as a people or an individual discover that they are being ruled by this forgotten past, as soon as they realize that their prior experience and traditions and their feelings about the past are operating to control their lives today, this awareness or consciousness of their past may actually free them from such control. We have long been told that we cannot change human nature. But now we are discovering that what we call human nature is just an expression of what an individual has experienced and felt. It can be changed just to the extent that we change our cultural traditions and modify what individuals experience in their childhood.

THE AMERICAN ROLLING MILL COMPANY, MIDDLETOWN, OHIO

Subject: Plan for handling hot mill employees in connection with new finishing mills.

1. We do not expect to be able to find jobs for employees who have been with the company for less than one year.
2. Jobs will be found on new finishing mills for as many men as are necessary for their operation and every effort will be made to place as many as possible in other positions in our various plants.
The employment department will have charge of placing men.
3. Men who are not placed will be given half pay for as many months as they have years of service but not more than six months and with a minimum of \$50.00 per month.
4. No special payment as outlined in Paragraph Three will be given to men who are placed in any of our plants.
5. Any man who accepts a position in our plants, but decides within a period of 30 days that for some reason he is not able to go on, will receive the payments as outlined above.
6. Continuous service with full insurance will be carried for the period mentioned in Paragraph Three on all men who are not placed in our plants.
7. If an employee gives up a job and received payment as above and then starts with the company later his special payments will cease and he will not receive them again if he should leave the company's employ a second time.
8. If requested, the company will be glad to assist in placing men with other companies if positions cannot be found in our plants.

WAR AND THE STEEL GHOST TOWNS

By Harold J. and Stanley Ruttenberg

Compliments of C. U. O.

(Taken from Harper's Magazine, January, 1940)

"It's started," a lean-faced, bedraggled, unemployed steel worker announced excitedly. "I mean the war. Hitler's marching into Poland. I just heard it on the radio," he explained further to a group of sullen men loafing on South Mill Street, across from the relief headquarters in New Castle, Pennsylvania. The dead silence broke. One man whittling a stick dropped it. Another sitting on the curb got up and walked to the middle of the group. Someone asked hopefully, "Do you think the mills'll start up?" Everyone began to speculate on this possibility.

Within an hour news of the outbreak of war in Europe was all over town. Rumors of good things to come began to fly fast and furiously. This is going to be a long war. There's going to be a big boom all over. The mills, factories, and mines everywhere will soon be needin' men. There'll be work and plenty of jobs. A few days later the Mayor of New Castle solemnly told us that U. S. Steel had received a large order from Japan and that the obsolete hand-mills would soon be reopened because the modern strip mills were being taxed to capacity. We heard about "the order from Japan" from a newsboy, a waitress, from conversations in the street, and from almost everyone we met.

More hopes were being built on equally plausible rumors. Someone heard from some official at the mill that the war had caught the strip mills unprepared. Canadian tinplate supplies were low. The German submarines had cut off Canadian can manufacturers from their regular supply of Welsh tinplate, at least for six months until England could organize its convoy transportation. Oldtimers in the tinplate trade were saying that the food packers would rush to buy up one hundred per cent of the 1939 vegetable and fruit crops, pack them in every tin can they could lay hands on, and store from twenty to ninety per cent of the several food packs until prices went up. Before the war was two weeks old everyone in town had convinced himself that U. S. Steel would have to reopen the hand-style tinplate mills, which had been abandoned for good, to meet these multitudinous demands for tinplate, despite the fact that hand-rolled tinplate costs were five to twenty dollars a ton higher than on the automatic strip mills.

Dreams began to be dreamed—not by workers alone, but by everyone in town. We'll get the gas turned back on. We'll pay the back rent and won't be kicked out. The kids can get new school clothes. I'll buy the wife a new dress. Dad won't have to wear that sloppy old hat no more. We'll fix the car and buy a license for it. The milk bill can be paid and we'll start to get milk again each morning. Our rent collections will go up. Business will be better. The workers will start buying all the things they need and have been without. New Castle will be back on its feet in no time.

"Glory hallelujah!"—in brief, that is how World War II was greeted in New Castle. And understandingly so, because private industry had deserted the town; new machines had thrown 5,700 of its workers on the ash heap; its industrial employment had declined sixty-four per cent since 1927; fifty-two per cent of its fifty thousand people were dependent upon government aid for subsistence (with another twelve per cent trying to get relief or WPA jobs); the State and Federal governments had turned a deaf ear to the workers' call for real help, and the 76th Congress had limited their last hope for employment by cutting WPA. With its future hopeless, despairing of any aid from private industry or government (except meager relief or WPA grants), New Castle succumbed to the war fever. And not in vain.

"M' added to 'Boo'— Thus the *Pittsburgh Press's* headline writer, twenty-six days after the war started, prefaced a front-page headline:

"GHOST' TOWNS IN DISTRICT STIR AS MILLS, MINES OPEN"

The story under the headline announced that one of New Castle's obsolete tinplate mills would resume operations, and 2,500 of its technologically displaced workers would be reemployed. Like the stranded people in other "ghost" steel

and coal towns, the people of New Castle cheered—though they must have guessed that the mill was being reopened for a limited and final time.

"Ghost" towns in coal have been chronic since the end of World War I, but in steel they are something new. In the past two years the steel strip mills, "a moving picture director's dream of the future of technology," had displaced 25,000 hand-mill workers and turned more than a dozen thriving communities into "ghost" steel towns. Overnight the "war boom" put new life into several of these, like New Castle and Martins Ferry, Ohio. Other steel towns that are still dead, their obsolete mills idle, their displaced workers unemployed, symbolize the nation's pressing economic problems that have cried out in vain for a domestic solution. The ghost towns that have been revived since the outbreak of war symbolize the way in which bombs over Warsaw can bring joy to workers, farmers, and industry starving respectively for work, higher prices and profits. The deadly parallel between these ghost steel towns and the country as a whole, afflicted with common economic ills that have not responded to domestic forces, both resuscitated for the time being by war in Europe, raises the question: "After the war boom, what then?"

When the extraordinary tinplate and other steel demands cease, the skilled hand-mill workers will be through, this time for good. Revived steel towns will revert to ghost towns. More steel communities will be added to the "ghost" category. In all the horrors of a post-war depression the country's pressing economic problems will be more acute, the plight of New Castle and the other ghost towns more tragic, and the necessity for domestic solutions inescapable. The war boom can only postpone the day when we shall have to come to grips with the economic ills it is temporarily solving. These ills are deep-rooted indeed. Distressed communities with stranded populations in the coal fields, depleted timber lands, copper, lead, zinc, oil, and gas districts, and textile centers have been the by-products of the exploitation of natural resources and the shifting of production centers. But in the steel industry ghost towns are the result of economic ills that permeate our national economy. Technological unemployment has reduced these steel towns to economic ruin.

II

The story of New Castle gives the picture of all the ghost steel towns, because their rise and fall resembles one another as closely as the play-by-play description of one football game resembles another. New Castle lies sixty miles north of Pittsburgh, midway between Lake Erie and the Ohio River, in the middle of the Shenango Valley. It was founded in 1798 by a small band of Swedish pioneers, who became prosperous farming the fertile fields of the valley.

At the time of the Civil War ugly coal tipples began to dot the landscape of the beautiful valley, rich meadow lands were torn up to uncover limestone, and the iron ore openings spit forth huge chunks of red earth. "Billy" Patterson, a farm boy risen to banker, transformed the peaceful Shenango Valley into a seething industrial district, put its coal, ore, and limestone—the main ingredients of iron and steel—together, and sold his outside interests to concentrate on expanding New Castle. By 1890 he gave the town one of the country's first integrated steel firms with a continuous chain from iron ore to finished products. Billy Patterson, having become an iron master and steel magnate, sported a walrus mustache in keeping with his reputation as "the father of New Castle."

The rise of New Castle was phenomenal. Despite the panics and depressions of the eighteen nineties, its population increased 144 per cent to 28,339, faster than that of any other town in the country. At the turn of the century over six thousand workers were employed in its steel and iron works and rod, wire, nail, and tinplate mills. The town proudly boasted having the largest tinplate mills in the world, and its rapid growth attracted several consumers' goods industries. Youngstown, Ohio, to-day's number three steel town, was then only a flyspeck on the economic map of the industry, and Gary, Indiana, to-day's number two steel town, still a swampy marsh along Lake Michigan. New Castle seemed destined to become the very center of the new steel world, until Billy Patterson retired and the town fell into the hands of a stepfather.

In 1898 J. P. Morgan & Company bought every important New Castle steel works, and apparently obtained from their previous owners an agreement not to reinvest their profits in steel works in New Castle that would compete with the billion-dollar Steel Trust—at least, such were the results. Seventy-four years old, Billy Patterson gracefully retired. All the other important steel men in town, except George Greer, moved away or invested their money elsewhere. Even Green, whom U. S. Steel put in charge of the tinplate mills, invested his

money in the LaBelle Iron Works at Stubenville, Ohio, and in other firms throughout the country. Thus ended the expansion of the steel industry in New Castle. For a while a few enterprising local business men tried to carry on the tradition of an ever-growing industrial community. But the people soon learned that their town was no longer run by local men; New Castle's new boss was an absentee owner.

That boss was Judge Elbert H. Gary. His first act was to throw fifteen hundred rod, wire, and nail mill workers on the streets, blame it on "labor trouble," and merge the rod, wire, and nail mills with similar operations elsewhere. It was soon evident that New Castle's absentee owner was not interested in developing the town but only in U. S. Steel's interests as a whole. Ruinous competition of Welsh tinplate having eliminated by the McKinley Protective Tariff on tinplate, that to this day gives American tinplate producers a monopoly in the United States, U. S. Steel, then settled down to making handsome profits from the New Castle tinplate mills until 1937, when technology made them obsolete. Gary acted on the idea that ownership of the steel and tinplate works entitled U. S. Steel to control the town. The results were soon evident. A glass company, founded in New Castle in 1849, moved to West Virginia. John Stevenson, Jr., who had played an important role in developing New Castle's tinplate works, dismantled his stately stone mansion on Lincoln Avenue overlooking New Castle; piece by piece he moved it twenty miles up the Shenango Valley to Sharon, where the mansion was reconstructed. In south Sharon Stevenson erected a large tinplate works, but as soon as it was completed the powerful U. S. Steel combine bought it, built a company town round the works, and named them the Farrell Works and Farrell, Pennsylvania, in honor of James A. Farrell, one of U. S. Steel's ranking officers.

Now only one force—the labor unions—stood between Judge Gary and complete domination of New Castle. His efforts to exterminate the trade unions in the tinplate mills failed in 1901 because of an esprit de corps pervading the workers and management. Behind this harmonious condition was a long tradition of collective bargaining that the skilled Welsh and English workers brought with them and that had been in practice in the New Castle mills from their beginning. George Greer, the manager of the tinplate mills, refused to round up a gang of strikebreakers. With head always erect, sharp eyes, and a distinguished goatee, Greer was a man of forceful independence and did not fit into Gary's military type of organization. But he was such an indispensable operating man that Gary was not free to oust him until July, 1908. The following July, 1909, Gary handed the tinplate workers' union an ultimatum to disband. Having seen the pottery workers' union shattered to bits three years earlier, the tinplate workers received the Judge's ultimatum stoically and closed down the mills. The pottery strike had shaken up New Castle, which had been a union town for years, because it was plainly observable to the townsfolk that U. S. Steel was behind the pottery firm. With Greer safely retired to his farm where he raised Shorthorn Durham cattle, Judge Gary imported strikebreakers and broke the strike in six months. Not until the rise of the C. I. O. in 1937 were New Castle's tinplate workers organized again.

Anger, especially among the workers, turned into a spirit of revenge. In 1911 the town elected a Socialist Mayor, Walter V. Tyler, who was a railroad brakeman. A split between the "wets" and "drys" facilitated the Socialist victory, but their capture of the city council was clean cut. Judge Gary's followers lost no time in getting the Republican legislature in Harrisburg to rip out the council of fifteen members elected on a ward basis that proved hard to control, and to install a commission form of government, with only four councilmen. The local paper editorialized:

"* * * the bitterness and *desire for revenge* that led up to the election of a minority mayor have been gathering volume for years. Petty jealousies, *lack of tolerance for the views of others* * * * found expression in this election."

The humble editor of the town's paper was telling Judge Gary that the workers had elected a Socialist Mayor to get even with him for taking their union from them. Mayor Tyler did a valiant job while his term lasted. Judge Gary saw that he never got another one. And when Walter V. Tyler was elected to city council in 1928 as a Republican he symbolized U. S. Steel's domination of every phase of New Castle's life.

III

Before World War I intervened, there were omens of New Castle's economic decline. In 1912 a stamping and enameling company failed. The next year, Youngstown, Ohio, already overshadowing its rival as a steel town, gleefully reported in the *Youngstown Vindicator*:

"With * * * the wealth of the city tied up principally in banking and other private financial interests, New Castle gradually commenced to feel the effects of its wealthy men's inactivity. Merchants * * * interested in the prosperity of New Castle pointed longingly to the vastly different spirit shown by the home capitalists of Youngstown who on selling their stock to the combine (U. S. Steel) * * * organized * * * independent companies. But * * * New Castle dollars went * * * to promote gold mines in the west, to build oil refineries in other parts * * * with little concern for the industrial advancements at home. The effects of this spirit were bound to bring bad results."

The bad results were postponed by the War, throughout which New Castle prospered. U. S. Steel added seven hundred and fifty more tinplate workers to its rolls, restoring half the number of jobs it had eliminated a decade earlier. The wheels of industry hummed until the advent of the post-war depression, from which New Castle has never recovered.

Like its rise, New Castle's fall has been phenomenal. During the prosperous twenties its population increased only eight percent while the nation's population rose sixteen percent. The Chamber of Commerce became alarmed about the loss of industries and jobs by 1927 and hired experts to make an industrial survey of New Castle, which showed:

"* * * You have * * * lost a number of plants * * * The time has come for * * * a program that will cover a period of the next few years. You are in real competition when you land an industry these days. * * * The program we recommend is:

"REPLACE LOST INDUSTRIES * * * the Car Works, the Rubber Plant, the Baking Company, the Knitting Mill, the Brewery, and the Stove Works (all left town). The Engineering Works in 1920 * * * had 452 employees * * * During the summer of 1927 they had 66 * * * It does seem as though there would be some way to save this important industry for New Castle * * *"

Spurred on by the loss of these firms that employed 3,340 workers the Chamber started a campaign late in 1927 to replace them. Not a single new firm was brought to town by 1930 when the depression set in. Gone was Billy Patterson and the spirit of local initiative. When a firm failed in Patterson's days he would solicit New Castle business men to subscribe for stock in a new firm to take over the bankrupt one, and loaned the money to those subscribers who could not raise it on the spot. New Castle's absentee overlord had long since snuffed out this enterprising spirit. When the car works closed early in the twenties and threw two thousand men on the streets, for instance, U. S. Steel did nothing.

But the Chamber's drive to replace New Castle's lost industries failed ignominiously because the townfolk expected that U. S. Steel was going to expand its New Castle operations and employ more workers. An officer of one of the pottery firms in town told us:

"In the twenties U. S. Steel bought a large tract of land adjacent to its property, and built a modern power plant with a much greater capacity than its operations required. Everyone assumed that the land was purchased and the enlarged power plant erected to take care of the open hearth furnaces and coke plant the Corporation was going to build."

Talk of this expansion created a wide-spread feeling that the Chamber was unduly alarmed about the loss of jobs, and that U. S. Steel "would take care of New Castle." As a consequence, the Chamber's drive fell flat because the townfolk did not get behind it.

Not until 1931, when U. S. Steel abandoned its Bessemer steel works, throwing twelve hundred workers on the streets, did the townfolk suspect that the company would not take care of New Castle. Some clung to the hope that the Bessemer steel works would reopen after the depression, although informed steel men knew that it was the victim of technological advances in the use of open-hearth steel where Bessemer was formerly used. In 1935 the works was dismantled; Bessemer steel had declined from sixty-seven per cent of the steel produced in 1900 to less than ten per cent. Technology dealt New Castle a body blow. The Chamber's ill-fated program was revived. By 1937 ten new industries employing 950 workers were brought to New Castle, and its future seemed less hopeless. But only for a brief period. In the fall of 1937 there came a second blow: U. S. Steel permanently abandoned the Greer tinplate works, displacing fifteen hundred workers.

Thoroughly alarmed now, the townfolk suddenly got visions of a "ghost" town. The Mayor led a committee of leading citizens to the Pittsburgh office of U. S. Steel. "Why didn't you build your continuous strip mill in New Castle, which

has the workers to man it and the community facilities to serve the workers, instead of building it in the wilderness of Irvin, Pa.?" the committee asked.

The reply, in effect, was: "We would have liked to honor New Castle with the Irvin strip mill, but we had to protect the interests of our stockholders. We can produce at Irvin anywhere from five to ten dollars a ton cheaper than we could in New Castle. Irvin is on the Monongahela River, interconnected by our own railroad with the Edgar Thompson works that supplies it with semifinished steel. Our Clairton by-product coke ovens are nearby and they supply Irvin with gas. Finally, we of course have the advantage of cheap water transportation down the Ohio River, as well as of our own railroad, to ship our finished products from Irvin. You understand, gentlemen, that building in New Castle was out of the question because of its disadvantageous geographic location. It is an inland town. Transportation costs in and out of New Castle are prohibitive."

All hope of U. S. Steel expansion in New Castle was gone. The committee returned home disheartened. The townfolk agitated for a canal from Lake Erie to the Ohio River, but their hopes for cheap transportation were soon drowned in the failure of the canal project. Geography had dealt New Castle another blow as a heavy industry town.

IV

Merritt Reynolds, a handsome, trim boy in his late teens, graduated as president of the 1939 New Castle High School class of 601 young men and women. Chosen with the other officers of the class as the most likely to succeed, he hunted for a job, any kind of work, put his application in at "a dozen places but they all drew blank." The auto repair shop located in the stables of Billy Patterson's old mansion didn't need any help. "Can't use anybody," he heard at the bronze plant, the potteries, the chemical works, everywhere he went. There was no use trying at the lone remaining tinplate mill, "'cause there's hundreds of tinplate men from the old Greer mills walkin' the streets." All Merritt Reynolds could find was a job as an extra usher in a movie house. Unable to make out on his part-time earnings, he went to the Knitting Mills building, now occupied by the relief offices. Here Merritt got his first opportunity, a chance to go to a CCC camp in Arizona. He took it, gladly.

Only one officer of the 1939 class got a job—as a bell hop at a hotel on strike by the A. F. of L. A year after graduating, the president of the 1938 class was still unemployed. The rank and file of the graduates found the going just as tough. Of the 513 graduates in 1937 three out of ten went on to school, two got jobs, while five out of ten could not find work. 554 graduated in 1938. Six out of ten joined the unemployed, two went on to school, and two got jobs. High School authorities will not know what happened to the 1939 class until next year, but one school official said "The 1939 graduates are not competing for private jobs, there are none to compete for, but fighting to get into the CCC."

Among the workers who once had a job despair is ghastly, hope more forlorn. "I'm whipped" a \$15 a day tinplate worker told us a few days after he was furloughed from a \$3.20 a day WPA job in August. "I can't make a livin' any more. The hand-mills are through. They're turnin' out more tinplate pushin' buttons in these strip mills than the whole lot of us could roll. I use' to make good money, and I saved some. Ma and I bought our home when we were married, got it all paid for, and now can't meet the taxes. We can't even get on relief 'cause my oldest boy and his family are livin' with us and he has a job drivin' a truck. A fellow can't get a job in town, everything is dead, and he can't go nowhere lookin' 'cause he's busted. I bummed a few bucks and traveled for two weeks huntin' work. It was no use. My youngest boy can't get in the CCC camp 'cause we ain't on relief, and can't get on. What's the use o' talkin'! How about settin' a fellow up to a glass of beer?"

Seven thousand families, sixty-four per cent of New Castle's population, are in the same boat. Few have the money to go elsewhere to seek a job, and those who do only discover that private industry is not expanding to take up the slack in jobs created by technology.

"SHAVE AND HAIRCUT—TWO BITS" is painted on the window of a barber shop in the workers' section of town. The barber explained: "I charged the regular price until a few months ago, but I couldn't make out. My good customers didn't have the cash and charged it. I did their work because I had nothing else to do and to keep them as customers if things ever pick up around this place. I was about forced to close the shop when my wife gave me an idea. She said, 'Nobody has any money, but they can always scrape up fifteen cents to go to a show. Why don't you cut out the charge accounts and make everyone pay ten cents for

a shave and fifteen cents for a haircut? That's just what I did, and I've taken in enough cash the last two months to keep the wolf from the door."

A Main Street dentist told us that his paying practice has almost vanished, that he had had to take his boy out of medical school and didn't know whether he would ever be able to send him back. "There isn't any question about it," an official of the Retail Merchants' Association said: "government money—WPA Relief, Unemployment Compensation, CCC, and the rest—is keeping most of our merchants out of the bankruptcy courts to-day. Last week (this was in July) WPA laid off a lot of men, and all the merchants complained immediately that their sales dropped off."

Indeed, the main spigot of cash in New Castle is no longer private payrolls, but government money. At the rate of expenditures for the first eight months of this year, the Federal and State governments were pouring \$3,246,000 yearly into town. On September 1, 1939, 28 per cent of New Castle's population,* listed as 3,146 cases, were drawing State relief; 8 per cent, 952 cases, unemployment compensation; another 8 per cent, 900 cases, on WPA rolls; and still another 8 per cent, 864 cases, had applied for State relief and were waiting to be accepted. Fifty-two per cent of New Castle is dependent upon government aid for subsistence, or on the verge of it. Another 12 per cent, 1,338 cases, consisting in the main of recently displaced tinplate workers who were high wage earners, are registered at the State Employment Office as unemployed. Before being eligible for relief a worker must prove himself a pauper, and these workers will eventually join the relief rolls when their savings are exhausted.

"Let your Castle and my Castle be New Castle!" With this slogan officers of the Pennsylvania Power Company, subsidiary of the Commonwealth & Southern utility empire, appealed to the workers, business men, and professional people to pull New Castle out of the mire. Thus the Greater New Castle Association was born last winter. For political reasons—certainly not for economic ones—the utility company built a three and one-half million dollar power plant in town, completed this year. The utility company officers frankly admitted that their interest in the Association was to bring payrolls and jobs to town to offset their large losses of industrial and home power customers and to protect their new investment; and they were quick to emphasize that the welfare of the townsfolk coincided with the utility company's interests. Everyone, no matter what his station in life, was invited to join the Association, which raised thirty thousand dollars and hired an executive director and economic experts within a few weeks.

The Association's first circular explained:

"* * * We lost between 1920 and 1939 eleven industries, employing 5,340 workers; we lost through decline in operations 700 workers, or a total of 6,040. We gained in new industries ten. * * * These placed 950 back on employment payrolls, and the expansion of existing industries * * * added 920 more, so we have gained 1,870 employees, but our net loss is 4,170 employees. * * *

"* * * the payroll loss due to industrial decline is conservatively estimated at \$5,000,000 or 28½ percent. * * * What we need is jobs at supportable wages. * * *

But before the Association could bring any new jobs to New Castle it had to obligate itself to pay one per cent of the \$250,000 annual payroll of the pants company that threatened to leave town and throw four hundred workers out of work. This subsidy saved the four hundred jobs, for the moment, and in hailing its victory the Association announced hopes of "increasing (New Castle's) payroll in 1939" by a quarter of a million dollars. Then a bombshell burst. In mid-July U. S. Steel closed the Shenango tinplate works, its sole remaining New Castle operation. Three thousand workers were thrown on the streets. A yearly payroll of five million dollars was lost. New Castle's loss in private employment since 1920 climbed to 7,170, and its annual payroll for the same period fell another five million to seven and one-half million dollars, a fifty-seven per cent drop. Technology dealt the town a third and, this time devastating blow.

Private industry that once employed 11,259 workers now takes care of only 4,071, a drop of sixty-four per cent. Just as the Shenango works closed, the 76th Congress hurt New Castle by cutting WPA wages five dollars a month and reducing WPA jobs from 1,900 in May to 900 in September. Certainly the Association's goal to increase the industrial payroll in 1939 by one-twentieth of the loss of the Shenango works payroll demonstrates its helplessness to cope with the combination of forces that have wrecked the economic life of the town.

*1930 census 48,674; present population not estimated any higher.

V

Unable to help itself, forgotten by private industry, fed meager relief by the State government, ignored by the Roosevelt Administration, and abused by the 76th Congress, New Castle has been revived by World War II. Its revival, however, is partial and temporary. On October 2, 1939, the huge Shenango tinplate works swung open its doors and 2,500 workers rushed in, eager to get back to work. The war-born prosperity is bringing joy into twenty-five hundred homes; eventually there will be another five hundred when the full contingent of Shenango workers returns. But the hopes of four thousand other New Castle families have not yet turned into joy, nor are they likely to. Although much of the town's retail business will be aided, and the potteries, the bronze plant, and other firms will pick up, the war boom will still leave at least one-third of New Castle's population dependent upon government aid.

Furthermore, Shenango's reopening is to be brief. "This is the last lap for the hand-mills," an official of U. S. Steel told us. Strip mills, on the average, produce tinplate fifteen dollars a ton lower than the hand-mills. Under ordinary conditions the capacity of the strip mills is more than enough to meet demands, and if the extraordinary demands are sustained, strip capacity will be increased instead of high-cost obsolete mills being operated indefinitely. In either case, Shenango will be closed as quickly as it has been reopened, and for the last time. Ghost town is New Castle's destiny.

A similar fate awaits more than a score of other steel towns. Technologically displaced workers who have been idle for almost two years—1,500 in Yorkville, Ohio; 1,100 in Elwood, Indiana; 1,000 in Cambridge, Ohio; and thousands more elsewhere—are breathlessly awaiting an announcement that their abandoned mills will reopen. The announcement may come, but the odds are that the war boom will leave these ghost towns untouched. Obsolete mills in a dozen more steel towns—employing 900 in Apollo, Pennsylvania; 1,000 in Follansbee, West Virginia; 2,500 in Newport, Kentucky; and thousands more elsewhere—have taken a new lease on life; their workers new hopes and aspirations. When the war boom collapses these mills will fold up with a terrific crash. And the post-war depression will shake the foundations of another score of steel towns, like Farrell and Vandergrift, Pennsylvania, each employing twenty-five hundred workers, and Massillon, Ohio, with three thousand steel workers, to such an extent that their only destiny can be that of New Castle. Technology takes its toll not only of workers, but of entire mills and complete towns.

The new steel technology means more than a slow elimination of workers; it is wholesale displacement. A hand-mill is a hot, noisy place, crowded with old-style equipment with squads of workers waiting about while others relieve them for short periods at the furnaces. In one such mill of this character the "iron" is handled more than fifty times by tongs and hands before the process is finished.

In a modern strip mill all this vanishes. The place is cool and spacious. A few workers, some scattered about in over-head control booths pushing buttons, handle the "iron" in one operation. Here a huge slab as big as a mattress but weighing several thousand pounds is automatically released from a furnace, rolled into a coil a thousand feet long like a thread on a spool, placed on a conveyor and put through more continuous operations until it is cut into sheets for your automobiles or plates (later tinned) for your canned soup. All the horde of men who once were employed in the making of steel are swept away, leaving a few watchful men guarding controls. And all those swept away are piled up in the scattered steel towns, wondering what next.

Certainly the war boom is no answer to technological unemployment. The unsound social and economic structure of the steel towns remains unchanged. Absentee overlords continue free to legislate their economic future, and that of other basic industry towns, without any responsibility for the social and political effects of such legislation. Throughout the nation there are scores of industrial towns dominated by one industry or large corporation that are now prosperous, but doomed to economic destruction by the same forces that have raised the economic life of New Castle. These forces like mass unemployment and the country's other more obvious economic ills, will be more ugly and difficult of solution when the boom and its allaying effects are over. In addition, the maladjustments in our economic machinery, as during World War I, are being aggravated by the war-boom recovery, after which our task of domestic reconstruction will be the same as in March, 1933, only ten times greater.

Gradually the American people as a whole will recover from the suddenness, enormity, and intellectual shock of World War II, and the immediate prospects of personal economic gain from the prosperity it has provoked, to realize with

Carl Sandburg, poet and biographer of Abraham Lincoln, "that in this hour mankind's greatest need is a common agreement on the causes and conditions that have produced idlers at the top and bottom of society." And that such an agreement will

"* * * have to consider the vast mass of unspeakable, inarticulate, woe-begone human tragedy gathered under the head of that hideous but accurate phrase from the science of economics, 'the technologically disemployed'—the people whose jobs have been abolished and destroyed by machines and new industrial processes and transitions. * * *"

The purpose of the agreement will be to provide the basis for an "arrangement by which the idle rich and the idle poor could make a two-power pact to take care of each other" in a way that no war boom can possibly do.

EXHIBIT No. 2479

[Submitted by the Steel Workers' Organizing Committee]

DISPLACEMENT OF MEN BY AUTOMATIC STRIP MILLS

Summary

Already Displaced (Names of Plants Attached).....	38,470 workers
To Be Displaced In Integrated Companies (Names of Plants Held in Confidence).....	22,950 workers
To Be Displaced in Small Independent Companies (Names of Companies Held in Confidence).....	23,350 workers
Total Displacement By Automatic Strip Mills.....	84,770 workers

EXPLANATION

Of the 84,770 hand mill workers adversely affected by the automatic strip mills, 88,470 have already been displaced. The mills in which they have been displaced are attached hereto, indicating the year in which the displacement took place. In this compilation an effort has been made to place each abandoned mill in that year in which it last operated substantially. This rule could not be followed in all cases; and some are listed in the year in which they were abandoned, which is usually later than the year last operated.

Of necessity the number of hand mill workers displaced in each abandoned mill is estimated, and most estimates are conservative. The number of workers affected in mills of equal size but abandoned in different years is not strictly comparable because of the difference in maximum weekly hours prevailing in different years. Hand mill workers displaced as a result of the installation of semi-automatic reversing mills are also included in this list. This list is not complete, but includes the major hand mills abandoned during the 1930's as a result of the introduction of the automatic strip mills.

EXHIBIT No. 2481-A

[Submitted by the Steel Workers' Organizing Committee]

A SUMMARY OF "EMPLOYMENT AND PRODUCTIVITY IN A SHEET STEEL MILL" BY
DR. JENNETTE R. GRUENER

(The complete 85-page study was submitted to the Temporary National Economic
Committee)

This study deals with labor displacement from 1919 to 1933 in a single eastern sheet steel mill. Although certain desired material is lacking, the author establishes a number of significant points.

This sheet mill employed an average of 754 men and produced 64,449 tons of sheets in 1919. In 1929 it employed 372 men, but produced 84,756 tons of sheets. In other words, total production was 32% greater, but the working force 51% smaller.

From 1919 to 1925 both production and the size of the force fluctuated much in a similar manner; but from 1926 on the two took different trends—employ-

CONCENTRATION OF ECONOMIC POWER

ment decreasing in spite of sustained or increased production. The source of this difference is found in the company's program of increasing productivity through improved technology. The concern embarked upon a comprehensive program of this nature in 1924 and continued it until 1928, although it was practically completed by 1927. The following table shows the results:

Year	Output Mo. Avg. (tons)	Man-Hours Worked (Monthly Average)	Total Labor Costs (Monthly Average)	Avg. No. Men Employed
1925	6,212	154,624	\$100,657	684
1926	7,325	162,118	107,848	784
1927	5,453	102,992	72,597	506
1928	6,002	77,239	59,767	354
1929	7,053	81,135	65,841	372

Production in 1928 was about 3.4% less than in 1925. Man-hours per month declined 50% and the working force declined 48%. In 1929 production was about 3.7% less than in 1926. Man-hours declined 50% and the working force dropped 52.5%.

To the workers the program meant the following: In 1929 they produced 13.5% more per month than in 1925, for which they received a 45.6% decreased working force, a decrease of 47.5% in the man-hours they worked, and an overall wage decrease amounting to \$34,816, or 34.6%.

The author of the study made an estimate of the technological displacement of workers based on a comparison of man-hours and production for 1925 and 1929. The resultant figure was about 83,167 technologically displaced man-hours per month. Allowing 48 hours per week and 208 hours per month for each man, we find that in 1929 about 400 men who would otherwise have been employed were out of jobs as a result of technological improvements in this mill alone.

EXHIBIT No. 2484

[Submitted by the Steel Workers Organizing Committee]

Explanation of material submitted in the following charts:

Exhibit 2485—Man-Hours Per Ton of Ingots Produced

Exhibit 2486—Wages Per Ton of Ingots Produced

Exhibit 2487—Relation of Production to Payrolls (at 72% to 76% of Ingot Capacity)

Exhibit 2488—Relation of Production to Employment (at 72% to 76% of Ingot Capacity)

Source of material:

American Iron & Steel Institute, New York City, Statistical Sheets 1 and 2 which are distributed to companies in the steel industry which supply data to the American Iron & Steel Institute.

Periods of comparison:

Three representative months are used for the basis of comparison. They are August, 1936, September, 1937, and September, 1939.

Actual ingot production in each of these three months was virtually the same, varying not more than 1% to 2% either way. The rate of operations in these months varied from 72% to 76% of ingot capacity. This rate of operations is truly representative of profitable operations in the steel industry. 90% of capacity or more is not representative of steel operations

because in the past seven years in only three months has the industry operated at 90% of capacity or better.

Employees covered:

The total monthly hours worked, average hourly earnings, and total monthly wages are for employees who are paid on an hourly, piece work, or tonnage basis.

The figures illustrated in these charts are not adjusted for the entire steel industry. These figures cover more than 90% of the industry and are used for the purpose of showing relationships. When adjusted for the entire industry, the relationships between production, employment, and payrolls do not change because the adjustment of all factors would be made on the same basis.

EXHIBIT 2485—MAN-HOURS PER TON OF INGOTS PRODUCED

This chart shows the changing relationship of total monthly hours worked to ingot production.

Man-hours per ton of ingots produced was computed by dividing total monthly hours worked by hourly, piece work, and tonnage employees by the monthly open hearth and Bessemer steel ingots produced. The total monthly hours worked cover all operations in the steel industry. These hours are related to ingot production because the latter is the accepted measurement of production.

In August, 1936, the man-hours per ton of ingots produced was 18.7. In September, 1937, this declined to 18.5; and by September, 1939, it had declined to 14.7. In the following month, October, 1939, it had declined to 14.5. It returned to 14.7 in November, 1939, and to 14.9 in December, 1939.

A 21.4% decline in man-hours took place from August, 1936, to September, 1939, or a drop from 18.7 man-hours to 14.7.

EXHIBIT 2486—WAGES PER TON OF INGOTS PRODUCED

This chart shows the relationship between monthly wages and monthly ingot production.

Wages per ton of ingots produced was computed by dividing the total monthly wages received by hourly, piece work, and tonnage employees by the monthly open hearth and Bessemer steel ingots produced. The total monthly wages paid are for all operations in the steel industry.

The wages paid per ton of ingots produced in August, 1936, was \$12.50. In September, 1937, it had risen to \$15.61, primarily as a result of an increase in average hourly earnings. By September, 1939, wages per ton of ingots produced had returned to \$12.51 a ton. In October, 1939, wages per ton of ingots declined to \$12.32. In November, 1939, they rose to \$12.52 and in December, 1939, to \$12.77.

Despite an increase in average hourly earnings from August, 1936, to September, 1939, wages per ton of ingots produced in these two months were virtually the same.

EXHIBIT 2487—RELATION OF PRODUCTION TO PAYROLLS

In this chart payrolls are set forth in two terms: average hourly earnings, and total monthly wages.

From August, 1936, to September, 1937, average hourly earnings increased from 66.8 cents to 84.3 cents per hour, or 26%. From September, 1937, to September, 1939, average hourly earnings increased from 84.3 cents to 85.1 cents per hour, or 1%. The increase in average hourly earnings from August, 1936, to September, 1939, was 27.3%.

Total monthly wages increased 27.7% from August, 1936, to September, 1937, or a little more than \$14,500,000 (From \$52,278,846 to \$66,800,712). By September, 1939, total monthly wages had declined to \$52,921,352.

The increase in total monthly wages from August, 1936, to September, 1939, was 1.2%, and the increase in production from August, 1936, to September, 1939, was 1%.

EXHIBIT 2488—RELATION OF PRODUCTION TO EMPLOYMENT

This chart shows the relation of production to employment in terms of wage earners and man-hours.

As a result of the reduction in maximum hours of work per week from 48 to 40 in 1937, the number of wage earners rose by 58,690 from August, 1936, to September, 1937, or 13%. In September, 1939, the number of wage earners was 415,171. Compared to September, 1937, when maximum weekly hours were the

CONCENTRATION OF ECONOMIC POWER

17345

same, this represents a drop of 88,472 wage earners, or 17.5%. Compared to August, 1936, when maximum weekly hours were eight per week higher, this represents a drop of 29,782 workers, or about 7%.

Total man-hours worked per month rose from 78,208,172 in August, 1936, to 79,230,977 in September, 1937, an increase of 1%. By September, 1939, the man-hours worked per month declined by 17,059,554 from September, 1937, or a decrease of 21.5%. Although production in September, 1939, was 1% greater than in August, 1936, the total man-hours worked had decreased 20.4%.

TECHNOLOGY AND EMPLOYMENT

Hearings before the Temporary National Economic Committee

By H. DEWEY ANDERSON

DESCRIPTION OF TERMS

The following descriptions have been compiled to present the most commonly used and accepted meanings of certain terms appearing frequently in the literature and statistics dealing with employment and production. Unfortunately, there is no universal agreement in the use of these terms nor in the methods of compiling the statistics. In other words, in individual studies and particular statistical series the definitions may vary from those given here because of the special nature of the problem under consideration or the limitations of the statistics. The principal limitation of the statistical measures described here, as well as some of the most frequent misuses of the data, are also indicated.

Gainfully employed.—The "gainfully employed" or "gainful workers" is a term used in the decennial census reports on occupations. "The term 'gainful workers' [in census usage], includes all persons 10 years old and over who usually follow a gainful occupation, even though they may not have been actually employed at the time the census was taken. It does not include women doing housework in their own homes, without wages, and having no other employment, nor children working at home, merely on general household work, on chores, or at odd times on other work."¹

It is not a count of the number of persons employed nor of the number of jobs available. The number of gainful workers is a much more stable series than the number employed and responds much more slowly than employment to changes in the volume of production. In fact, it is conceivable that during an extended depression the number of gainful workers would increase. For example, married women may seek jobs in depression to supplement the family income, whereas in more prosperous times they would remain at home and would not be counted as gainful workers. Extension of child labor laws, on the other hand, automatically decreases the number of gainful workers, irrespective of the trend in production.

Changes in the methods of compilation and in the census definition of "gainful workers" limit the comparability of the census figures over a long period. Beginning with the census of 1870, the occupation inquiry applied to all persons in the population. The possible discrepancies in the total number of gainful workers in various censuses since then, caused by such factors as changes in instructions to enumerators and changes in the census date, are evaluated in the census. Comparisons of shifts of workers among occupations and among industries are subject to even greater limitations than changes in the totals.²

This term has been discussed at length because throughout the current literature on technological change there is a tendency to use the number of "gainful workers" and "gainfully employed" to indicate the number of jobs or the number of persons at work. The terms are not synonymous, and in periods of depression the difference between the number of gainful workers and those actually at work is very important. Unfortunately, comprehensive figures on the total number of people actually at work cover only the period since 1929, and even these figures are only approximations. For many industrial subdivisions the estimates are less reliable than the over-all figures. Consequently, historical comparisons are dependent on the figures in the occupational census. The point to be stressed is that although these are the best figures available, they cannot be used to measure the relationship between technology and employment except in a very rough way in view of the numerous limitations which have been pointed out.

Employed person.—An "employed person" is one who is currently engaged in a gainful occupation, i. e., actively engaged for a return in cash or kind. This includes both those working for others and the self-employed. All farm family labor (employables in the farm family who work on the farm without receiving a stated wage) and farm operators are counted as employed persons. Women doing housework in their own homes, without wages, and having no other employment, are not counted as employed. Persons enrolled in the Civilian Conservation Corps or engaged on W. P. A. and N. Y. A. work projects or C. W. A. and

¹ Fifteenth Census of the United States: 1930, "Population", Vol. V, p. 59.

² For discussion of these changes, see *ibid.*, pp. 4-5 and 38-39.

F. E. R. A. work programs are not counted as employed. Persons employed on Public Works Administration projects, on the other hand, are counted as employed. Most P. W. A. projects involve construction and are carried on largely under contract and are thus closely related to private activity.

Most employment indexes reflect the number of persons who worked during the week ending nearest the middle of the month represented by the index. These indexes include part-time as well as full-time workers; consequently, the estimated number of persons employed also includes both full time and part-time workers.

Unemployed person.—In current estimates the number of "unemployed" represents the difference between the number of "gainful workers" and the number employed. An "unemployed person" may thus be defined as one of working age who is able and willing to work and who normally would be employed, but who is not currently engaged in a gainful occupation.

Separations.—Separation refers to the termination of employment of an individual, whether voluntary or involuntary, at either the instance of the employer or the employee.

Wage earners and salaried employees.—The distinction between salaried officers and employees, on the one hand, and wage earners, on the other, depends primarily on the character of the work done. The first group includes, in general, supervisory and office employees, and the second group, manual workers. The Census of Manufactures makes the following distinction:

"In the salaried group are included principal officers of corporations; managers, superintendents, and other responsible administrative employees; foremen and overseers who devote all or the greater part of their time to supervisory duties; and clerks, stenographers, bookkeepers, and other clerical employees on salary. Wage earners are defined as skilled and unskilled workers of all classes, including piece-workers employed at the plant, and foremen and overseers in minor positions who perform work similar to that done by the employees under their supervision."²

The statistics for these two groups are collected on a somewhat different basis. The number of salaried employees is reported to the Census of Manufactures for December 14, or the nearest representative day. As a rule, there is little variation from month to month in the number of employees of this class, and this number is treated as equivalent to the average for the year.

For wage earners, the number shown by the payroll for the week which included the 15th day of each month, or for some other representative week, is reported. The *average number of wage earners employed* is calculated by dividing the sum of the numbers reported for each month by 12. The average number of wage earners in any industry, thus calculated, is necessarily somewhat in excess of the number that would be required to perform the work if all were employed continuously during the year. The reason is that the payroll for any week is likely to contain the names of employees who have been temporarily laid off and of persons whose services had terminated before the close of the week covered by the payroll. Also, if a manufacturer operated his plant only part of a month, he would select an active week as a representative week and would report the total number of wage earners whose names were on the rolls for that week. In other words, these figures indicate outright reductions in the number of wage earners, but they do not reflect part-time employment.

Indexes of factory employment and payrolls.—The Census data on employment and payrolls are collected at intervals of two or more years, and to supplement these data various indexes of employment and payrolls have been compiled to indicate current trends. The most comprehensive figures of this type are the indexes of factory employment and payrolls computed monthly by the U. S. Bureau of Labor Statistics. These indexes are based on monthly reports of a carefully selected sample of manufacturers who report the number of wage earners and their total wages for the week ending nearest the 15th of the month. The number of wage earners reported each month and their weekly wages are expressed as percentages of the average number on the payrolls and the average weekly wages in the years 1923, 1924, and 1925.

Indexes which are based on samples may tend to deviate from the true trend for an industry over an extended period. To overcome this tendency, the Bureau of Labor Statistics has adjusted most of its indexes to factory employment and payrolls to conform with the averages shown in the biennial Census of Manufactures. The Bureau of Labor Statistics indexes of factory employment and payrolls thus describe, in percentages, essentially the same class of employees included in the Census figure of average wage earners for the year.

² Fifteenth Census of the United States, "Manufactures: 1929," Vol. II, p. 5.

Man-hours.—The number of man-hours is a measure of employment which takes into consideration the length of time worked. In other words, total man-hours per year reflects not only the number of wage earners employed, but also the number of weeks they worked and the length of the working week.

Production.—Production refers to the volume of commodities and services made available for consumption. A production series measures the changes in the quantity of goods made or services rendered over a specified period of time. Production in agriculture refers to bushels of wheat, gallons of milk, dozens of eggs, bales of cotton, and so forth; in the motor vehicle industry, to the number of cars and parts; in the telephone industry, to the number of local and toll calls; in steam railroads, to the number of freight-ton miles and passenger miles. The complexity of our industrial organization and the variety of products result in numerous statistical difficulties in any attempt to measure the output of a single plant or industry, and the difficulties increase as the industrial area included is extended. Consequently, most measures of production are based on selected products or services which are considered representative and typical. In all comparisons of production with employment and payrolls, it is therefore essential to determine whether all of the series cover the same group of products. In other words, did the employees devote their full time to producing the goods included in the production index?

Productivity.—Measures of productivity relate physical volume of output to the amount of labor expended in producing it. In other words, productivity is the ratio of output of product to input of labor. There are several ways of expressing this ratio, two of the most common being output per wage earner and output per man-hour. The difference between the two is obvious: in one case output for a given period is divided by the number of wage earners employed, while in the other output is divided by total man-hours of employment during the production period.

The trends in output per wage earner and output per man-hour may not be the same. Output per wage earner may decline while output per man-hour increases, if the hours of work have been reduced. For this reason output per wage earner is less reliable than output per man-hour as an indication of the effects of technological change on productivity.

It should also be borne in mind that changes in output per wage earner or per man-hour in an industry arise from causes other than technological change. In coal mining for example, output per man-hour may rise because some of the poorer mines have been closed. On the other hand, it may decrease over a long period because the richer veins have been exhausted and it requires more effort to get the same amount of coal from the thinner veins. For some industries, the quality of the product has been improved, but the improvement in quality is not reflected in the production index. If the improvements require additional man-hours, output per man-hour may appear to be decreasing simply because the production index is too crude to reflect the changes in quality.

Seasonal variation.—Seasonal variation is a term applied to recurrent seasonal movements, such as the recession in midsummer and midwinter and increased activity in spring and autumn, that are frequently apparent in monthly or weekly statistical series. Some series are adjusted for seasonal variation. The Federal Reserve Board indexes of industrial production, for example, are published "Adjusted for Seasonal Variation" and "Without Seasonal Adjustment." The purpose of the adjustment is to eliminate insofar as possible the changes which are due primarily to seasonal factors and to focus attention on variations arising from other causes.

Calendar year.—Calendar year refers to an annual period beginning in January and ending in the following December. Most statistical series relating to employment and production are reported on a calendar-year basis.

Production year.—Production year is a general term used in contrast with calendar year. It is applied in industries in which measures of production are more significant when reported from the normal period of operations rather than for a calendar year which imposes artificial limits and may result in a meaningless statistical series. There are numerous terms used in particular industries to express this idea. For example, in agriculture and in industries processing agricultural products, annual series are compiled for the crop year, harvest year, and growth year. The terminal months for such series are determined by the customary harvesting and marketing periods. Sometimes statistics for the automobile industry are presented for the model year, beginning in September and ending with the following August.

Campaign period.—"Campaign" is a term used in some highly seasonal industries which do not operate continuously throughout the year. In the beet sugar industry, for example, seasonality is caused by the perishability of the beets, which cannot be stored. Hence the factory must operate when new crops of sugar beets are harvested. The period of operation is known as the campaign. Once the campaign has begun, the factory may operate 24 hours a day until the supply of harvested beets is exhausted. In this industry, the campaign period has varied from 15 to over 100 days, averaging about 70 days for the past few years. The campaign in beet sugar often runs into January of the next year; hence, in this industry the "campaign year" is usually defined as the year extending from March 1 to February 28.

National income.—The phrase "national income" has been loosely applied to a variety of concepts and statistical measurements. The estimates of "national income" vary according to the statistical concept or measure selected, and this accounts for a great deal of the misunderstanding and apparent contradictions in discussions of income. In the usage of the U. S. Department of Commerce, in its official estimates of income in the United States, "national income" is an abbreviation for "national income produced."

National income produced is the most inclusive of the concepts used by the Department of Commerce, and is a measure of "the net value of all commodities produced and all services rendered in the country. This total can be described as representing the gross value of all goods and services produced, minus the value of all raw materials and capital equipment consumed in the processes of production. It may also be designated as the value of goods and services consumed plus the value of additions to the national wealth during the year."⁴ This definition must be further qualified to the effect that it covers primarily only efforts whose results appear on the market-place of the economy. In other words, such services as are performed by housewives do not appear on the market, and are therefore not included in the estimate.⁵ This is important to bear in mind in comparisons of income over a long period of time, for the fact that many activities such as baking, sewing, canning, and gardening have to a large extent been transferred from the home to the market-place tends to increase the estimates of national income, without commensurately increasing the quantity of goods and services available for consumption.

The Department of Commerce also publishes estimates of "income paid out," which may be described as "the compensation paid to individuals for personal and capital services rendered."⁶

In any one year the income produced may be larger or smaller than the total income paid out by all business enterprises. When it is larger the difference is called "positive business savings" and represents the proportion of the year's net product retained by business enterprises. When income produced is smaller than income paid out, the difference is labeled "negative business savings" and represents a decrease in the net worth of business enterprises as a result of the current year's operations.

These two measures have been selected for definition because they describe the official income statistics. The National Industrial Conference Board also publishes estimates of national income, using definitions which differ from those given here. Space does not permit a description of the numerous statistical measures of income. It should be emphasized, however, that since there is such a variety of measures loosely referred to as "national income," it is essential to know what each includes before any use is made of the statistics. Otherwise, the conclusions may be misleading.

Purchasing power.—Purchasing power is a measure of the quantity of goods and services a given amount of money will buy. The distinction between purchasing power and income arises because prices fluctuate. A measure of income is converted into a measure of purchasing power by dividing income by an index representing the average prices of goods and services purchased. Various cost-of-living indexes are used to convert income figures into purchasing power series.

⁴ Robert R. Nathan, *Income in the United States, 1929-1937*, U. S. Department of Commerce, p. 3.

⁵ For the items not included in the estimates, see *ibid.*, pp. 6-7.

Nature of Technological Changes.	Other Employment Considerations.
General.	1933 Period.
Switching Systems.	Conclusion.
Transmission of Speech.	
Other Aspects of Technological Changes.	

This statement and exhibits were prepared following the receipt of a letter dated January 24, 1940, from the Temporary National Economic Committee to the American Telephone and Telegraph Company inviting information on technology in the telephone industry. An attachment to that letter defines technology as follows:

"While technology is often used to mean the machine process which increases productivity, it is here meant to describe that noticeable change or combination of changes in the techniques of management, trade, finance, production, processing, and distribution by which the productivity of labor is considerably increased."

This statement accordingly deals with the broad aspect of technology as it may be encountered in the activities of the Bell System with particular reference to employment.

At the outset it may be well to outline briefly the need for and character of technology in the Bell System.

The telephone business is a business based upon scientific discovery and scientific invention. Technological progress in the physical instrumentalities of the business and in management methods has been continuously required to meet the ever-changing actual and potential needs of the nation for telephone service. Without the technological progress which has been achieved, it would have been impossible to provide telephone service of the present scope at any price. Without this technological progress, it would have been impossible to furnish a telephone service which is unequaled anywhere else in the world for scope, speed, accuracy, dependability and low cost.

The record shows that the Bell System has been alert to foresee and anticipate the needs and opportunities for technological progress. But more than that, it also has been the aim and policy to introduce into its plant or practices those new technical developments which are clearly essential to progress, and to do this in such a way as to avoid or minimize any possible adverse effects in the nature of economic waste or human hardship. Broadly speaking, employees affected by improvements in apparatus or operating methods have not been laid off but have been retrained and reassigned. An exception has been the conversion of certain manual central offices to dial operation. Even in these instances, the separations from service consequent upon the conversion have been held to a minimum; and since the early 1930's it has been increasingly the practice to make lump-sum termination payments to those individual employees for whom no work could be found, in order to help them over the interval before they secured new employment if new employment was sought.

The long term effects of technological progress upon the scope, quality and cost of telephone service without exception have been beneficial to all participants in the business—employees, investors, and customers—as well as to society as a whole. By overcoming, one after another, physical limitations upon the possibilities of telephone expansion, technology has increased the aggregate opportunities for employment. Similarly, it has created new investment opportunities and has expanded the demand for capital goods. Technology has made for advances in wages, shorter hours, more highly skilled jobs and many other betterments in working conditions; and these betterments have been realized without the use of "speed-up" systems.

Technology in the Bell System has not benefited one group at the expense of any other group. Labor has received a practically constant proportion of the revenue dollar. While the proportion of the revenue dollar going to capital has tended to decline, investors have received regular reasonable returns (partly out of past earnings in years when current earnings have been insufficient).

In the future, technology in the pursuance of Bell System policy will produce the same type of results as in the past. There is a large potential market for more and more telephone service. The importance of developing this market is recognized. Technology will be a force in this. The resultant growth will increase employment. The need for new capital goods for plant additions and betterments will be substantial and new capital must be attracted to the business.

ORGANIZATION

In directing attention to the more specific aspects of technology in the Bell System it will be helpful to first outline briefly the nature and scope of the organization we are considering.

The Bell System is a closely integrated group of telephone companies associated for the purpose of providing, in conjunction with several thousand independently owned companies, a single, unified telephone service in the United States. There are now close to 21,000,000 telephones in the United States, of which nearly 17,000,000 are in the Bell System.

The American Telephone and Telegraph Company is the parent company, and there are twenty-four principal telephone operating subsidiaries, each functioning within a given territory.

In general, the operating companies provide telephone service and interconnect communities within their own territories. The American Company, through its Long Lines Department, constructs, maintains, and operates inter-state long distance lines and other facilities by which the telephone lines of the operating companies, and of independent connecting companies, are united to provide nationwide and world-wide service, and are linked with telephones on ships at sea.

The American Company also performs certain functions which can most effectively and economically be performed centrally and which are essential to the continuous improvement of telephone service and its provision at the lowest cost to the public. Its headquarters staff furnishes the operating companies with engineering assistance and operating advice, as well as assistance and advice in legal, accounting, financial and other matters. Also it conducts for the System extensive research and development work in the Bell Telephone Laboratories. A subsidiary, the Western Electric Company, serves as the manufacturer and purchasing agent for the System.

GROWTH

Before embarking on a consideration of the kaleidoscopic changes which have taken place in recent years in the art of communication, it will be helpful to retrace the road traveled by this comparatively young industry.

Prior to the invention of the telephone in 1875, communication other than by direct conversation was for the most part confined to the interchange of written messages by the mails and the telegraph. The telephone made it possible for the first time to transmit the spoken word and thus opened up the whole range of present-day voice communication which now knows no barriers of time or distance—world-wide telephony, radio broadcasting and all the related fields.

That these possibilities were early recognized is shown by the following excerpt from the Certificate of Incorporation of the American Telephone and Telegraph Company, dated February 28, 1885.

"And it is further declared and certified that the general route of the lines of this association, in addition to those hereinbefore described or designated, will connect one or more points in each and every city, town or place in the State of New York with one or more points in each and every other city, town or place in said State, and in each and every other of the United States, and in Canada and Mexico, and each and every of said cities, towns and places is to be connected with each and every other city, town or place in said States and Countries, and also by cable and other appropriate means with the rest of the known world as may hereafter become necessary or desirable in conducting the business of this association."

This romantic picture was drawn when there was only the most elementary knowledge of the art. The telephone had grown out of science and the founders of the industry foresaw the unlimited possibilities through further application of science, research and management. Today's telephone service affirms the completeness of this early vision.

The history of the Bell System is the story of an organization serving the every-changing needs of society in a field where new frontiers of knowledge in the arts and sciences are constantly opening up.

Some of the more significant aspects of the expansion of the business are illustrated in the graphs opposite.¹

These graphs suggest the extent to which a single invention, continuously developed, has contributed to economic and social progress. It has made possible a service which not only of itself has aided progress, but has provided increased opportunities for labor and for capital. When it is realized that the graphs cover only the Bell Operating Companies and not the independent operating companies, the manufacturing companies or the telephone operators employed in connection with private branch exchange and other services on the customer's premises, the magnitude of this contribution becomes even more striking. Furthermore, the very trends give strong hope of continued progress.

To facilitate discussion, the graphs and references herein cover the American Company and its principal telephone subsidiaries, which comprise nearly 90 per cent. of the employees and about 97 per cent. of the investment of the entire Bell organization.

NATURE OF TECHNOLOGICAL CHANGES

To consider the general matter of technology and the productivity of labor within the System in relation to employment, it is first necessary to review briefly some of the basic factors which control the trend of technological development.

General.—To the layman, the operations of the telephone business may appear simple, seeing, as he does, only such things as the telephone instrument and poles and wires, but to one who has been able to look behind the scenes the complexity and evolutionary nature of the business become immediately apparent. In no period has the business ever remained static—and this is so today—controlled as it is by the changing and expanding needs of society and the continuous advances in the fund of human knowledge. All the engineering arts and their underlying sciences are basic to its progress. All the complex facilities for the transmission of speech and signaling and for the control or switching of channels of communication have had to be devised. New materials, alloys, and compounds have had to be invented or developed. Mathematics, physics and chemistry all underlie this work. Biology and botany enter into the consideration of textiles and timber products used in telephone plant. Physiology and psychology enter into many aspects of the action of the vocal and auditory organs of the human body, so intimately associated with the use of the telephone.

Technological advances are therefore basic. Equally essential to the sound conduct of the business are advances in administration, operation, finance and human relationships so necessary to the rendering of a public service.

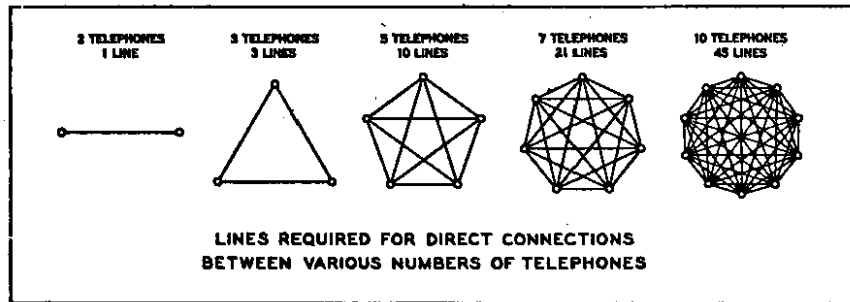

It will be clear from later discussion that the very nature of the business—growth, constantly changing requirements, advances in knowledge of the art, etc.—has brought about the evolutionary change in instrumentalities, practices and procedures. Similarly it will be clear that each change is weighed carefully in relation to its possible effect on employment and any other considerations that may affect the men and women of the organization.

With this background, a brief discussion of some of the technological changes in connection with the telephone business and the reasons leading thereto is appropriate. No attempt will be made to consider separately the research and development, operation or manufacturing aspects. Many phases of operations might be chosen but the two most basic will indicate the trend. One is the development of switching systems for interconnecting individual telephone customers with one another; the other, the instrumentalities for the transmission of conversation.

Switching Systems.—The earliest problem of interconnecting telephones grew out of the multiplicity of lines required for direct connections between subscribers. With only two subscribers to be interconnected, simply one line would be required; for direct connections for three subscribers, three lines; for five sub-

¹ Entered as "Exhibit No. 2569," see supra, p. 16040.

scribers, 10 lines; for 10 subscribers, 45 lines; for 100 subscribers, 4,950 lines; 1,000 subscribers, nearly one-half million lines; and so on to astronomical numbers. The principle is indicated diagrammatically below.

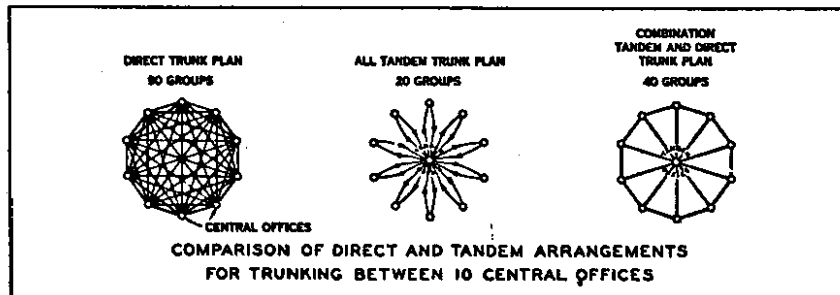

It was clear that this complexity had to be met by means of a "switchboard" where all subscribers' lines terminated and where any two could be linked together by an operator.

The only apparatus available at that time for this purpose was that employed in telegraph, messenger, and burglar alarm systems. While some of this, such as wire, insulators, batteries, annunciators, etc., was found useful, the requirements of telephone service called for signaling and switching equipment different from that employed in any other branch of the electrical industry. This made it necessary to develop an entirely new switching art.

When the number of calls became too great for one operator to handle, the subscribers' terminals had to be duplicated or multiplied one or more times so that each of the operators could reach all terminals for completing calls. This requirement caused a large increase in the central office in the amount of equipment for each subscriber and greatly increased the complexity of the equipment and operating work.

As the number of subscribers in a community became too great for a single central office, a second office just like the first had to be installed and means provided for connecting the two offices. This necessitated circuits called "trunks" between the two offices. Later on an additional switchboard of a new type called a "B" switchboard, for terminating these trunks in each office, was required. This meant extra operators in each office for completing the trunk calls. Each such call thus required the services of two operators.

Now, as the number of central offices grew, more interconnecting problems arose similar to the original one of connecting individual subscribers. For example, to connect two central offices, two trunks or groups are required, one in each direction; to connect four offices, 12 groups are required; for 10 offices, 90 groups; for 100 offices, 9,900 groups, etc. In order to reduce the number of trunks another new type of switchboard, known as a "tandem" board, had to be developed. How such a board made possible fewer trunks is illustrated below.

As the business grew, the increase of trunking and the introduction of tandem switching further complicated the operating work. The operators had to know or be able to ascertain quickly the route to a large and increasing number of called offices. With the introduction of the third operator (tandem operator) on some calls, the chances for delays and errors materially increased.

It is a long step from the early switchboards to the modern ones. As time went on wholly manual service became increasingly inadequate and more and more mechanical aids were necessary in order to give speedy, accurate and effective service. For example, at the start it was necessary for the subscriber to signal the operator by turning a crank on a magneto generator at his station, which action tripped a "drop" in front of the operator which she had to restore by hand after answering the call. Later, a lamp was substituted which lighted when the subscriber lifted his receiver to make a call and was extinguished when he hung up his receiver. Many other arrangements of a machine character became necessary and desirable. Among these were automatic ringing of the subscriber's bell and many forms of signaling. Thus, requirements of the service called for more and more automatic operation, although very few of these changes were visible to the public.

It early became evident that the future demand for service would be such that switching systems and operating methods would continue to be more and more complex and it was clear that manual operation, even with such automatic features as could reasonably be introduced, would be less and less suitable for handling the anticipated volumes of traffic, to say nothing of permitting improvements in quality of service. As an indication of this problem, one has but to consider the situation in one of the large cities where hundreds of thousands of telephones are served from many central offices. Each subscriber in this network—and it must be borne in mind that there are many types of service: Business, residence, coin box, measured, flat rate, etc.—must be able to reach promptly every other subscriber and every other class of service. Furthermore, the necessity for reaching the extensive suburban areas as well as the vast number of cities, towns and rural communities throughout the country requires the handling of thousands of suburban and long distance messages daily, each of which must be recorded, supervised and timed. One can readily appreciate the growing complexity of the operating work to meet this situation and the difficulty of maintaining an accurate and efficient service through the medium of manual operating methods alone. From such practical realities as these, it was certain that manual switchboards, even with such automatic features as could be provided to assist the operator, could not continue indefinitely to meet adequately the local operating problems of the larger cities.

It inevitably followed that switching equipment to complete certain types of connections entirely by mechanical means would ultimately be required. After exhaustive investigations and experiments, an automatic switchboard which met the exacting service conditions was developed and introduced for general use in the early 1920's. Like the manual boards, these automatic boards continue to undergo change and improvement to better adapt them for the ever-expanding needs of the business. As an indication of this continuing evolution, a new dial switchboard known as the "cross-bar" was introduced in 1938.

Transmission of Speech.—No matter how speedy and accurate the connection, service is unsatisfactory if the maze of wires, switchboards and other apparatus does not provide connections over which customers can talk and hear easily and without repetition or interruption. Thus, in addition to the problems of switching, there are the problems of putting together and maintaining the various parts which go to make up the intricate and extensive telephone plant so that every one of the millions of connections established each day will permit a satisfactory talk, no matter what the distance.

In the early days the transmitters and receivers were, of course, relatively crude and inefficient. The lines were noisy and were affected by all manner of electrical disturbances. Connections were limited to distances of a few miles. To permit the service to expand, ways had to be found to improve transmission. Early research in this field led to the development of such things as the metallic circuit, hard-drawn copper wire, and to improvements in the subscribers' instruments themselves.

With the continued increase in the number of subscribers, especially in the larger cities, the amount of wire strung along the pole lines and across housetops began to be so great as to constitute a serious problem. For example, some of the open wire routes along the principal streets of the cities employed poles ranging up to 90 feet in height which carried over 20 crossarms. These cumbersome structures with the mass of wires carried across highways and rooftops where vulnerable to

fires and sleet storms. This is illustrated by the picture which shows the pole line and wire arrangements on lower Broadway at John Street, New York City, in 1890.

Under these conditions, and looking ahead, more reliable and compact forms of line construction became necessary. This led to the development of cables. The earliest ones were far from satisfactory. As the single wire grounded method of transmission was employed, noise and crosstalk, that is, overhearing from one circuit to another, were troublesome. Also, the existing types of insulation resulted in the strength of the voice currents being reduced rapidly as they proceeded along the circuit. These conditions limited the length of cable to a few thousand feet and necessitated development of more efficient cables. This led to the use of paper insulation on the wires, which reduced the transmission losses, and to the provision of twisted pairs in the cables for metallic transmission. With more satisfactory cable circuits, the process of replacing open wires in the larger cities proceeded rapidly. Longer and longer lengths of cable required still more efficient transmitters and receivers; this in turn necessitated continued development to bring about improvements in station apparatus.

Along with the rapid expansion within cities, there was a rising demand for service between cities. The first line between Boston and New York was completed in 1894 and there followed many extensions to more distant parts of the country. These lines, of the open wire type, were subject to the same hazards of sleet and fire as the city plant and soon many had to be placed in cable. Due to the large transmission losses these first intercity cables were limited to tens rather than hundreds of miles. In the early 1900's, after intensive development work, a new means of improving the transmission in cables became available, known as the loading coil. This is an inductance which, when inserted in the cable pairs at periodic intervals, greatly reduces the transmission loss. With this new development, it was possible by 1913 to place the toll circuits in cable along the eastern seaboard from Boston to Washington, D. C.

Even with large gauge conductors equipped with the best loading coils available, inter-city cables could not be extended as far as desired. Furthermore, even with the open wire plant, Denver was about the farthest point with which conversations could be successfully carried on from New York City. To overcome these limitations, work was begun on the development of a telephone repeater, that is, an amplifier, that could be inserted at intervals along the route to overcome transmission losses. A repeater employing a vacuum tube was developed and applied to the New York-San Francisco route in 1914.

These and other developments made it possible to meet the rapidly growing demands for long distance service, using modern-day inter-city cables which provide within a single sheath several hundred telephone circuits and many telegraph and broadcasting network circuits. Looking ahead, it became evident that still other developments were necessary and efforts were directed to finding ways and means of superposing a number of speech channels on one or two pairs of wires. This resulted in the development of telephone carrier, one present-day example of which is the cable carrier system, which provides 12 telephone circuits on two pairs of wires by the use of special terminal equipment and intermediate amplifiers at many points along the line. Intensive research continues and still other forms of carrier employing copper tubing are in the offing.

It is only by means of many technological improvements such as those mentioned above that it has been possible to provide the satisfactory quality of transmission which has been so essential to extending the scope of the business.

These examples of technological changes arising from many sources, some even wholly outside the industry, could be multiplied many times. They are presented here simply to illustrate a fundamental characteristic of the business, namely, that one upon another, technological advances are essential to its very life. And it is clear that progress will only be through this process.

Other Aspects of Technological Changes.—The beneficial long-term effects of technical progress are present in all phases of operations. Reference already has been made to the relation of technology to growth, and to the continual improvements in speed, accuracy and dependability of service.

The very nature of the telephone business (speedy, accurate inter-connection of the constantly expanding millions of telephones throughout the nation, any one with any other—no limitation as to distance or time) necessitates more and more intricate and complex physical instrumentalities. In this, technological advances are essential to keep costs down. While it might be interesting, yet it would be futile, to speculate as to what the cost of present-day service might be under the state of the art say thirty, twenty, or, in some respects, even ten years ago, for the simple reason that service of the present day scope and quality could

not be provided in the light of the art of other days. No one questions that technology has held costs down. It would be impossible to measure the degree. Costs under an outmoded art are themselves outmoded.

The increase in Bell System plant investment which has accompanied technical progress is depicted on the graph opposite page 4 and indicates the magnitude of the demand for new capital investment which growth has entailed. But the demand for new capital goods is not limited to requirements for growth. Capital goods already embodied in physical plant wear out or become outmoded and must be replaced. Therefore, in its effect upon demand for new investment funds for growth and for new capital goods, technological progress in the telephone business has greatly increased the needs.

Finally, what has been the effect of technology upon the human element in the telephone business—the opportunities, wages, and general welfare of men and women? All of this is of vital concern to Bell System management; and since the Committee has indicated a special interest in the subject, a somewhat extended treatment of it appears in the following.

TECHNOLOGY AND EMPLOYMENT

The net result of technological development in the Bell System over the years is—

To create and enlarge opportunity for employment.

To increase the productivity of labor.

To make possible constantly higher wages, shorter hours, and better working conditions.

Enlarged Opportunity for Employment.—Whether or not, as is sometimes said, mechanization and other technological changes reduce opportunities for employment in some industries, such changes in the telephone industry increase employment in the long run. Technological advance, of course, often reduces the labor content of individual telephone operations. To attach undue importance to this would be to overlook the more fundamental consideration that such development overcomes the barriers limiting expansion and thereby opens up new and greater opportunities for employment.

This result is demonstrated in the graphs opposite, showing the trends of employees and payroll.³ Naturally, these trends were interrupted by circumstances growing out of the depression. But, serious as is this setback, there is nothing to indicate that the long-term upward trend will not continue. This has already been resumed.

Productivity of Labor.—Efficiency, consistent with safe and wholesome working conditions, has been an objective of the Bell System from the beginning. On the whole, however, the continual improvements in instrumentalities and methods have been made to permit of extending the scope or improving the quality of the service and not primarily to increase labor productivity.

Naturally, many new arrangements and methods reduce the labor required for specific operations—the dial switchboard illustrates this. Furthermore, many changes introduced solely to improve service lessen the work involved in the operations concerned. For example, improved transmission between customer and operators reduces errors and repetition of orders and reports; this, in turn, reduces the effort required to complete a connection. Improvements in "Information" switchboards and the provision of more complete and simplified records for the use of operators who supply information regarding telephone numbers, changes, moves, etc., have made it possible to perform this service more promptly and completely and with less work-time per call. Another example is the creosote treatment of telephone poles, which lengthens the life of the poles and reduces the amount of work required for inspection and replacement.

Since, however, one of the fundamental policies of the Bell System, and one which has been adhered to from the beginning, has been to make every effort to provide security of employment, the introduction of technological changes has been undertaken in each case with the most careful consideration of the welfare of the employees involved. As changes occur in instrumentalities or methods, the employees affected are generally absorbed elsewhere in the business by retraining and reassignments, usually in the same locality.

The technological change which may be said to result in actual loss of jobs is the introduction of the dial switchboard. For the most part, the operators released are those in manual central offices who were engaged for the period preceding the conversion of these offices to dial. These separations are scattered and their

³ Entered as "Exhibit No. 2570", see supra, p. 16641.

number is not large in relation to the operating force as a whole. They are offset, in part, by increased work for men. Except for the dial program, specific technological changes have rarely caused employees to lose their jobs.

Because of the general interest in the dial, there follows a discussion of that subject at some length.

The Dial Program.—A fundamental of forward looking management is the careful timing of changes to permit of steady progress with a minimum of fluctuation in employment, as well as in overall operating results, both for the short period and the long pull. The dial program was so planned. A large proportion of the change was accomplished during the period of expansion in the 20's when most of the employees displaced by the change could be absorbed within the business and those who could not, found relatively little difficulty in locating jobs elsewhere. During the depression the rate of introduction of new dial offices was reduced to a minimum. On the whole, the introduction of the dial has proceeded at a moderate rather than a rapid pace.

Large numbers of operators are needed with the dial system. This is frequently not realized, perhaps because of the nature of the dial itself and its original designation as "automatic". The dial system substitutes electromechanical processes for some, but not all, of the manual operations. In a dial area, operators are needed to assist customers who dial incorrectly or who require other help. Manual or dial, there is equal need of operators for many special services—among them, interception of calls on changed or discontinued numbers and supplying information about new telephones or telephone numbers in distant places. Also, large numbers of operators continue to be required for handling toll and long distance calls. The same is true of operators at private branch exchange boards, of whom there are about as many in the country as telephone company central office operators. On the whole, it is expected that the number of operators will increase, rather than decrease, with the growth of the business.

Conjecture as to the number of operators that would be required today, whether more or less, had the dial switchboard not been introduced, is futile. The present-day scope, quality and price of telephone service would be impossible under all-manual operation. The change to dial was inevitable for that reason alone—the limitations of the manual switchboard. The dial system, like many of the other technological improvements discussed, overcomes these limitations and by making continued growth possible, increases employment opportunities in the aggregate over the long term.

Discussion of the effect of the dial on employment is not complete if confined to operators. While, on the one hand, the conversion of individual central offices to dial operation displaces operators at the time, on the other hand the day-to-day operation of the dial system makes for more employment of men, as well as in the manufacturing, construction and installation aspects of the business. Moreover, under dial operation there is an increase in the complexity of equipment and practices, with the result that greater knowledge and skill are required of the employees, both men and women, with resultant higher wages.

In dealing with the specific problems involved in the readjustment of the operating force when individual central offices are changed to dial operation, management is constantly endeavoring to avoid adverse reaction on the employees and takes the utmost care in planning and carrying out the necessary program in each case. Usually the replacement requires the construction of a new building and the manufacture and installation of the necessary equipment. Plans for the conversion, therefore, must be under way some 2 to 3 years in advance of the actual change. The methods used are perhaps unique in some respects and a brief mention of the principal ones may be of interest.

As a first step, well in advance of the probable date of conversion, forecasts are made of force requirements up to and following the conversion. A thorough-going survey is made of placement opportunities for the operators likely to be affected by the conversion. On the basis of these estimates and of the practices outlined below, a program is developed which coordinates all pertinent factors so that the force will be of requisite size at all times and the number of operators released after the conversion will be held to a minimum. This program, of course, is modified from time to time as required by changing conditions.

Usually, most of the employees on the payroll at the time the dial program is started can be given assurance of continued employment; this is partly because the force progressively reduces itself by normal resignations and partly because of the opportunities for reassignments. At the earliest possible date each member of the force is made thoroughly conversant with her probable status after the office changes to dial operation.

During a period extending from a few months to a year or more prior to the conversion, all losses from the force are replaced with temporary people who are engaged with the understanding that their employment is for the period up to the time of the conversion. These temporary employees are chiefly people who desire work for limited periods, such as persons taking a year out from school or expecting to be married soon, or ex-employees who are willing to return for a few weeks to a few months. Sometimes part of the force losses prior to conversion are replaced with employees borrowed from other central offices in the same or other cities. Many other measures are employed to minimize force requirements prior to the conversion date and the number of employees to be released after such date; an example is the postponement of most of the vacations until after the conversion. Employees released are given regular vacation pay, and, since the early 1930's, generally lump sum separation allowances.

Over a period following the conversion, the operating force is readjusted to the work requirements of the new basis. A large proportion is retained for services which continue to be handled manually, such as customer assistance, information, toll and long distance. Scheduled transfers and postponed resignations take effect. Borrowed employees return to their home offices. Part or all of the temporary employees are released, some of whom go to positions which have previously been arranged for on private branch exchange switchboards.

There are many other interesting aspects of the adjustment of the operating force in connection with dial conversions, but the foregoing gives some picture of how this problem is handled with a minimum of unfavorable effect on the employees.

Other Employment Considerations.—In addition to increasing employment opportunities, technological development benefits labor in other ways. That labor has shared in the fruits of technological development is demonstrated by the large and consistent proportion of the revenues of the business which is expended for wages and associated benefits. The wage rates themselves have increased greatly and today are higher than ever before, notwithstanding the considerable reduction in hours.

The rise in the average weekly earnings of telephone employees is shown in one of the graphs opposite page 12. This rise is chiefly the result of increases in basic wage rates, but other factors have influenced the trend, such as greater length of service and increasing proportion of more highly skilled jobs.

Other advances which labor has gained with the progress of the business are longer vacations, increased number of holidays, greater security of employment, more liberal payments during periods of sickness, more wholesome and safer conditions of work, and similar betterments. Important as is the Bell System Benefit and Pension Plan in furthering the economic security of the employees and their dependents, it will suffice merely to mention that here.

Finally, it may be pointed out that while technological development often decreases the number of employees required for individual operations, usually the changed operations require greater knowledge and skill on the part of the employees. In other words, technology in the telephone business has the effect of "up-grading" the workers with, of course, a corresponding favorable influence on the trend of wage rates.

1933 Period.—The whole of the foregoing, discussing broadly the extent to which employment opportunity and welfare of labor are dependent upon technological advances, deals with the general matter from the long-term viewpoint. This is in accord with the broad approach which the Committee has suggested.

In the Committee's advance statement specific reference is made to the failure of substantial recovery since 1933 to eliminate unemployment. The following has to do with that reference.

Broadly stated and as indicated in the graph opposite page 4, recovery of revenues, of services (telephones-conversations) and of total wages has been at about the same rate; in fact, services to customers (telephones-conversations) and wages to employees have increased somewhat more rapidly than have the revenues of the business. There is no need, therefore, to refer further to these relationships here.

On the other hand, the number of employees has not increased as rapidly as these other factors. To understand the reason for this, and also the reason for the relatively greater drop in employees and in payrolls from the high of 1930 to the low point, it is necessary to outline the situation prior to 1930, and the situation as it existed during the depression years.

The telephone industry, while relatively stable, is none the less directly affected by the level of business in general. Its activities fall into two broad divisions:

one, day-to-day operations; the other, construction of plant to meet future needs. Construction is naturally less stable than operations.

There can be no back log of unfilled orders—telephone connections between customers must be completed promptly as requested. Facilities must be provided in advance. Personnel must be engaged and trained in advance.

Under this obligation of preparedness, and with the heavy demands for service in the 1920 decade, a large construction program had to be carried on to insure adequate physical facilities. In this period, annual gross additions rose from a level of 200 million dollars to 600 million dollars per year; in all some 3.5 billion dollars of construction was completed as compared with one billion a decade earlier. The investment in plant rose from 1.2 billion at the beginning of 1920 to 3.7 billions at the end of 1929.

To assure preparedness in personnel, large numbers of new employees had to be engaged and trained, and in advance. Thousands of these were needed simply to maintain the existing force—during the 20's, for example, resignations and other normal losses amounted on the average each year to more than 40 per cent. of the force. The losses are shown in the graph below.¹ These had to be replaced, and other thousands of new employees had to be engaged for the increased requirements. By the end of 1929, there were about 90,000 employees with less than one year of service—25 per cent. of the total force. On the average, 40,000 employees were engaged in the construction of plant necessary to care for current growth.

The result of all these factors was that by the end of 1929 the Bell System personnel reached a total of 364,000. This was clearly an abnormal situation and not an appropriate yardstick with which to appraise subsequent developments.

With the depression, and in 1930, came a sudden, sharp drop in demands for new facilities and a slowing up in telephone usage. To make the force situation more difficult, normal force losses decreased materially, incidental absences dropped, the experience and resulting skill of the forces increased and operating conditions generally become easier. These changes at once produced a surplus of people and this situation became progressively more acute.

As the work volume dropped, adjustments had to be made to bring the forces more in line. This was done in an orderly way and with the utmost regard for the welfare of the men and women. Construction was carried on for a period at existing levels but had to be curtailed as more and more telephones were discontinued and usage reduced. Intensive sales and other promotional activities were carried on. Thousands of employees were retained by spreading the available work and other thousands by introducing productive "made" work.

Despite all efforts, work requirements dropped steadily. There was simply not enough work to go around. Had the System released all employees not actually needed, instead of spreading work and providing made work, there would have been more than 60,000 fewer employees at the bottom of the depression; this condition prevailed in varying degree throughout the depression.

The readjustments of the force took place gradually and over a period of years. For the most part the readjustments occurred by not making replacements of natural losses—resignations, deaths and retirements. Layoffs because of lack of work and dismissals because of unsatisfactory work actually averaged a lower percentage of the regular force during the depression than during the previous 10 years. This is shown by the preceding graph. Those affected were chiefly the short service employees, not the older people.

Employees laid off were given their regular vacation pay in advance and, in addition, it became increasingly the practice to pay lump sum allowances at the time of separation in order to assist them in their readjustments.

In brief, as the situation existed at the time, all was done that soundly could be done to lessen the reaction.

Here, then, stood the situation late in 1933 as losses in telephones and shrinkage in usage and in revenues stopped. There was appreciable excess plant, the result of the loss of 2,600,000 telephones and the continuing of construction in the interest of employment—there remained an excess in the force because of the desirable practice of spreading of work—there were those on "made" work. The force as a whole had an experience factor theretofore never attained. In 1933 the average length of service was 10 years; the 1928-1929 average was 5½. During this period there were no new technological changes which might have tended to aggravate the immediate unfavorable employment situation.

With this greater experience—with plant margins beyond any that existed before—with little of the day-to-day activities of the organization associated

¹ Entered as "Exhibit No. 2671," see supra, p. 16646.

with the problems incident to growth—with incidental force absence small, and with the continuing improvements in management procedures and practices—the effectiveness of the entire organization became progressively greater.

Therefore, as the losses in telephones were regained, as usage became greater, and as the number of dial telephones increased, the added work was handled with relatively few additions to the force, particularly as during the early part of the "pick-up" period there was less and less spreading of work, until the force as a whole worked full time—40 hours.

Stated briefly, as the work load dropped the forces were not readjusted downward to the full extent of this—at the low point, as previously mentioned, there were some 60,000 employees over and above the actual requirements. These had to be gradually absorbed; and there was little new plant required. This explains why the increase in number of employees has not kept pace with the increase in telephones, usage and revenues. On the other hand, the number of employees has increased over the past few years and, as growth continues and the telephone markets are further developed, it is expected that this upward trend will continue. More and more people will be required to meet additional construction needs and for day-to-day operations.

CONCLUSION

In conclusion, it is clear that the provision of communication facilities adequate to care for the expanding and ever-changing social and business needs of the nation can be met in no other way than through a close adherence to the established policy of prompt recognition, development and introduction of essential technological changes making for cheaper and better plant as well as for more efficient administration and operation.

As to the effect of these changes on employment, the number of people now employed in the Bell System is certainly far greater than it would have been had the art remained static. Opportunities for employment have been enlarged. Higher wages have resulted, along with shorter hours and many other betterments in working conditions.

The meeting of Bell System objectives of the best possible service of broadest scope at lowest cost consistent with fair return and just treatment of employees has been possible only as a result of taking full advantage of these technological advances.

EXHIBIT No. 2605

[Submitted by the United Electrical, Radio, and Machine Workers of America]

STATEMENT OF JAMES B. CAREY, GENERAL PRESIDENT, UNITED ELECTRICAL, RADIO AND MACHINE WORKERS OF AMERICA¹

In 1937, according to the U. S. Census, the electrical manufacturing industry (not including radio, refrigerators and other major appliance) was the 5th largest on the basis of number of employees; 6th largest on the basis of value produced; and 3rd largest on the basis of "value added by manufacture."

In addition to its being one of the largest industries, it has been growing more rapidly than industry generally in the United States since 1899. This is true on the basis of either workers or amount of products. In 1899, the electrical industry represented 0.9 percent of all the workers employed in manufacturing; in 1937, it represented 3.7 percent. In 1899, .92 percent of all the value added by manufacture was in the electrical industry; and by 1937 this had risen to 4.05 percent, which thus shows a relatively greater rise than employment.

Electrical & Radio Industry as Percent of Total Manufacturing

Year	Value Added	No. of Workers	Year	Value Added	No. of Workers
1899	.92	.9	1925	3.51	3.1
1904	1.23	1.3	1927	3.90	3.1
1909	1.38	1.4	1929	4.30	4.0
1914	1.91	1.8	1931	4.11	3.6
1919	2.42	2.5	1933	3.88	3.9
1921	2.82	2.5	1935	3.71	3.1
1923	3.00	2.5	1937	4.05	3.7

NOTE.—Prior to and including 1929, the Bureau of the Census included radio in the electrical manufacturing industry, and for consistency, we have added radio to electrical from 1931 to date.

Of special significance in any discussion of technology is the unique position which the electrical manufacturing industry occupies in the total industrial picture, for this industry produces much of the apparatus which, especially in recent years, has brought about technological change in other industries.

For example, in the last 5 census years, almost \$150,000,000 worth of control apparatus were produced—*control apparatus*, which rose from 2.1 percent of

¹ Italics indicate words written in in pencil; words scratched through are indicated by line type.

total electrical production of 2.5 percent, and approximately \$620,000,000 worth of motors, motors which rose from 10.1 percent of the total production to 15.1 percent. Of these two items, it is probably safe to say that the majority of the first, control apparatus, and a sizable percentage of the second have gone to other industries, where they have replaced more primitive apparatus.

In addition to the control apparatus mentioned above, there is a separate industry classified by the census as "INSTRUMENTS AND APPARATUS, PROFESSIONAL, SCIENTIFIC, COMMERCIAL AND INDUSTRIAL," which, according to "Industrial Instruments and Changing Technology" (WPA National Research Project, Report # M1, October, 1938) is being more and more refined on electrical principles. This industry, between 1909 and 1929, increased its production almost fifty-fold, and in the latter year sold \$30,000,000 worth of products to industrial concerns. It is pointed out, however, that whereas in 1919, for each thousand dollars \$1,000 invested in machinery only \$3 was spent for control instruments, by 1935 for each thousand dollars of machinery purchased, there was purchased that figure had reached \$14.37 of control apparatus.

The second important factor along this line in this connection is the fact that direct controlling apparatus, such as tachometers, flow meters, etc., as opposed to strictly indicating and recording instruments, are becoming increasingly important. Thus, in 1923, only 7.7 percent of all instruments produced were control instruments, but by 1935 control instruments represented 33 1/2 percent of all new instrument sales. "These increasingly important industrial instruments represent a type of equipment which is relatively inexpensive and serve to contribute substantially toward reducing costs of production and toward increasing effective capacity of equipment already in use, thus obviating the installation of new machinery. As a safeguard against break-down, instruments serve to reduce the volume of repair work. Through securing uniformity of operation, they help minimize the wear of machinery and extend its normal life.

It must be remembered that, conversely, technological changes in other industries brought about through products developed in the electrical industry will in turn reflect upon the production and employment in the electrical industry itself.

Thus the Federal Power Commission reports, in "National Power Survey: Interim Report, Powers Series #1, 1935," that steam-power units installed in central power stations in the period of 1931 to 1934 averaged over 30,000 kilowatts in capacity, as against approximately 15,000 kilowatts per unit in 1921 to 1925. "The original investment per unit of capacity is a great deal smaller for large steam-electric generating stations than for small ones, ranging from \$135 to \$150 per kilowatt for stations of a capacity of 2,000 kilowatts to \$92 to \$115 per kilowatt for stations of 200,000 kilowatts. The cost per unit of capacity in the case of boilers capable of producing 1 million pounds of steam per hour is less than one-half that of a boiler with one-tenth that capacity.

"Likewise, in Diesel plants investment per unit of capacity varies inversely with the capacity, declining from \$230 to \$106 as the capacity increases from 100 to 10,000 kilowatts."¹

"Again, wherever large-capacity electric motors are required, similar economies in investment per unit of motor capacity are secured as the capacity of the motors increases."²

"Another outstanding development in the power industry has been the growing use of the 'topping' technique, whereby the exhaust steam from high-pressure, high-temperature turbines is utilized by being discharged into the steam headers of lower-pressure units. In this way it is possible to increase the capacity of existing stations from 40 to 90 percent without an increase in fuel requirements and without corresponding additions to plant and equipment. Instead of replacing all of the obsolete units in the recovery years since 1933, replacement of certain key units was thus sufficient to secure the required modernization of equipment and expansion of capacity. 'Topping' units represented more than 75 percent of the total turbine capacity installed in the period from January 1936 to May 1937 in central stations using pressures of 1,000 pounds and over and about 30 percent of all turbine capacity installed using pressures above 400 pounds."³

All the above have had the effect of lowering the amount of employment and production in the electrical industry.

The electrical industry, for all practical purposes, could be termed a concentrated industry. Of 29 states reported in the U. S. Census, 95 percent of the

¹ "Effects of Technological Developments upon Capital Formation"—National Research Project, p. 6.

² "Effects of Technological Developments Upon Capital Formation"—National Research Project, p. 4.

³ "Effects of Technological Developments Upon Capital Formation"—National Research Project, p. 8.

total electrical products manufactured are produced in 12 states. Of these 12, 9 which are located north of the Mason-Dixon Line and east of the Mississippi River produce 87 percent of the total production. It could be pointed out further that within these states there are rather decided concentrations in limited areas, such as Philadelphia and Pittsburgh, in the State of Pennsylvania. Furthermore, the industry is concentrated from the standpoint of the importance of major companies; General Electric, Westinghouse, and Western Electric, for example, annually produce between 25 to and 35 percent of the total production.

In *The Structure of the American Economy*, the National Resources Committee reports that 44.4 percent of the total value of production in the electrical machinery apparatus and supplies industry was produced by the 4 largest producers. The tabulation which follows points out this fact to an even more startling degree, for whereas only 4 percent of the 1,400 plants in the electrical industry had an annual production in 1937 of \$5,000,000 or more (and it must be remembered that this 4 percent includes in many cases more than one plant of a given company, such as General Electric) this 4 percent employed 51.7 percent of all the wage earners, and produced 57.6 percent of the value of products.

Electrical Industry 1937 Classified by Value Produced—Percentage

Value Produced (\$000)	Number of Establishments	Wage Earners	Value of Products	Value Produced (\$000)	Number of Establishments	Wage Earners	Value of Products
TOTAL.....	100.0	100.0	100.0	250-499.9.....	12.6	4.4	4.0
5-19.9.....	13.2	0.2	0.1	500-999.9.....	9.8	7.7	6.3
20-49.9.....	14.4	0.6	0.4	1,000-2,499.9.....	9.3	14.5	12.8
50-99.9.....	14.7	0.8	0.9	2,500-4,999.9.....	4.9	16.5	15.3
100-249.9.....	17.0	3.2	2.5	5,000 & over.....	4.0	51.7	57.6

In the radio industry, 9 out of 162, or 5.6 percent of the plants, produced in excess of \$5,000,000. They employed 47.5 percent of the wage earners and produced 52.1 percent of the total production.

Radio Industry 1937 Classified by Value Produced—Percentage

Value Produced (000)	No. of Establish't.	Wage Earners	Value of Products	Value Produced (000)	No. of Establish't.	Wage Earners	Value of Products
TOTAL.....	100.0	100.0	100.0	250-499.9.....	8.6	1.8	1.8
5-19.9.....	6.2	0.05	0.1	500-999.9.....	17.9	8.4	7.6
20-49.9.....	11.7	0.3	0.3	1,000-2,499.9.....	13.0	13.8	13.0
50-99.9.....	10.5	0.5	0.6	2,500-4,999.9.....	11.1	28.0	23.6
100-249.9.....	15.4	1.5	1.6	5,000 & over.....	5.6	47.5	52.1

Both of these factors—concentration geographically and concentration according to size of plant—exert a strong influence on technological change in our industry; the first, because it allows changes in technique rapidly to pervade the entire industry; and the second, because the major companies are in a better position to spend money on research, and due to their large surpluses immediately to put into effect in their plant any practical results. *The importance of the latter is well stated in the following quotations:*

"Aside from the fact that the availability of large-capacity equipment provided the technological basis for the tendency toward a concentration of production in fewer and larger plants, the trend toward larger-capacity units was accompanied by decreases in equipment expenditures per unit of capacity."⁴

"While the transition to large equipment units means a smaller capital outlay per unit of capacity, it permits at the same time further economies in the utilization of the equipment. In many cases large-capacity equipment will, for instance, justify the use of refinements and of auxiliary devices which result in improved efficiency of operation. The advantages of large-capacity units are also often due to greater mechanical efficiency. Furthermore, the operation of large machinery involves the use of a considerably smaller amount of fuel and also of labor

⁴ "Effects of Technological Developments Upon Capital Formation"—National Research Project, p. 3.

per unit of capacity or of output than is called for in the operation of smaller equipment units.

"In addition to those direct economies brought about by the introduction of large-capacity units, there are indirect ones, such as those associated with installation costs per unit of capacity. Floor space required per unit of capacity is much smaller for larger than for smaller units. Saving in floor space clearly implies a smaller volume of plant construction to secure a given productive capacity. There are similar economies in transportation costs per unit of capacity as larger-capacity units are used.

"The obvious implication of the trend toward larger-capacity equipment is that during the recovery period after 1933—as idle plants were being put into operation and as old obsolete machinery was being replaced—considerably smaller capital outlays and less construction of equipment were required than in the middle twenties to secure the same or even an increased volume of output."⁵

Regarding the second point mentioned above, the question of research in relationship to large companies, the report of the National Research Project, entitled, "Industrial Research and Changing Technology" points out that the electrical industry was one of the first to engage in large scale research. At the present time, the electrical industry is the fourth largest industrial group as to research, and accounts for approximately 7 percent of the total industrial research employment in the United States.

Radio, another branch of our industry, at present accounts for approximately 2.5 percent of industrial research employment.

Furthermore, between 1927 and 1938 research employment in the electrical industry has grown 58 percent, while research employment in the radio industry has grown 1,600 percent.

Regarding the concentration of research within these specific fields, the report states that 18 companies, which represent 25 percent of all electrical companies conducting research, employ 82 percent of the research workers.

In radio, 5 companies, which represent 25 percent of those doing research, account for 83 percent of the research employment.

Finally, among the 45 largest employers of research workers, there are 6 firms in the electrical and radio field as well as 2 others whose secondary production in the electrical apparatus division is very great.

In relation to large plants, another factor is of great importance. These concerns have, for several years, been experimenting with job specifications, and this process has perhaps been given wider acceptance in our field than in many other industries. In this manner, they have been able to break down jobs into a number of minor operations, and on the basis of classification of these minor operations the workers are hired and paid. Thus, instead of hiring a machinist, for example, who is unquestionably a skilled worker and receives much higher rates of pay, new workers are today hired as punch press operators, screw machine operators, etc. at considerably lower rates. This tendency has reached alarming proportions, for the *ratio* rate of skilled workers to the total labor force is continually dropping. In fact, *dead* many previously skilled workers have today become, by definition and in fact, semi-skilled workers. We estimate that today less than ¼ of the employees in our industry are in the skilled classifications. The following table will give some idea of the importance of these classifications:

Skilled.....	78,000	21 percent
Semi-Skilled.....	196,000	52 percent
Unskilled.....	105,000	27 percent

(These classifications include the same occupations as those of the Bureau of Labor Statistics.)

The productivity of American workers has been increasing steadily. If 1899 were considered 100 percent, productivity per wage earner was between 151 percent and 155 percent in 1927, according to *Recent Economic Changes*. There is no reason to believe that since that time productivity has declined or has even decelerated.

Regarding one branch of our industry, *Production, Employment and Productivity in 59 Manufacturing Industries*, Report # S1 of the National Research Project, states that the output per man hour in the electric lamp industry rose from 25.4 in 1920 to 108.2 in 1931, using 1929 as 100.

Working only from 1929 to date, we have found the following to be true of our industry. Taking 1937 as 100 and considering the entire industry—that is, electrical machinery apparatus and supplies, radios and parts, refrigerators and

⁵ "Effect of Technological Developments Upon Capital Formation," National Research Project, p. 5.

other major appliances—we find that the units produced in 1929 were 108.5 which dropped to 39.3 in 1932, and was 74.5 in 1938 and 99.7 in 1939. Hours worked per week are now about 25 percent under 1929, and employment is approximately 16 percent under 1929. However, production per man is 10 percent over 1929 and 18 percent higher than 1937. Production per man hour is, at present, almost 36 percent higher than in 1929 and 19 percent higher than in 1937. The greatest gain made in productivity was in the heavy section of the industry, that is, electrical machinery and apparatus, where production per man is now 23 percent above both 1929 and 1937, while productivity per man hour is about 32 percent above 1929 and 29 percent above 1937.

In radio, productivity in 1938 was higher than in 1939, but in 1939 productivity per man is still almost 36 percent above 1937, and over 100 percent higher than in 1929. Practically the same is true of productivity per man hour.

In the appliances and miscellaneous field, productivity per man is slightly less than it was in 1929, but is about 3 percent better than 1927, while productivity per man hour is 4 percent better than 1927 and 28 percent better than 1929. (See Tables 1 to 5 following.)

Using a different method of computation, and considering only the census data of the electrical machinery, apparatus and supplies industry, we find the following: Productivity per man-hour, with 1929 being considered as 100, rose to 132.5 in 1931. There are various reasons for this, among which are the closing down of less efficient plants, the closing down of less efficient departments of plants, concentration of production in the most efficient units, laying off all but the most "capable" workers, intensification or speed-up of work, and the introduction of more mechanical processes. By 1933 productivity was back to 122.8 and dropped another 2 percent by 1935, and then rose in 1937 to 122.7. We estimate that in 1938 it had again risen to 125 and in 1939 reached a peak of 137.5. (See Table 6 following.)

¹ BLS Spliced.

* UE Estimates.

² Based on Sales.

On the basis of the above productivity figures we can point out the following:

- 1) The same amount of electrical machinery, etc., as was produced in 1929 can now be made with about 24 percent fewer workers.
 - 2) The same amount of radios, etc., as was produced in 1929 can now be made with about 50 percent fewer workers.
- In addition—and perhaps more important—is the fact that if the number of hours worked per week were now raised to equal the work week prevailing in 1929:
- 1) The electrical machinery branch of the industry could produce an equal volume with $\frac{1}{3}$ of the labor force.
 - 2) The radio branch of the industry could produce an equal volume with about $\frac{1}{4}$ of the labor force.

To put this data in still a different form, if the labor force of 1929 in our industry (machinery, apparatus, radio appliances, etc.) were now employed on a 35-hour week, the volume of production would be about the same as in 1929; and if the present work week were used, production would be approximately 10 percent greater than 1929.

Should the argument be advanced that productivity figures based upon the units produced are invalid due to price changes, the following points from the tables previously submitted should be worth noting.

For the entire industry, the labor cost per \$100 of value produced has dropped about 15 percent between 1929 and 1939. In the heavy branch of the industry, that is electrical machinery and apparatus, labor costs have dropped about 19 percent. In radio the drop has been only about 2 percent and in the appliances and miscellaneous products, the drop has been approximately .5 percent.

This would indicate that whether we calculated productivity on the basis of units, or value produced, there has been an increase over the past 10 years in all lines.

We must, furthermore, point out that whether we consider productivity on the basis of units or value, or whether we consider productivity per man or per man hour, wages have not kept up *with productivity*. Between 1929 and 1939 the average weekly wage for the entire industry has dropped approximately 5 percent, while the productivity figures, as mentioned above, have gone up. In the heavy branch of the industry wages dropped 2 percent; in radio they are slightly above 1929, and in the appliances and miscellaneous field the drop has been over 15 percent.

Present technological trends are not so revolutionary as the introduction of steam or electricity. "These technological changes are directed primarily at improving the existing technology . . .".⁶ In many cases there is no change in a machine itself, but in the attachment of a controlling mechanism. In many cases it does not effect the producing mechanism at all but consists of an improved raw material.

Technology affects the worker in many ways. By simplifying operations it reduces skills, allows time study norms to be easily established and results in lowered total employment, lower wages, and loss of skill. It also increases the relative proportion of women employed and affects to a great extent the age distribution of workers.⁷

The concluding section of our report will cite specific instances in our industry which demonstrate all the above conclusions.⁸

The following excerpts of reports sent to the National Office of the U. E. give a much better picture of technological changes in our industry than several volumes of derived statistics.

1. From a man who has worked for 5 years in an instrument shop in New York City.

"I have been employed as instrument-assembler since September 1935.

"About one year ago the following labor saving machines were installed:

- 1) One Warner & Swasey Turret Lathe #4, model 1933, reconditioned, to replace on Engine lathe.

On operations at present performed, double output per man-hour, setting-up time included in the new working hours. This machine has capitalized its cost after about ½ year of operation.

- 2) One high speed 4-spindle drill press, to replace one 3-spindle drill press of less power and speed.

Output per man-hour increased about 10 percent.

- 3) One Pratt & Whitney M-1115 Multiple Drill-press with 16 adjustable spindles, to perform jig-drill work, formerly done on the 3-spindle drill-press.

On operations at present performed (up to 8 spindles used simultaneously) output per man-hour increased on some parts as much as 10-fold, due to less jiggling and due to drilling all holes in one stroke; average increase on all operations now performed on this unit about 4 to 5-fold.

⁶ "Effects of Technological Developments upon Capital Formation", Works Progress Administration, National Research Project.

⁷ In September 1939 the Electrical Industry employed 15.8% more men but 32.2% more women than in September 1938. In Radio the increases were 29.7% for men and 60.1% for women. (Women's Bureau, U. S. Dep't of Labor).

⁸ At the Westinghouse plant in Pittsburg the output of two departments was increased 2¼ and 2½ times, with no increase in labor force, thru a rearrangement of machines combined with installation of some conveyors, etc. (C. G. Johnson, "Plant Layout Cashes in on Motion Economy" *Factory Management and Maintenance*, Vol. 92, No. 3 (Mar. 1934), pp. 114-6.)

- 4) One turret attachment for one of the two precision lathes, transforming the same for many purposes into a handscrew machine.
Correct data not available due to lay-off of former operator, who worked without attachment.
Inside of the last 3 months the following new tool machines were added:
- 5) Two Hardinge Cataract Precision lathes with turret attachments.
Without turret attachment each unit about 10 percent more effective, due to quicker speed-change and easier set-up performance.
- 6) Two Ettco Emric Drill presses, specially adapted for holding precision tapping attachments, to perform tapping operations formerly done with ordinary tapping attachments on a regular 1-spindle or on a 3-spindle drill press.
Probably 20 percent more effective, besides saving on broken taps due to automatic clutch.
- 7) Several single spindle drill presses, mainly for use in the assembly department, to cut down on unnecessary handling of material and assemblies.

"To keep the new machines working under full load, many jobs, formerly done under sub-contract by other concerns for the Corp., are now done in their own machine shop. *Total average increase of output per man-hour of the whole machine-shop department is about 50 percent.*

Total Number of employees one year ago 75; of those in machine shop 30 (40 percent).

Total Number of employees at present 102; of those in machine shop 38 (37 percent).

and this smaller percentage of machinists doing work, formerly done on the outside, decreasing thereby the jobs on hand by the sub-contractor, and fully supplying an assembly department, which itself is working more efficiently due to installation of department-drill presses, arbor-presses, and various jigs and fixtures. (A new W&S Turret lathe #4-1939 recently installed not calculated.)

"Production is mainly for U. S. Army and Navy (airplane, ship and submarine gauges). A reduction in the production-cost, even when expressed in a lower selling price will not increase the demand by as much as one unit."

2. Fuse production, Brooklyn:

"Previously it took 17 people and 17 operations to complete the making of a fuse. The company installed a machine, the Weiss machine, whereby 9 people can now complete the fuse."

3. Metal fabrication, Brooklyn:

"Bright acid dip: Process whereby metals are dipped in a bright acid solution and the process of hand polishing on a buff is eliminated."

4. From an electric plant in St. Louis:

"My work for the past 3 years has been assembling oil burners.

"When I began working here I could assemble, test, and inspect 5 burners in a 9 hour shift. Now I am able to carry 8 through the line in an 8½ hour shift.

"This has been accomplished by a technical simplification of the parts used thereby cutting down the cost of labor in the assembly line and also cost of materials. Formerly where two units were used for pump and cut-off valve now only one is used, as the cut-off valve has been incorporated within the pump itself at a smaller cost than the making of two units, and at the same time eliminating work in the assembly line.

"A number of other technical simplifications were made which cut down the work of assembling.

"As a result this has cut down my income as I now only work a little more than half the time I formerly worked.

"When such changes take place in industry the old men who have been displaced are kicked out and new unskilled men and sometimes women are brought in to run the machines at reduced wages, as the new machines take the skill out of the work and thus the trade becomes nil."

5. From an incandescent lamp works in New Jersey:

"In reply to your letter of January 30, 1940, I submit some facts. In and prior to 1929—it required the work of 6 girls to make a production of 3,500 packed lamps of various types per day working 8½ hours per day and receiving between \$23 and \$25 per week. Today it requires less than 6 girls to produce 15,000 per day in 8 hours. This is considered slow—we have new machines running 2,000 per hour or 17,600 per day. So much for girls. By moving machinery closer together and the use of mechanical arms, conveyor belts, etc. it also helped reduce the amount of men needed to maintain these machines."

6. From one of the largest producers of electrical machinery:

"My department, consisting of 48 employees, produces 20,000 double or 40,000 single magnets per week, working one shift of 8 hours, 5 days per week.

"A new system of manufacturing magnets is now being introduced and within a few months the new set up will be complete. Under the new set up, production will be the same but the number of employees will be reduced by 12. The chief difference in the new set up is that the magnets will now be poured into moulds instead of formed, thus eliminating such operations as cutting the steel for the magnets, forming the steel, hardening (in the new set up hardening will be accomplished by the use of cobalt), aging, gap grinding, shoeing, single magnetizing and measuring.

"Elimination of operations and the consequent reduction in the cost of production was not the reason for installing the new set up. The new type magnet is of a better grade and was already being produced by competitors."

7. The meter department of the same company:

"I have been employed in the meter department as a drill press operator for the past 15 years. In 1939, 33 men were employed in the machining of cast iron frames for meters, 3 8-hour shifts, 11 men to a shift. The total man hours for one week was 1320, and 15,000 frames were produced.

"In 1939 a machine known as the straight line machine was set up in the department. This machine is 60 ft. long, is composed of 75 tools, 18 jigs, 28 motors, 3 hydraulic pumps, 8 safety switches, and will perform 37 operations. This machine eliminates such man operations as drilling, tapping, milling, profiling, counter boring, and reaming.

"The machine operates 2 shifts a day, with one operator a shift, and the total production capacity is 240 frames per hour, or better than 19,000 per week for the 2 shifts, but due to occasional breakdowns the average production is 15,000 per week, or the same production as that of 33 men.

"Two new jobs per shift have been created—mechanics to service the machine, and repair in case of breakdown. Thus, 6 men produce the same number of frames per week as did 33 in 1938, a reduction of 27 men, and the man hours have been cut from 1320 to 240 per week."

8. From a lamp company in Ohio:

"(A) Stem Machine—Used for making the insides of standard electric light bulbs. The machine used in the past, produced 1600 stems per hour. The new machine will produce 2000 stems per hour, an increase of 400 per hour.

"(B) Three or four years ago an automatic feeder was built for a machine doing a certain operation on radio tubes. Before the feeder was used, 4 girls were required to serve one machine. After the feeder was put in operation, it required only 1 girl to serve 5 machines.

"(C) 15 years ago the Glass Division used 8 bulb blowing machines, producing 3500 bulbs per hour, and required the services of 50 girls per shift and 3 shifts per day,—150 girls for the 24 hrs. Today 2 new machines make 360 bulbs per minute, or 21,600 bulbs per hour, and use 100 girls for the 24 hours.

"(D) New production methods and modern machinery has enabled the management to decrease the working force by 81 men, and still produce more than at any time in the history of the company."

9. From a large battery plant in New Jersey:

"About 7 years ago there was a rolling mill in operation at our plant. This mill employed about 30 men. The company installed a Stickle Mill, with the result that they can now produce considerably more rolled metal and require only 4 men.

"In the Iron Load Department the elimination of 50 men was accomplished by the installation of more modern machinery.

"There is a department known as the 'Crane Department' which at one time contained twenty cranes. Each Crane required an operator prior to the invention of the automatic crane which runs without any human assistance. They now produce about double the quantity with 10 of these automatic cranes and no operators.

"In our plating department the installation of continual plating machines has enabled the company to do away with about 75 men.

"In 1938, with normal production, we had about 2000 people on the payroll. With peak production in 1937 we had only 937 people employed."

10. From a battery plant in Wisconsin:

"I have been working here for about 7 years, and in that time these are the changes that have been made. In the production of batteries there are lead plates

to be made and at the beginning of my employment the lead plates were made by hand, and now they are being made by a fast producing machine which is capable of turning out about 10,000 lead plates per 8-hour day, where when same plates were made by hand a man could put out about 1500-2000 lead plates per 8 hour day. Lead parts are to be made by a machine, whereas now they are being made by hand thereby taking off approximately 2 men per 8-hour shift. At the present time there are about 8-10 men trimming lead parts, whereas when the new machine will be in full running, these men will be taken off, as the new machine will produce lead parts that will not necessitate the trimming of the parts. A process of pasting of the lead parts were previously done by 6 men, now is produced by a machine operated by 3 men.

"In our Forming Room, work which was done previously by 5 men is now being done by 3 men on an 8 hour production basis. There are other operations which the writer is not familiar with, but are being handled by the firm in the manner as the aforementioned operations."

11. From a metal fabricating plant in New Jersey:

"I have been working for over 6 years on power presses, stamping aluminum, and have never been laid off, until this year. The reason for this is simply that before a man had to operate one machine, whereas now one man operates 3 or 4 machines. I have every reason to believe that in the near future one man might have to operate more than 3 or 4.

"Firstly, the company had installed hitch feeds, that is the hitch feed feeds the stock into the die. Secondly, they began to install automatic stops; that is if the machine jams, it will stop itself. Thirdly, as I was laid off they were contemplating the installment of electric eyes on the presses so that even if the stock came to an end, the machine would stop and a red light would flash on. And finally, they have improved the dies in such a manner that whereas before each die had one operation, now that same die does 4 operations, therefore, they can get much more work out with not quite half the number of men that they had previously."

12. From another shop in St. Louis the following changes are reported:

PUNCH SHOP MOTOR WORK

Production per day *was*—H D 1013-1237 stators (perf or notch); 8 min.—12,000 a day

Production per day *now*—H D 1013-1237 stators (perf or notch); 2 min. 5 seconds—47,200 a day

Was—H D 2023 Rotors (perf or notch); 8½ min.—13,600 a day per man per 100

Now—H D 2023 Rotors (perf or notch) 4½ min.—21,600 a day per man per 100

Was—H D 1410-8577 Rotors (perf or notch); 7½ min.—11,200 a day

Now—H D 1410-8577 Rotors (perf or notch); 3½ min.—28,000 a day

SMALL MOTOR DIVISION

Stator Core Division:—5 men—610 day. Formerly hand rolled band to hold iron together, new hydraulic press does 630 pcs. 2 men operating. All figures on 8 hr. day. This speed up within the last 30 days.

Punch Shop—motor work: Copper seg. bland 29,600 a day (formerly done) Now being done—55,000 a day. Protector Blank #3712, 24,000 per day formerly. Protector Blank #3712, 96,000 per day now.

Welding machines on dust shields Hydraulic Brakes since 1936—job of welding shoe guides on dust shields speeded up from 380 (ore welding) pcs. until today 768 (machine welding). Brake shoe group 1½ for 1 man was 400—1 man today—2400.

<i>Was</i> —	<i>Now</i> —
#MB 5075 short center weight blank (perf stack); and using 2 men at 4 min. per bunch—240 bunches per day	#MB 5075 short center weight blank perf stack—1:20 bunch or 730 bunches per day—1 man
#F C 309 retainer's blank perf. 2 min—48,000 day (formerly 10 min. 9,600 day)	#F C 309 retainer's blank perf. 1½ min.—64,000 day
1304 Valve Body Blank & perf 8,000 day	#1304 Valve Body Blank & perf 2½ min.—36,400 day
4084 Baffle plates assemble 28 min—3,400 day	#4084 Baffle plates assemble 6 min—16,000 day

TRANSFORMER—FARM LINE

Operation—lead assembly (making leads & adding terminal)
 1937—6 min to each lead
 1940—1.16 min per lead
 Farm line—boxing—assembling transformer element in tank straight hourly rate
 42 min each in 1937 (42¢ per hour)
 1940—34 min each

NOTES TO TABLES

Table 1.—Employment in the appliances field for the individual items are estimated for census years on the basis of production per man. Thus in 1937 there were 50,623 workers in the refrigeration industry who produced \$363,000,000 worth of products. In the same year there were approximately \$193,000,000 worth of electrical refrigerators produced in the refrigerator industry. Thus, if production per man was the same throughout, we can assume that approximately 53 percent of the workers were employed in the manufacture of electrical refrigerators. The same reasoning was carried out for each of the products listed. Intercensal years were then figured on the basis of B. L. S. indexes of employment.

Values were obtained by adding census items. A smooth curve of the ratio of census production to new orders as reported in the "Survey of Current Business" was constructed in order to interpolate intercensal years' production. Supplementary data published by NEMA, trade journals, and some company data were used as a check and to obtain the relative amount of electrical production in certain census branches, such as turbines and tools.

We have used production and employment of business machines as a whole, because the non-electrical parts of this industry would be balanced by certain other electrical machines in other fields, as electrical typewriters, duplicators, etc.

Table 2. Production.—The method of obtaining the intercensal figures on production are discussed above. Employment is based on B. L. S. data. The same method was followed to obtain production in the electrical machinery, apparatus, and supplies industry, and in appliances and miscellaneous products. The production in radio is based upon the census, and an article by Julius Weinberger, entitled "Economic Trends in the Radio Industry", published in the November 1939 issue of the *Proceedings of the I. R. E.*

Tables 2, 3, 4, and 5, derived indexes, were obtained as follows: productivity per man is obtained by dividing the indexes of production per man by the index of average weekly hours worked. Labor cost per \$100 value, is obtained by dividing the product of employment and weekly wages by the index of units produced.

"EXHIBIT No. 2606," introduced on p. 16746, is on file with the committee.

[Submitted by Brotherhood of Railroad Trainmen]

PRESIDENT'S DEPARTMENT

MACHINERY CREATES JOBS—WHAT OF IT?

There is considerable propaganda against shorter work-hour legislation, which propaganda although largely based on fact, draws erroneous conclusions. The argument is that notwithstanding the growing increase of labor-saving machinery, the percent of our population gainfully employed has actually increased. This is a fact. In 1880, 47.3 percent of our population, ten years and older, were gainfully employed. In 1930, 49.5 per cent of our population, ten years of age and older, were gainfully employed. However, those who argue against shorter work hours on the basis of these statistics, make a convenient omission of what happened between 1880 and 1930. The following figures showing the per cent of gainfully employed, ten years of age and older, are interesting:

1880.....	47.3%
1890.....	49.2
1900.....	50.2
1910.....	53.3
1920.....	50.3
1930.....	49.5

It will be noted from the above that there was an ascending per cent of gainfully employed from 1880 to 1910. From 1910 to 1930, the per cent of gainfully employed began to drop off and we find that by 1930, it had decreased to 49.5 per cent, which was almost the same percent as in 1890. Along with these figures, we should also consider the fact that we reached the peak of industrial production in 1929, but we had reached the peak of industrial employment in 1918.

These figures are explainable. In the years prior to 1930, there was a period of great expansion in this country. Railroads and highways were being laid out, factories were being built, and our frontiers were being expanded to the Pacific Ocean. During the rapid growth of this country, our problem was not one of unemployment, but rather one of a shortage of human beings. Naturally, in such a building period the per cent of gainfully employed was on the ascendency. Had this not been true, we would have had an unbearable amount of unemployment, because our population was also expanding rapidly. Five per cent unemployment in an expanding nation of 30,000,000 largely self-sustaining, rural, rugged individualists may not present serious social consequences, but the same per cent of unemployment in a nation of 127,000,000 people, living in a highly complex social and economic system, with hugh cities, vanished frontiers and "No Trespass" signs on all lands, gives rise to serious social problems. But now our factories are built, if not over-built, and our use of electrical power is growing out of all proportion to human employment. Strenuous efforts are being made to tear up railroad trackage and terminals rather than to expand them. This leveling off process is even extending to our population, and it is estimated that our population growth will become static within another decade or so. The above figures on gainful employment show that the leveling off process began on employment between 1910 and 1920.

I was interested to read the following statement in the *CHEROKEE (Iowa) COURIER*, republished from an Iowa newspaper sixty-three years ago, on December, 18, 1872. It follows:

"The House of Representatives at Washington last Thursday passed a land bounty bill that gives to each officer, soldier, sailor or marine, the right to enter a quarter section or any unoccupied lands including double minimum priced lands along lines of land grant railways, and procure patent at once in the regular way, and he becomes than as free as any holder of public lands to sell if he desires. It is said that there will be a good deal of opposition to the bill in the Senate."

In those days, the government was actually giving land away in order to get settlers to occupy it and thereby spread our frontiers. Does anyone know of anywhere in the United States today where good agricultural land is being given away? Instead of giving away land now, the present President of the United States and his predecessor, have found it necessary to promise the people that "no one in our land shall be permitted to starve." This is not a very complimentary goal for a nation possessed with greater wealth than any other nation in the world. Now, we are trying to prevent full use of the available agricultural land, on the theory of creating profits by artificially creating scarcity. If people were not suffering for want of food this might make sense. This brings us to another important factor which those who are arguing against shorter work hours

are overlooking. Through its spokesman, Mr. W. J. Cameron, the Ford Motor Company, in its weekly Sunday night radio broadcasts, has been giving some interesting facts, but also some very erroneous conclusions. Mr. Cameron points out that in 1870, it required 324 persons out of every one thousand of the population to produce what the consumers demanded, but in 1930, "with the machine predominant," as Mr. Cameron says, it required 400 persons out of every thousand. He concludes from this that the charge that machines make fewer jobs is completely refuted.

Mr. Cameron overlooks the fact that in 1870 this nation was mainly composed of an agricultural economy, whereas in 1930, it was an industrial economy. According to page 337 of the *WORLD ALMANAC* for 1933, 10,482,323 persons were engaged in agriculture in the United States in 1930. This was a little more than 8 percent of our total population. It is estimated that in colonial days the farm population constituted about 95 percent of the total, whereas now it is about 22 percent. If the modern farmers were given an opportunity to produce at full capacity, the change from an agricultural to an industrial economy would be even more pronounced. Fifty percent of our farmers produce 88 percent of the marketable agricultural produce. If given a fair opportunity, they could easily produce the other 12 percent, and thus eliminate half of those now engaged in agricultural pursuits.

When we consider that in the early days, such a small per cent of our population was engaged in industrial occupations, as compared with those so engaged today, the amazing fact is, not that there has been an increase in the per cent of those gainfully employed, but that the increase has been so small.

Why has this per cent of increase in gainful employment been so small in comparison with the great growth of industrial enterprise over agricultural pursuits? The answer clearly is, the use of machinery and the great technological achievements that have accompanied the Machine and Power Age. There are two ways of viewing this problem brought about by the change from an agricultural to an industrial economy, followed by the inevitable leveling off processes now under way. One view is that of the narrow-minded industrialist who ignores the sociological implications of these changes in our economic and social existence. The industrialist, such as Henry Ford, answers it as follows:

"One year when the (Ford) Company spent four million dollars for machinery, its employees increased by 20,000 men, and the pay roll by 48 million dollars. Another year when the Company spent nine million dollars for machinery, its employees increased by 40,000 men, and its pay roll by 88 million dollars. In another year when the Company invested 10 million dollars in machinery, employment increased by 37,000 men, and the pay roll by 76 million dollars. That was the invariable experience—the more machinery, the more men."

Such a statement cannot be considered as industrial statesmanship. Rather, it is a futile effort to chart the destiny of 127,000,000 people on the basis of what one sees in his own backyard. Mr. Cameron of the Ford Motor Company further asserts that industry has never employed, in round numbers, more than 8,800,000 persons. He states that industry, never having employed as many as nine million persons, is now being "asked to employ immediately an additional eleven million persons, 'or else.'" This is an important fact.

Industrialists claim that they will solve the unemployment problem if the government, the people, will let them alone and enable them to regain their "confidence." The Cameron viewpoint suggests that industry is now doing its full duty and that the great social problem of unemployment is not a problem for industry. If the government is not permitted to solve the unemployment problem and industry feels that it is unreasonable to expect it to give jobs to the millions of unemployed, then starvation seems to be the only alternative for a great portion of our citizenry. At the beginning of the panic, industry promised President Hoover to cooperate fully in maintaining wage and employment levels. Both then and before the panic struck, industry had the gold standard, "sound" money, extensive foreign trade, a strong durable goods market, a balanced governmental budget, freedom from governmental "interference," "confidence" and everything it is now asking for, yet the panic came and has lasted since 1929. Through Henry Ford's spokesman, industry now admits that the unemployment problem is beyond its capacity to solve. If industrial leaders would take their minds off profits long enough to realize that the fundamental law of self-preservation will eventually compel the social body to defend its own existence, they would realize that their rather egotistic attitude of self-satisfaction is leading them to self-destruction.

Mr. Cameron, with an air of self-satisfaction, asserts that his company has employed more men as it has installed more machinery. He creates the impression that the Ford Company has "done its bit" and will not be interested in the salva-

tion of society itself. But Mr. Cameron tells us nothing about the greatly increased productivity of the workers employed by his company to operate the machines it has installed. He does not tell us that in 1929, the *labor* cost of making an automobile door was \$4.00, but today it is only 15c. He has not told us that in 1929, it cost \$3.00 *in wages* for body framing one automobile, but today it costs 35c; or that in 1929, it cost \$3.00 to hand-finish the body frames of wood before paneling, but now it costs 20c. In other words, Mr. Ford is anxious to spend some of his fortune to tell the people, in a nationwide radio hook-up, what he is doing in the way of giving jobs to workers, but he is significantly silent as to what the workers are giving him in return for it as a result of their greatly increased productivity.

The director of the governmental survey known as the National Survey of Potential Product Capacity, Mr. Harold Loeb, is authority for the statement that "Productivity per worker has gone up from 1,648 (1913) dollars in 1869 in manufacturing, to 6,533 (1913) dollars in 1932. Per capita income has gone up from 277 (1913) dollars in 1890, to 282 (1913) dollars in 1932." This represents an increase of 296.4 per cent in dollar value of the workers' productivity, but the per capita income has increased by the pitifully small amount of only 1.8 per cent. Production per worker in our manufacturing industries has increased 71 per cent from 1919 to 1933, while the workers' share has decreased 6 per cent. While profits have increased 50 per cent, wages have decreased 40 per cent. With a 296.4 per cent increase in dollar value of worker productivity and only 1.8 per cent increase in per capita income, where has this wealth gone? Because profits and inflated capital structures have taken more than their share, this potential, not actual, wealth has been dissipated through the practice of non-production. These are some of the pertinent facts that Mr. Ford does not reveal to the public.

They are pertinent because they prove that as the workers have increased their productivity, instead of being given incomes sufficient to enable them to buy-back the real wealth which they have produced, it has been diverted into capital investment, factories, machinery, etc., thereby enlarging the workers' productive capacity, without correspondingly increasing his purchasing or consuming ability. Instead of the "prosperous" years preceding the panic, being years of improvident spending, they are marked as the period of the greatest savings in history. During this period, while housewives were spending \$34,700,000,000 on consumable goods, capital was spending \$53,900,000,000 on capital investment. Capital investment is savings. It is now clearly evident to any thinking person that such a course would eventually wreck the economic system. An important reason why the collapse did not come before 1929 was because of the debt-creating device of installment selling by which the workers were enabled to obtain a part of the wealth they produced, not as a matter of right, but by mortgaging their future earnings. In the face of this history, our "expert economists" are telling us that all we need to restore prosperity, is such "confidence" as will inspire greater investment in capital goods.

We now have the over-expanded capital structures, idle factories, machinery, etc., as well as the debts which will require the masses, for some years to come, to pay the "coupon clippers" instead of consuming or buying back the wealth which they may produce in future years. Not only do we have the idle capital structure and the debts, but for over six years we have refrained from producing some \$350,000,000,000 of real wealth which we might have produced had we listened to the voice of reason and common sense instead of the *bought* voices of "expert economists." Let me explain parenthetically that by referring to an over-expanded capital structure, I have reference to over-expansion from the standpoint of purchasing power of the masses, rather than from the standpoint of the needs of the people. From the standpoint of "profitable" markets, and we are still under a profit system, there is over-expansion of capital enterprise, as witness the idle factories, but from the standpoint of human needs, there is no over-expansion, except possibly in unimportant and isolated instances, such as four gasoline stations on one corner.

What has Mr. Ford learned from the history that has been written in his lifetime and more especially in the last decade? His recent announcement, in an obvious air of triumph, that Ford cars may now be purchased for \$25.00 per month, would suggest that he has learned little. The Ford view is the narrow view of the industrialist, without statesmanlike vision and apparently without serious concern for the welfare of the society which has made it possible for him to become one of the richest men on earth. If this matter is viewed with courage and vision and with a consciousness of social welfare, then Mr. Ford's propaganda to the effect that he has employed more men as he has bought more machinery, may well be answered, "What of it? The fact remains, that we still have some ten or eleven million unemployed in this country."

Unless we consider, as Mr. Ford apparently does, that the prospect of having some eleven million men permanently unemployed in this country is no concern of ours, we must cease confining our vision to our own backyard and undertake to arrive at some solution of the great social problems before us, if Ford automobiles are to continue to be sold. In looking at this problem from the social viewpoint, we must bear in mind the great changes that have taken place in this country, particularly with reference to the change from an agricultural economy to an industrial society which consumes an amount of electrical power energy, the equivalent of which could not be furnished by the muscular power of a half billion stalwart able-bodied men.

Recently the Machinery and Allied Products Institute published a pamphlet entitled "Ten Facts on Technology and Employment," in which the narrow Ford viewpoint is taken, that machinery is really solving our unemployment problem, rather than creating a problem of technological unemployment. After giving various facts, and the usual erroneous conclusions, this Institute successfully destroys its own case in the following words:

"If technological advancement did not make possible a greater volume of production the standard of living could be raised only by increasing hand labor. Had it been necessary to increase hand labor in the same proportion as production between 1900 and 1930, every adult man and woman in the nation and several million children would have been needed in jobs. It would have required more than 60 per cent of the entire population whereas only about 40 per cent ever seeks gainful employment, the remaining 60 per cent being constituted chiefly of women and children supported by the 40 per cent."

Thus, the Machinery and Allied Products Institute starts out to prove that labor-saving machinery does not destroy jobs and ends up by proving that were it not for machines and modern technology, there would not be enough adult men and women workers in the country to accomplish the work now being accomplished with extensive use of machines and power.

We have already noted the great reduction in the per cent of our population engaged in agricultural pursuits. In 1850, we had 12.6 farm acres for every man, woman and child in the country, but today we have only 8 acres for each man, woman and child. What has happened during the period in which our population has doubled and redoubled, while those engaged in a largely self-sustaining occupation such as farming, have not increased in proportion. Industry has been able to absorb some of these people, as Mr. Cameron points out. But also, as Mr. Cameron points out, we cannot expect industry to employ all of the unemployed, at least, not on the present schedule of working hours. During the time that our frontiers were expanding nationally, internationally, and industrially, the slack was taken up, but now the gap is ever widening. The proportion of gainfully employed engaged in manufacturing dropped from 30.5 per cent to 28.6 per cent between 1920 and 1930, according to "Recent Social Trends." Although machines and modern conditions have created many new jobs, the existence of some eleven million unemployed testifies to the fact that machines have not created a sufficient number of jobs to assure economic security for all. But those who argue that machines and modern methods have created new jobs, seem to overlook the fact that they have also eliminated many jobs. Data assembled by the United States Bureau of Labor Statistics, which may be found on page 311 of the 1936 *WORLD ALMANAC*, relating to employees per million of United States population, is most interesting. A few of these facts are as follows:

Employees Per Million of United States Population

	1850	1860	1920	1930
Agriculture.....	103,568			85,294
Blacksmiths.....	4,308			1,013
Boot and Shoe Workers.....	5,644			2,482
Cabinet Makers.....	1,611			472
Carpenters, Joiners.....	8,609			7,570
Hackmen, Drivers and Draymen.....	1,757			1,240
Harness Workers.....	982			62
Marble and Stone Cutters.....	907			186
Millers.....	1,199			316
Physicians and Surgeons.....	1,757			1,253
Sailors and Deckhands.....	3,044			527
Tailors, Dressmakers, Milliners.....		8,045		4,421
Tanners and Curriers.....	646			373
Wagon and Coach Workers.....	673			34
Wheelwrights.....	1,323		35	none

It will be observed that the above occupations are those which have been reduced or eliminated entirely because of the machine and modern conditions. Not the least surprising in the above table is the fact that the American people had more physicians and surgeons per million of persons in 1850, than in 1930. This is an awful commentary on modern society. No doubt, many capable doctors are now in the breadlines or are digging in the frozen ground for WPA. Of course, physicians and surgeons also are subject to modern trends which reduce employment in their ranks. Doctors in large city hospitals can now attend far more patients than the country doctors of 1850, who were forced to struggle through the snowbanks of the byways, rather than on the hard surfaced highways of today.

By carrying through to the present population the same per cent of the above workers who had such jobs in 1850, we find that if these jobs had not been reduced or eliminated and if the same per cent were now so employed, we would now have 18,246,471 occupied in the above callings. However, on the basis of the per cent so occupied in 1930, which undoubtedly would be smaller now, instead of 18,246,471 being employed in these callings, only 13,365,861 are now so employed. Thus, machines, technology and changed habits have eliminated 4,880,610 jobs in the above few callings. Narrow-visioned industrialists are constantly pointing out, through a favorable press and radio, that machines and modern conditions create new opportunities for employment, such as Mr. Cameron's illustration of four blacksmiths formerly being employed in a Michigan town, where now there are no blacksmiths, but 23 men are employed in garages, filling stations and tire and auto accessory stores. But these industrialists are not willing to portray a realistic picture by giving all of the pertinent facts, such as those herein set forth relating to the decrease in jobs in certain callings.

Mr. Cameron's illustration pertaining to a Michigan town is worthy of a more thoughtful analysis than he gave it. It is valuable because it refers to a small urban community, whereas the problem of unemployment in our modern technological society is too frequently considered only with respect to large urban centers. Let us attempt to complete the picture of this small Michigan town, which was only outlined by Mr. Cameron. On the basis of the year 1850 ratio of Harness Workers and Wheelwrights to Blacksmiths, there was approximately one Wheelwright and Harness Worker for every two blacksmiths. Thus, Mr. Cameron should have added two Wheelwrights and Harness Workers to the four Blacksmiths, making six, instead of four comparable former workers in this Michigan town. To make the comparison more accurate, there should be included those working in livery stables and feed stores, figures on which are not available to the writer, but certainly there would be at least one man working in the livery stable and one man working in the feed store. This makes a total of eight former workers, instead of four in comparative occupations in the Michigan town. Thus, the 23 garage, filling station and auto accessory workers represents an increase in the eight former comparable workers of 187.5 per cent.

We shall assume that in the interests of accuracy Mr. Cameron selected a representative community. Having this in mind, although Mr. Cameron's illustration shows an increase in jobs, he significantly omits to point out that from 1850, when these former jobs existed, to 1936, there has been an increase in the nation's population of approximately 452 per cent, while Mr. Cameron shows an increase in jobs of only 187.5 per cent.

But in the interests of completeness and accuracy, we should carry through the per cent of population employed as Blacksmiths, etc., in 1850 and determine approximately what number would now be so employed had we not abandoned the horse and buggy for the automobile. The picture cannot be made complete because of the absence of figures relating to feed store and livery stable workers, but the omission is in Mr. Cameron's favor. By comparing the number of Blacksmiths, Wheelwrights and Harness Workers per million of population in 1850 with the number so employed today, we find the number of these jobs per million of population was 615 per cent greater in 1850 than in 1930, as compared with Mr. Cameron's increase of 187.5 per cent in jobs in the Michigan town as a result of the abandonment of the horse and buggy for the automobile. If we assume that the automobile had never been created and we tried to use horses, buggies and wagons to do the work now being done by automobiles and trucks, there would not be enough Blacksmiths, Harness Makers and Wheelwrights in the entire world to fill these necessary jobs in the United States. Does this look like the automobile brought about a net increase in available work opportunities? "Horses and buggies" may yet be the means of humiliating the modern Bourbons and Tories who are so solemnly propounding the American Liberty League philosophy.

We could not intelligently consider this problem without referring to a very pertinent statement of Thomas Edison, who said:

"Human slavery will not have been fully abolished until every task now accomplished by human hands is turned out by some machine."

Dr. Ure, an expert English economist, advised the manufacturing classes of England, in the middle of the nineteenth century, that the goal of the manufacturers should be the development of machinery to the point where they could use the labor of women and children, which was cheaper than that of men, and that the ultimate goal was to displace all labor, as nearly as possible, through the development of the machine. With this goal in mind, why is it that there are not a greater number of unemployed than there is? The answer to this question is not a great compliment to our modern society.

In the early days when the overwhelming part of our population was rural, the major part of the population was essentially self-sustaining, that is, the farmer consumed most of his own production. The farmer of those days had far fewer urbanities to support than today. In 1870, there was one person engaged in agricultural occupation for each 6.5 persons in the nation. By 1930, there was one person engaged in agriculture to 11.7 persons in this nation. With the increase in the general population expanding out of all proportion to the increase of those following agricultural pursuits, there has been a tremendous increase in non-self-sustaining and non-productive persons. We now have millions engaged in such pursuits as advertising, salesmanship, social, welfare and relief work, public employees, debt-merchants and debt collectors, real estate operators, brokers, bookmakers, bootleggers, and many other forms and kinds of non-producing individuals, not to mention our high and increasing prison population. From the standpoint of producing the needs of the people, these groups might be considered as parasites upon the real producers. Of course, I do not mean to say that under present conditions some of these non-producers are not necessary, particularly the welfare, relief and social workers. If we are going to maintain poverty and millions of unemployed, we must have hundreds of thousands engaged in the task of keeping them from starving. Can we doubt that if all or most of these non-producers were engaged in productive enterprise, the working hours of all could be shortened? It is true that this great increase of non-producers has helped to raise the per cent of gainfully employed, but it has also placed additional burdens on the backs of the producers of real wealth.

One who has only the selfish viewpoint of the industrialists who set profits as their only goal, may be content to dismiss this great social problem of our day merely by saying that the per cent of gainfully employed has increased along with the use of machinery. But the statesman who has social vision cannot so easily blind himself to the fact that, notwithstanding this, we have some eleven million unemployed and that if we again reach even the 1929 level of production volumes, we shall still have some eight million unemployed in this country.

Then we also have four gasoline stations on one corner, many struggling individual merchants and like "rugged individualists" who are struggling to stay in futile "private enterprise" rather than to lend their efforts toward achieving the productive capacities that will supply the needs of the people. In other words, the real producers of wealth in the country are having more and more non-producers to support. In the face of obvious potential abundance on the one hand and widespread poverty and unemployment on the other hand, we maintain these great non-productive classes, because we think we want that rugged individualism and private enterprise which it was possible for our fathers and grandfathers to have a hundred years ago. While we struggle to maintain private enterprise by requiring small merchants and farmers to work from sun-up to long after sundown, and industrial workers to labor many more hours than should be necessary in a system which has so increased their productivity, we seem to overlook the fact that the great aim in life is not profits, but to live and to live the more abundant life which the Saviour of men laid down as the goal for human achievement, when He said:

"I am come that ye might have life, and that ye might have it more abundantly."

(Submitted by the Bureau of Agricultural Economics, Department of Agriculture)

INCOME OF HIRED LABORERS

With respect to other areas and crops than cotton, few of the studies that have been made are comparable, owing to variations with respect to home use products, perquisites, total family earnings, and total earnings throughout the year. However, taking the figures as they stand, the incomes of farm laborers in the various crop areas studied may be grouped as follows:

Area	Approximate earnings per year
1. Tobacco (Kentucky) 1935-36	\$188
2. Small grains (Kansas and Minnesota) 1935-36	206-254
3. Truck (New Jersey) 1938	265
4. Corn (Illinois and Iowa) 1935-36	308-312
5. Sugar beets (4 States) 1935	340
6. Hops (Washington) 1937:	
Single person	352
Family head	496
7. California 1935	261
1935-36	651

In the areas covered by Messrs. Folsom and Vasey in 1936, the average earnings were as follows:

1. Self-sufficing (Tennessee)	\$126
2. Cotton (Louisiana)	130
(Texas)	162
3. Tobacco (Kentucky)	188
4. Small grains (Minnesota)	206
(Kansas)	254
5. Stock ranch (Colorado)	285
6. Corn (Illinois)	308
(Iowa)	312
7. Dairy (Pennsylvania)	353
8. Fruit (California)	651

¹ Vasey and Folsom studies are averages of single hands and family groups; in some cases they include sharecroppers, tenants and farm owners who worked out as laborers; in some instances migratory and resident workers' incomes are represented in the averages.

² Income represents earnings for seasonal employment on the farm only. Average number of days available for farm work was approximately 99. Income figures are case averages including both single persons and families of workers.

EXHIBIT No. 2671

[Submitted by the Bureau of Agricultural Economics, Department of Agriculture]

TABLE B.—*Equities in farm real estate, by tenures, United States, 1930 and 1935 (Investments of farm operators and of other people)*

Tenure groups	Equity of the operator		Equity of others (Mortgage debt of the operator)		Operator had no ownership interest		Equity of all groups	
	1930	1935	1930	1935	1930	1935	1930	1935
	<i>Percent</i>	<i>Percent</i>	<i>Percent</i>	<i>Percent</i>	<i>Percent</i>	<i>Percent</i>	<i>Percent</i>	<i>Percent</i>
Farms operated by full owners.....	35.1	33.9	9.0	11.2	—	—	44.1	45.1
Farms operated by part owners.....	6.5	5.2	2.4	3.7	8.1	7.9	17.0	16.8
Manager farms.....	—	—	—	—	4.7	4.8	4.7	4.8
Tenant farms.....	—	—	—	—	34.2	33.3	34.2	33.3
All farms.....	41.6	39.1	11.4	14.9	47.0	46.0	100.0	100.0

The table above indicates by tenures the percentage of the total value of farm real estate belonging to various groups. The equity of operators in all farms in 1935 equalled 39.1 percent of the total value as compared with 41.6 percent in 1930. This decline represents primarily an increase in the ratio of debt to value, the percentage of the total value mortgaged by the operator increasing from 11.4 percent in 1930 to 14.9 percent in 1935. Even though debt was declining, values were falling much more rapidly during that period. Farms in which the operator had no ownership interest were 46 percent of the total value in 1935 as against 47 percent in 1930. While available data indicates that the number of farm tenants increased during the same period, the value of tenant farms represented a smaller percentage of total farm real estate values, and the percentage of all farmers who were tenants decreased.

COOPERATIVE PART-TIME DIVERSIFIED OCCUPATIONS PROGRAM ¹

C. E. Rakestraw, Federal Agent, Industrial Education

It was a typical May-day high school graduation in a small community in one of the southern states. On that day some twenty boys received their high school diplomas. The Superintendent of Schools, whom we shall call Mr. Smith, wondered just what would become of these boys since he knew that only five would have the financial opportunity to go to college. The other fifteen would have to secure employment in the community or elsewhere in the state or country. Mr. Smith also knew that the education which these boys had received did not prepare them for employment in any special field of work. All that he could hope was that their high school education would afford a sufficient background to permit them to succeed in learning any occupation in which they might become engaged. The tragedy he knew lay in the fact that not one of the boys had had sufficient counseling and occupational information to enable him to make an intelligent choice of a life work. Mr. Smith, with this problem weighing heavily on his mind, sought advice from his local school board and the vocational division of the state department of education. Representatives of the state department of vocational education, with one from the United States Office of Education, conferred with him regarding the boys. All were agreed that the solution of the problem would be to provide some form of vocational training for the youth of the community before sending him out into the work-a-day world.

Of course, it was out of the question for Mr. Smith's community to provide a vocational school manned and equipped to teach more than one or two occupations. Even the cost of this small effort would be prohibitive. The representatives of the state department of vocational education stressed the fact that all programs should be closely adapted to the social and economic needs of the community, employers, and employees. With this in mind a study was made of local employment opportunities in the community, and then Mr. Smith and his school board established a program, based on a plan which is known as the Cooperative Part-Time Program in Diversified Occupations.

WHAT IS THE PROGRAM?

Briefly stated, the Cooperative Part-Time Diversified Occupations Program operates as follows: High school students of employable age are enrolled in the program and spend one-half of each school day in bona fide employment in their chosen trades or occupations for the purpose of securing organized instruction on the job as student-learners. Two periods of the remaining one-half day of the high school time are devoted to directed and supervised study of technical and related subjects pertinent to the trades or occupations in which the students are engaged. The technical subjects, which are studied on an individual basis, are those subjects which have been approved by a craft or occupational committee as being pertinent. Related subjects are those which are taught on a group basis and include such social subjects as economics, civics, health, safety. Stress is also placed upon the development of good work habits and attitudes. The remaining school time is devoted to the study of regular academic subjects. The pupils included in this type of program are usually high school juniors and seniors, although boys and girls of sixteen years of age and over who can profit from the training are not excluded.

REQUIRED CREDITS

Those who wish to do so may graduate from high school with a regular diploma which will permit college entrance. To do this, however, it is necessary for the student upon entering high school to arrange his subjects in such a manner as to gain eight required credits during the first two years. The remaining required two credits plus six electives may be earned during the junior and senior years. Credit is allowed on a vocational basis for time spent in employment and time devoted to the study of technical and related subjects. Since high school credit

requirements vary in the various states, the above statement cannot be applied to all; and space will not permit describing the various plans for allowing credits.

Cooperative Part-Time Diversified Occupational training has grown from a few programs in 1934 to some six hundred at the close of the last school year. Each of the states in the Southern Region now has programs of this type, varying in number from five to thirty, with an approximate total enrollment of 5,000.

STANDARDS SET

The State Supervisors of Trade and Industrial Education in the Southern Region, realizing that all programs of vocational training should be organized on a sound basis, adopted the following standards for Cooperative Part-Time Programs in Diversified Occupations at their regional conference in Little Rock, Arkansas, in April, 1939:

Field Training.—Any trade, industrial, distributive, commercial, or service occupation eligible for inclusion in the training program for student-learners shall be one the preparation for which requires 2,000 hours, or more, of organized instruction and organized work experience on the job, as determined by an occupational committee.³

Agreement.—A written training agreement or memorandum shall be required for each student and shall include a schedule of processes to be learned on the job, related instruction to be given in school, wages and length of training period, type and degree of responsibility of parties concerned, provision for school credit, hours of work and related instruction, provision for job progression, probationary period and termination of agreement.

Representative Advisory Committees.—(1) State: The program of training shall be conducted under the general oversight of a representative state advisory committee, such committee to consist of equal representation from employers and labor, together with a representative of the state department of education.

(2) Local: The program of training shall be conducted under the general oversight of a representative local advisory committee, such committee to consist of equal representation from employers and labor, together with a representative of the local department of education.

(3) Craft or occupational committees shall be formed for the purpose of assisting the coordinators in developing the schedules of processes, approving outlines of related instruction, and assisting in organizing the individual student's training plan for a particular occupation. Such a committee may be composed of one or more members of each craft or occupation.

Rates of Pay.—Provisions shall be made for a progressively increasing scale of wages on an hourly basis over the period of training, which should average approximately 50 percent of that paid a regular worker.

Hours of Work and Study.—All student-learners shall be required to spend one-half of the regular school day, which shall be not less than fifteen hours per week (three consecutive clock hours per day), in organized work experiences on the job under the joint supervision of the school and the employer. In addition to the required time spent in acquiring job experience, each student-learner shall devote, each day, two of the regular school periods to the study of technical and related subject matter on a correlated basis, under a qualified coordinator-instructor or a qualified related-subjects teacher, in segregated classes.

Selection of Student-Learners.—Student-learners shall be enrolled in this program with the approval of the local advisory committee on the basis of their ability to profit from the training and only after they have received advisement and guidance from trained coordinators or counselors.

Schedule of Processes.—The schedule of processes to be learned on the job and the related subject content to be taught each student-learner in school shall be outlined and approved by representative occupational or craft committees.

Equipment and Instructional Materials.—The local school authorities shall provide adequate funds to secure necessary equipment and instructional materials, including reference material, textbooks, bulletins, pamphlets, trade journals, correspondence courses, etc., to insure that pertinent, practical, and current occupational practices may be taught in the two school periods per day devoted to technical and related study.

High School Credit.—Provision shall be made by state and local school authorities to enable the student-learners to receive high school credit for the satisfactory

³ By student-learner is meant a student enrolled in a public high school who has satisfactorily completed at least eight units of credit toward graduation, or equivalent, is at least 16 years of age, and has been accepted for occupational training on a cooperative basis under a written agreement, approved by a representative advisory committee, among the school, employer, student, and parent.

completion of the schedule of organized work experiences and related instruction, making high school graduation possible. (Such an arrangement has been made and accepted by the Southern States and approved by the Southern Association of Colleges and Secondary Schools.)

Ratio of Student-Learners.—Due consideration will be given to the ratio of student-learners to regularly employed workers in any occupational field, and shall be determined by the local advisory committee.

Job Progression.—Provision will be made for the student-learners to be transferred from one job process to another upon reaching the proficiency level required for satisfactory performance in the occupation.

Placement and Follow-up.—Consideration will be given to final placement and follow-up, and in cases of occupations requiring more time for training than can be given during the period the student is enrolled in high school, arrangements for the completion of training on a full-time basis will be made in cooperation with the Federal Committee on Apprenticeship.

That such a program as the cooperative part-time diversified occupational training is needed is shown by the following facts: There are enrolled in the public high schools throughout the country approximately 6,500,000 students. The traditional high school course is designed largely to prepare students for college entrance. Since only a small percentage of the graduates enter college, it became apparent many years ago that some form of vocational training should be provided in the public school system. In the larger industrial communities vocational schools have been organized to provide such training for the boys and girls residing there. But vocational schools are expensive to build, equip, and maintain, and many communities cannot offer any such advantages for their youth. The only program possible for these small communities to organize is the cooperative part-time type which, in reality, uses the equipment in the business and industrial establishments of the community as a laboratory. This plan does not in any sense supplant the regular apprentice-training program, but, as has been shown in many communities, actually stimulates the development of apprenticeship.

That the Cooperative Part-Time Diversified Occupations Program proved successful from the first is indicated from the fact that 36 percent of the first graduating class in one of the first communities to establish this program continued in permanent employment with the business or industrial establishment where training was received, 32 percent received employment in other business or industrial establishments in the occupations for which their training had prepared them, and the remainder of the group, although not receiving immediate employment, could state that, in addition to their high school diploma, they had acquired 2,000 hours of practical working experience in a definite trade or occupation.

Employers in the communities where these programs have been organized have accepted the responsibility of cooperating with the schools from the standpoint of their duty, as citizens, to provide an opportunity for youth to prepare for useful employment. A study of the employment records of graduates indicates that the employers have provided continued employment for these students without displacement of regular workers. In other words, many are retained after they finish their course because they have made themselves valuable to the employer and not because the employer feels the need of additional workers. The local authorities and the coordinators have been urged not to seek placement of students in any occupation where so doing would mean displacement of regular workers. However, since it is necessary for the student-learner to receive work experiences in accordance with the approved schedule of processes, it is not possible for him to replace a regular worker in any phase of an occupation and at the same time achieve the objectives of the training. The employees and labor groups have accepted the program on the same basis, realizing also that in such a program the danger of training more workers than the occupations can absorb is eliminated. School authorities have accepted the program enthusiastically because it provides a means of offering to their students occupational training which could not otherwise be provided in their communities.

COOPERATIVE PART-TIME DIVERSIFIED OCCUPATIONS PROGRAM¹

C. E. Rakestraw, Federal Agent, Industrial Education

It was a typical May-day high school graduation in a small community in one of the southern states. On that day some twenty boys received their high school diplomas. The Superintendent of Schools, whom we shall call Mr. Smith, wondered just what would become of these boys since he knew that only five would have the financial opportunity to go to college. The other fifteen would have to secure employment in the community or elsewhere in the state or country. Mr. Smith also knew that the education which these boys had received did not prepare them for employment in any special field of work. All that he could hope was that their high school education would afford a sufficient background to permit them to succeed in learning any occupation in which they might become engaged. The tragedy he knew lay in the fact that not one of the boys had had sufficient counseling and occupational information to enable him to make an intelligent choice of a life work. Mr. Smith, with this problem weighing heavily on his mind, sought advice from his local school board and the vocational division of the state department of education. Representatives of the state department of vocational education, with one from the United States Office of Education, conferred with him regarding the boys. All were agreed that the solution of the problem would be to provide some form of vocational training for the youth of the community before sending them out into the work-a-day world.

Of course, it was out of the question for Mr. Smith's community to provide a vocational school manned and equipped to teach more than one or two occupations. Even the cost of this small effort would be prohibitive. The representatives of the state department of vocational education stressed the fact that all programs should be closely adapted to the social and economic needs of the community, employers, and employees. With this in mind a study was made of local employment opportunities in the community, and then Mr. Smith and his school board established a program, based on a plan which is known as the Cooperative Part-Time Program in Diversified Occupations.

WHAT IS THE PROGRAM?

Briefly stated, the Cooperative Part-Time Diversified Occupations Program operates as follows: High school students of employable age are enrolled in the program and spend one-half of each school day in bona fide employment in their chosen trades or occupations for the purpose of securing organized instruction on the job as student-learners. Two periods of the remaining one-half day of the high school time are devoted to directed and supervised study of technical and related subjects pertinent to the trades or occupations in which the students are engaged. The technical subjects, which are studied on an individual basis, are those subjects which have been approved by a craft or occupational committee as being pertinent. Related subjects are those which are taught on a group basis and include such social subjects as economics, civics, health, safety. Stress is also placed upon the development of good work habits and attitudes. The remaining school time is devoted to the study of regular academic subjects. The pupils included in this type of program are usually high school juniors and seniors, although boys and girls of sixteen years of age and over who can profit from the training are not excluded.

REQUIRED CREDITS

Those who wish to do so may graduate from high school with a regular diploma which will permit college entrance. To do this, however, it is necessary for the student upon entering high school to arrange his subjects in such a manner as to gain eight required credits during the first two years. The remaining required two credits plus six electives may be earned during the junior and senior years. Credit is allowed on a vocational basis for time spent in employment and time devoted to the study of technical and related subjects. Since high school credit requirements vary in the various states, the above statement cannot be applied to all; and space will not permit describing the various plans for allowing credits.

Cooperative Part-Time Diversified Occupational training has grown from a few programs in 1934 to some six hundred at the close of the last school year. Each of the states in the Southern Region now has programs of this type, varying in number from five to thirty, with an approximate total enrollment of 5,000.

STANDARDS SET

The State Supervisors of Trade and Industrial Education in the Southern Region, realizing that all programs of vocational training should be organized on a sound basis, adopted the following standards for Cooperative Part-Time Programs in Diversified Occupations at their regional conference Little Rock, Arkansas, in April, 1939:

Field Training.—Any trade, industrial, distributive, commercial, or service occupation eligible for inclusion in the training program for student-learners shall be one the preparation for which requires 2,000 hours, or more, of organized instruction and organized work experience on the job, as determined by an occupational committee.¹

Agreement.—A written training agreement or memorandum shall be required for each student and shall include a schedule of processes to be learned on the job, related instruction to be given in school, wages and length of training period, type and degree of responsibility of parties concerned, provision for school credit, hours of work and related instruction, provision for job progression, probationary period, and termination of agreement.

Representative Advisory Committees.—(1) State: The program of training shall be conducted under the general oversight of a representative state advisory committee, such committee to consist of equal representation from employers and labor, together with a representative of the state department of education.

(2) Local: The program of training shall be conducted under the general oversight of a representative local advisory committee, such committee to consist of equal representation from employers and labor, together with a representative of the local department of education.

(3) Craft or occupational committees shall be formed for the purpose of assisting the coordinators in developing the schedules of processes, approving outlines of related instruction, and assisting in organizing the individual student's training plan for a particular occupation. Such a committee may be composed of one or more members of each craft or occupation.

Rates of Pay.—Provisions shall be made for a progressively increasing scale of wages on an hourly basis over the period of training, which should average approximately 50 percent of that paid a regular worker.

Hours of Work and Study.—All student-learners shall be required to spend one-half of the regular school day, which shall be not less than fifteen hours per week (three consecutive clock hours per day), in organized work experiences on the job under the joint supervision of the school and the employer. In addition to the required time spent in acquiring job experience, each student-learner shall devote each day, two of the regular school periods to the study of technical and related subject matter on a correlated basis, under a qualified coordinator-instructor or a qualified related-subjects teacher, in segregated classes.

Selection of Student-Learners.—Student-learners shall be enrolled in this program with the approval of the local advisory committee on the basis of their ability to profit from the training and only after they have received advisement and guidance from trained coordinators or counselors.

Schedule of Processes.—The schedule of processes to be learned on the job and the related subject content to be taught each student-learner in school shall be outlined and approved by representative occupational or craft committees.

Equipment and Instructional Materials.—The local school authorities shall provide adequate funds to secure necessary equipment and instructional materials, including reference material, textbooks, bulletins, pamphlets, trade journals, correspondence courses, etc., to insure that pertinent, practical, and current occupational practices may be taught in the two school periods per day devoted to technical and related study.

High School Credit.—Provision shall be made by state and local school authorities to enable the student-learners to receive high school credit for the satisfactory completion of the schedule of organized work experiences and related instruction,

¹ By student-learner is meant a student enrolled in a public high school who has satisfactorily completed at least eight units of credit toward graduation, or equivalent, is at least 16 years of age, and has been accepted for occupational training on a cooperative basis under a written agreement, approved by a representative advisory committee, among the school, employer, student, and parent.

making high school graduation possible. (Such an arrangement has been made and accepted by the Southern States and approved by the Southern Association of Colleges and Secondary Schools.)

Ratio of Student-Learners.—Due consideration will be given to the ratio of student-learners to regularly employed workers in any occupational field, and shall be determined by the local advisory committee.

Job Progression.—Provision will be made for the student-learners to be transferred from one job process to another upon reaching the proficiency level required for satisfactory performance in the occupation.

Placement and Follow-up.—Consideration will be given to final placement and follow-up, and in cases of occupations requiring more time for training than can be given during the period the student is enrolled in high school, arrangements for the completion of training on a full-time basis will be made in cooperation with the Federal Committee on Apprenticeship.

That such a program as the Cooperative Part-Time Diversified Occupational Training is needed is shown by the following facts: There are enrolled in the public high schools throughout the country approximately 6,500,000 students. The traditional high school course is designed largely to prepare students for college entrance. Since only a small percentage of the graduates enter college, it became apparent many years ago that some form of vocational training should be provided in the public school system. In the larger industrial communities vocational schools have been organized to provide such training for the boys and girls residing there. But vocational schools are expensive to build, equip, and maintain, and many communities cannot offer any such advantages for their youth. The only program possible for these small communities to organize is the cooperative part-time type which, in reality, uses the equipment in the business and industrial establishments of the community as a laboratory. This plan does not in any sense supplant the regular apprentice-training program, but, as has been shown in many communities, actually stimulates the development of apprenticeship.

That the Cooperative Part-Time Diversified Occupations Program proved successful from the first is indicated from the fact that 36 percent of the first graduating class in one of the first communities to establish this program continued in permanent employment with the business or industrial establishment where training was received, 32 percent received employment in other business or industrial establishments in the occupations for which their training had prepared them, and the remainder of the group, although not receiving immediate employment, could state that, in addition to their high school diploma, they had acquired 2,000 hours of practical working experience in a definite trade or occupation.

Employers in the communities where these programs have been organized have accepted the responsibility of cooperating with the schools from the standpoint of their duty, as citizens, to provide an opportunity for youth to prepare for useful employment. A study of the employment records of graduates indicates that the employers have provided continued employment for these students without displacement of regular workers. In other words, many are retained after they finish their course because they have made themselves valuable to the employer and not because the employer feels the need of additional workers. The local authorities and the coordinators have been urged not to seek placement of students in any occupation where so doing would mean displacement of regular workers. However, since it is necessary for the student-learner to receive work experiences in accordance with the approved schedule of processes, it is not possible for him to replace a regular worker in any phase of an occupation and at the same time achieve the objectives of the training. The employees and labor groups have accepted the program on the same basis, realizing also that in such a program the danger of training more workers than the occupations can absorb is eliminated. School authorities have accepted the program enthusiastically because it provides a means of offering to their students occupational training which could not otherwise be provided in their communities.

CONCENTRATION OF ECONOMIC POWER.

EXAMPLE OF A UNIT ON BUSINESS CYCLES

"The American People Have Tried To Evolve an Economic System Which Provides the Greatest Good for the Greatest Number." Unit II. Eleventh Grade Social Studies. Benjamin Franklin High School, Rochester, N. Y. Problem 6, p. 37-39. (Mimeo.)

The business cycle is the topic of Problem 6. The following material is included:

A. Economic Ideas and Terms You Should Know:

Business cycle

Difference between "panic" and "depression"

Theories regarding the causes of this cycle

The use of index number to measure the cycle

The stages of a "normal" cycle.

B. Guide Posts:

Although the business cycle seems to operate in accordance to certain "laws" it must be remembered that these are not "natural laws," but are laws brought about by man-made conditions.

It seems certain that the business cycle operates only as it does because society previously establishes, or fails to remove, certain conditions which bring it about.

Therefore, depressions may be called "man made." This seems to indicate that they can be "man controlled."

¹ Supplement to Statement, "Education and Economic Literacy," by William G. Carr, presented before the Temporary National Economic Committee, April 25, 1940.

CONCENTRATION OF ECONOMIC POWER 17505

One must always distinguish between two conditions which have similar outward appearances; namely, "overproduction" and "underconsumption."

Depressions are apparently a symptom of an ill in the "social body." To prevent depressions something must be done, but this requires some modification of economic conditions as they now are.

A modification of capitalism does not necessarily mean a change to socialism or communism.

EXAMPLE OF A UNIT ON REGULATION OF INDUSTRY

"The Development of the United States after the Civil War."
11B History (Special). Guide Sheet 1. South Philadelphia
High School for Girls, Philadelphia, Pa. (Mimeo.)

Part III of the outline for this history class is headed, "The Growth of Big Business and Consequent Attempts at Regulation." The topics included are shown below:

- A. List the reasons for the prosperity of the North during the Civil War.
- B. Describe the economic rebuilding of the South after the Civil War.
- C. The Consolidation of Industry:
 1. Causes.
 2. Extent of consolidation.
 3. Types.
 4. The disadvantages and advantages.
- D. Governmental Regulation of Big Business:
 1. The railroads.
 - a. Why was regulation desired?
 - b. Types:
 - (1) Evaluate attempts at State regulation.
 - (2) Chart all the Federal Acts regulating the railroads, giving names of act; date; terms; importance; attitude of courts (if expressed).
 2. Big Business:
 - a. Review the disadvantages of big business to determine the causes for regulation.
 - b. Chart the laws regulating big business as you charted railroad regulations.
 - c. What new ideas of regulation have been developed in the present administration?

EXAMPLE OF A UNIT ON AGRICULTURE

"Adjusting Agricultural Life to Meet the Conditions Created by the Power Age." Section II. *Materials of Instruction Suggested for the Second Year of the Core Curriculum of Virginia Secondary Schools*. Richmond, Va.: State Board of Education, October 1938. p. 75. (Mimeo.)

The following outline is suggested for discussion of the farm tenancy question:

Combating the Evils of Farm Tenancy

Suggested Content

- I. Contributing causes to share-cropping and other forms of farm tenancy:
 - A. The difficulty experienced by many farmers in retaining possession or operating a farm successfully due to:
 1. Original failure to recognize the necessity of providing public education.
 2. Original unequal distribution of land.
 3. The relatively small income from farming.
 4. The relative insecurity of farm returns.
 5. The relatively high cost of production.
 6. Lack of crops suitable to soil areas.
 7. Tendency to engage in single-crop farming.
 - B. Concentration of land and capital in the hands of a few.

- II. Concomitants of tenancy:
- A. Economic insecurity of most tenants.
 - B. Unsatisfactory standards of living.
 - C. Impoverishment of soil.
 - D. Inefficient farming practice.
 - E. Transient farm population.
 - F. Maladjustments of personality:
 1. Apathy.
 2. Servility.
 - G. Non-participation in civic life.
 - H. Large families.
- III. Aids that may help in combating the evils of tenancy:
- A. More education.
 - B. Government subsidy.
 - C. Improved tenant-owner relationships.
 - D. Attraction of the more capable to the farm.
 - E. Application of scientific research.
 - F. Growing crops suitable to the soil and climate.

EXAMPLE OF A UNIT IN CONSERVATION

Summary of a ninth grade project. Memorandum from Hazel Sample, Norris School, Norris, Tenn. January 31, 1939. 3 p. (Mimeo.) Also 3-page typewritten statement entitled: "Ninth Grade Report-Section B."

Excerpts from the memorandum on the selection and development of the topic, "Game Conservation," follow:

"After due consideration the class selected the topic of Game Conservation and proceeded to make specific plans for the work. So far, there have been three steps to this unit: The first step was the preparation of charts giving all the necessary information concerning cover, food, habitat, predators, range and present supply of animals, fish and game birds of this area * * *

"The purpose of the next step of the unit was to find out what agencies, Government or private, are connected with the work of conservation and what they have done and are doing * * * Various committees in the group worked on the following topics as set up by the class: the history of conservation, the government agencies that deal with conservation, the government projects, such as C. C. C., T. V. A., Boulder Dam, United States Bureau of Fisheries, and National Forests and Parks * * *

"The third step in the unit was the practical one of actually taking part in a project for game conservation. For the use of this class, Mr. Varnell by recommendation of the Forestry Department secured the allotment of one hundred acres of land for school use by this group and others which may follow. Members of this class have done a good practical job of surveying and staking this section of land * * * The class has also divided the strip of land into five units so that each of the five committees of the class will have the full responsibility of planning and executing the improvements to the land in the light of their purpose of taking part in all the activities which go into providing a game refuge * * *

From the typewritten report comes the following supplementary information:

"Type of activities done on the plot: planting of game food, identification of game food, reforestation, erosion work, thinning of trees, rabbit retreats, clearing of fire lanes, clearing of debris from two old dwellings, grafting of fruit and nut trees, identification of wild flowers and their conservation, making of propagation beds, correct method of pressing and mounting wild flower specimens, and the possibility of pasturing certain sections advantageously."

EXAMPLE OF A UNIT ON TRANSPORTATION PROBLEMS

"American Economic Life." Benjamin Franklin High School, New York, N. Y. p. 15-16. (Mimeo.)

The problems of transportation and communication are taken up in Section F of this unit, in the part entitled, "The United States without a Frontier 1890 * * *." The outline follows:

- A. Railroads:
1. Consolidation into great systems.
 2. Expansion of the powers of the Interstate Commerce Commission:
 - a. Hepburn Act.

- b. Mann-Elkins Act.
- c. Esch-Cummings Act—1920.
- 3. Elements of strength and weakness in the present economic position of railroads:
 - a. Competing means of transportation.
 - b. Debt burden.
 - c. Increasing efficiency.
 - d. Government aid.
 - e. New policy toward consolidation.
- 4. Shall the United States government own and operate the railroads?
- B. Automobile and its influence:
 - 1. on the railroad.
 - 2. on road building.
 - 3. on rural life.
 - 4. on problem of Federal regulation of automobile traffic.
- C. Water transportation:
 - 1. Development of internal water transportation.
 - 2. Panama Canal.
 - 3. Proposed St. Lawrence Canal.
 - 4. Merchant marine:
 - a. continued decline to 1914.
 - b. effect of World War.
 - c. attempts to preserve World War gains.
 - d. value of merchant marine.
- D. Air Transport.
- E. Post office—its expanding activities.
- F. Radio:
 - 1. a factor in American economic life.
 - 2. problem of control—Federal Communication Commission.

EXAMPLE OF A UNIT ON PUBLIC UTILITIES

"Exchanging Products." Nine A, Social Studies. Unit III. Tentative Outline. Cleveland, Ohio: Department of Social Studies, Cleveland Public Schools. September 8, 1936. p. 67-68. (Mimeo.)

In part III, which pertains to the relations between business and government, government aids to business and government restraint of business are discussed. Public utilities and public control are included in section C, having to do with restraint of business, as follows:

Government Restraint of Business

- 1. Laissez-faire.
- 2. Government control or regulation:
 - a. Zoning.
 - b. Bank inspection.
 - c. Pure food laws.
 - d. Blue sky laws.
 - e. Others.
- 3. Control of public utilities:
 - a. Reasons for control:
 - (1) Vital service rendered by utilities.
 - (2) Supposed to be available to everybody on equal terms.
 - (3) Can operate only by special authority of government.
 - b. Provisions for control:
 - (1) Interstate Commerce Act, 1887.
 - (2) State Utilities Commissions.
 - (3) Federal Trade Commission.
 - (4) New Deal legislation—T. V. A., Holding Company Act, etc.
 - (5) Others.
- 4. Anti-trust laws:
 - a. Sherman Anti-Trust Act.
 - b. Clayton Anti-Trust Act.
 - c. Federal Trade Commission Act.
 - d. Recent government action.

EXAMPLE OF A UNIT ON LABOR RELATIONS

"Employer and Employee." Modern Problems Unit No. 7. Grade 12. Cleveland, Ohio: Board of Education, Division of Social Studies, October 1938. p. 11-12. (Mimeo.)

Topic VI of this unit is entitled "What Causes Strikes? How Can Strikes Be Settled?" The following outline is suggested:

1. Causes of strikes.
2. When strikes occur:
 - a. Principal industries involved.
 - b. Comparison in periods of depression and prosperity.
3. Types of strikes:
 - a. "Sit-down."
 - b. General.
 - c. Sympathetic.
4. Strike tactics:
 - a. Use of violence.
 - b. Picketing.
 - c. Attitude toward "scabs."
5. Employer tactics:
 - a. Use of strikebreakers.
 - b. Use of company guards.
 - c. Appeal to state for National Guard.
 - d. Appeal to courts.
6. Cost of strikes:
 - a. To the workers.
 - b. To the employer.
 - c. To the public.
7. Possible methods of settling labor disputes:
 - a. Conciliation.
 - b. Mediation.
 - c. Arbitration.
 - d. Laws preventing strikes.

EXAMPLE OF A UNIT IN LABOR RELATIONS

"Labor in America." (For use in B11 American Life and Institutions.) Los Angeles, Calif.: City School District, Division of Instruction and Curriculum, Secondary Curriculum Section, November 1938. p. 16-17. (Mimeo.)

Section B of the subject matter outline for the course "Labor in America" deals with the rise of the problem of capital vs. labor. Organizations of labor are discussed within this section, as follows:

Organizations of Labor

- A. Labor unions:
 1. History—legality—Knights of Labor, etc.
 2. Two chief labor unions today.
 - a. A. F. of L., Gompers, Green.
 - b. C. I. O., John L. Lewis, Martin, Beck.
 3. Methods:
 - a. Collective bargaining.
 - b. Strike—walkout—sit down.
- B. Company unions:
 1. Purpose—to keep workers satisfied.
 2. Methods:
 - a. Profit sharing.
 - b. Compensation—unemployment.
 - c. Pension plans.

EXAMPLE OF A UNIT ON INCOME DISTRIBUTION

"Proposed Means of Bringing about a Better Distribution of Wealth." Unit III. Curriculum Record 1938-39. Grade 12. P. K. Yonge Laboratory School, Gainesville, Florida. (Mimeo.)

The following is part of the outline worked out for the unit on the distribution of wealth:

- A. Meaning of wealth:
 1. Social wealth vs. individual wealth.
 2. Meaning of money and its functions.
- B. The wealth of the United States:
 1. Raw materials:
 - a. Agricultural land.
 - b. Minerals unmined, estimated.
 - c. Forest lands still standing.
 2. Manufacturing plants for:
 - a. Food production.
 - b. Textile and clothing production.
 - c. Automobile and tire production.
 - d. Paper making, printing and publishing.
 - e. Iron and steel.
 - f. Other manufactures.
 3. Services:
 - a. Electric power utilities facilities.
 - b. Transportation facilities.
 - c. Merchandising stores.
 - d. Money and credit establishments.
 - e. Labor—number of workers, estimated value in production.
- C. Distribution and use of wealth in United States:
 1. Growth of total income.
 2. Sources of total income (use same division as in listing producing agencies).
 3. Geographical distribution of wealth.
 4. Family division of national income.
 - a. Per capita division.
 5. Distribution of income by size of income per person.
- D. Means of increasing wealth and effecting a better distribution:
 1. Application of science and invention to means of production.
 2. Increase of plant facilities.
 3. Improvement of distributive system of commodities.
 4. Increase wealth of lower income groups:
 - a. Lower prices.
 - b. Higher wages.
 - c. Income tax on upper groups.
 - d. Economic security for lower group in old age.

EXAMPLE OF A UNIT ON INCOME DISTRIBUTION

"Current Economic Problems." Grade 12. South Pasadena High School, South Pasadena, California. p. 15-17. (Mimeo.)

Among the units of this course is Unit V, entitled, "Where the Return from Production Goes." The outline of this unit follows:

Problems of the Unit

1. What is distribution? How is distribution related to income?
 - a. How could the income of the average American family be increased?
 - b. How do progressive taxes affect distribution?
 - c. Why do we have poverty?
2. How is distribution related to production?
 - a. What is the enterpriser's responsibility relative to distribution?
 - b. Do we have an "economy of abundance" in the U. S.? Explain.
3. How is the amount of rent agricultural land will return determined? urban land?
 - a. Why is the farmer's distribution problem so serious? How has government sought to aid the farmer?
 - b. How has cooperative marketing aided California growers?
4. Do those who supply the capital for industry obtain a fair return?
 - a. Why is interest paid for loans?
 - b. How are interest rates determined?
 - c. How is saving motivated?

5. What is the place of the business man in industry?
 - a. Is the business man fairly rewarded for his services? Why doesn't labor carry the risks of business? Would you choose business as a career? Why or why not?
 - b. What are the sources of profits from which the income of management is drawn? How does competition affect profits?
6. How is government paid for its services to business and industry?
 - a. Is government overpaid?
7. How is the share of income going to labor determined?
 - a. How are wage rates determined? How do money wages and real wages differ?
 - b. What is a fair wage? How may the efficiency of labor be increased?
 - c. What is collective bargaining? How does it work?
 - d. How do industrial unions differ from craft unions?
 - e. Should labor be allowed to strike?
 - f. Should labor unions be compelled to incorporate? Why is the public vitally concerned in capital labor conflicts?
 - g. Should the Wagner Act be modified?
 - h. How do you think labor disputes should be settled?

EXAMPLE OF A UNIT ON SOCIAL SECURITY

"Social Security." Modern Problems Unit No. 9. Grade 12. Cleveland, Ohio: Board of Education, Division of Social Studies, September 1939. p. 4-5. (Mimeo.)

Topic I suggested in this study of social security is "Need for Social Security." The outlined proposed follows:

1. Relief prior to 1933:
 - a. Local poor relief.
 - b. State action on relief.
2. Break-down of the local relief system:
 - a. Economic changes.
 - b. Reasons for breakdown of local relief.
 - c. Federal action in 1932 on relief.
3. Relief under F. E. R. A. and C. W. A.:
 - a. Diversity of relief problems.
 - b. Nature of work relief.
 - c. The Civil Works Program.
 - d. Direct relief before 1935.
 - e. Funds appropriated to these agencies.
4. Permanence of the relief problem:
 - a. Probable permanence of destitution.
 - b. Our economic instability.
 - c. Seasonal variations in employment.
 - d. Technological improvement and unemployment.
 - e. Increase in the number of aged in the United States.
5. Some other plans proposed to bring about Social Security:
 - a. The "Share-our-Wealth" movement.
 - b. The Townsend Old-Age Pension Plan.
 - c. The National Union for Social Justice.

EXAMPLE OF A UNIT IN CONSUMER PROTECTION AND EDUCATION

"Social Problems." Senior course. Eugene High School, Eugene, Oregon. (Mimeo.)

As part of the Social Problems course, pupils take up the problems of the consumer. Section A and the first part of Section B are quoted from the suggested study and discussion problems on consumer exploitation and the cooperative movement:

- A. *Statement of the Main Problem:* How can the consumer be protected from exploitation?
 1. Who is the Consumer?
 2. What is exploitation?
 3. What is consumer exploitation?
- B. *Analysis of the Problem:*
 1. Where is the problem of consumer exploitation located?
 2. When did the problem start?

3. How serious is the problem? To what extent does each of the following contribute to the seriousness of the problem:
- a. The changing nature of human wants?
 - b. False and misleading advertisements and testimonials?
 - c. Inability of consumers to judge quality of goods?
 - d. Wide price variations for the same or similar quality. (Dumping)?
 - e. Confusion of labels and brands?
 - f. Short weights: Honest versus intentional errors?
 - g. Intentionally cheapened quality of products?
 - h. Artificial scarcity and planned destruction?
 - i. Needless wastes of depressions, unemployment, duplication, cut-throat competition, swift changes in style, etc.
 - j. Increased price of product far beyond that which wage cost increases justify?
 - k. Low incomes and inadequate levels of living?
 - l. Inadequate pure food and drug laws?
 - m. Indifference to Consumer Welfare?
 - n. Exploitation by middlemen?

EXAMPLE OF A UNIT ON CONSUMER PROTECTION AND EDUCATION

"Consumer Education." Sacramento High School, Sacramento, Calif. p. 32-33. (Mimeo.)

In division III on the improvement of buying, Unit III pertains to protection and aid for consumer by law and other organizations. The following outline is offered for the study of federal control:

Problems and Suggested Procedure

Content

PROBLEM I

Some legislation has been enacted for the purpose of protecting the consumer-buyer against misrepresentation.

What are the federal laws protecting the consumer?

PROCEDURE

1. Explain the control exercised by the Federal Trade Commission.
2. Examine the Commission's Annual Report.
3. Discuss the labeling of furs prior to the rules set and adopted by the fur industry at the suggestion and force of the Federal Trade Commission.
4. What are the present rules for labeling of furs?
5. What trade practice was adopted in the knit underwear industry in 1930 due to the Commission?
6. Discuss other instances of control exercised by the Commission for the advantage of the consumer.
7. What new powers have been granted the Federal Trade Commission under the Wheeler-Lea Bill?
8. Discuss the Commission's present ruling regarding "rayon" labeling.
9. Review the Federal Food and Drug Act as studied in the unit on labels.

1. FEDERAL CONTROL

- a. Federal Trade Commission:
 1. Issues orders to "cease and desist" questionable business practices.
 2. Practices include adulteration, misleading as to quality, origin, weight and composition.
 3. Limitations of the powers of the Commission to protect the consumer.
 4. Penalties.
- b. Federal Food and Drug Act:
 1. A mislabeling act.
 2. Punishes attempt to mislead and deceive the purchaser through the statements or devices that appear on the label.
 3. Sets up relatively few positive requirements as to what information must be given.
 4. Operates primarily to protect the consumer's pocketbook, and only to an uncertain and limited degree as a protection to health.

*Problems and Suggested Procedure**Content*

PROCEDURE

10. Ask the students to look for the purple stamp, "U. S. Inspected and Passed," on meat purchased for the home. Discuss the purpose of such control. What events prior to the enactment of this legislation brought about this need?
11. Discuss the advantages to our business system of uniformity in weights and measures. Mention some new weights and measures adopted after exhaustive research work has been done such as the measurement of electricity, radium, light, radio, etc.
12. Read "Weighed and Found Wanting" by R. Littell, *Reader's Digest*, March 1938.

1. FEDERAL CONTROL

5. Limitations of the act give no control over advertising of foods and medicines either in the press, billboards, poster or radio.
6. Many loopholes in which the manufacturer is able to evade control, such as the distinctive name clause "misleading and fraudulent," etc.
- c. Federal and State Meat Inspection:
 1. Inspect at slaughtering and meat packing establishments.
 2. Meat found unsound, unhealthful, unwholesome is rejected and cannot be sold as food.
- d. Regulations of weights and measures:
 1. Standard weights and measures uniform throughout U. S.
 2. Bureau of Standards created in 1901 to take over the work of the office of weights and measures.
 3. Investigation, education and research carried on in problems of measurement.

EXAMPLE OF A UNIT ON MONEY—CONTROL AND ISSUANCE

"The American People Have Tried To Evolve an Economic System Which Provides the Greatest Good for the Greatest Number." Unit II. Eleventh Grade Social Studies. Benjamin Franklin High School, Rochester, N. Y. Problem 3, p. 27-30. (Mimeo.)

Problem 3 pertains to the nature and origin of the American money system. The following material is included:

A. Economic Ideas and Terms You Should Know:

The superiority of money over barter.
 Qualifications of good money.
 Bi-metalism, mono-metalism, and Gresham's Law.
 The quantity theory of money and the meaning of inflation.
 The United States Constitution; Article I, Sec. 8.
 Credit.

B. Outline of Content:

History of "hard" money:
 The multiplicity of money types up to 1792.
 The establishment of the decimal system.
 Law of 1792; the 15-1 ratio.
 Law of 1834; gold dollar fixed at 23.2 grains of gold.
 Law of 1837; new ratio 16-1.
 Discovery of gold—1849.
 The fight over bi-metalism versus mono-metalism:
 "The crime of '73."
 Bland-Allison Act—1878.
 Sherman Silver Purchase Act and its repeal—1890-'93.
 The presidential campaign of 1896.
 The Gold Standard Act of 1900.
 The Pittman Act of 1918.
 Effects of the depression of 1929:
 General effects.
 Gold Repeal Resolution—1933.
 Gold Reserve Act of 1934.
 Silver Purchase Act of 1934.
 The stabilization fund.

History of paper money:

Paper money before the Constitution:

Colonial paper issued before the Revolutionary War.
"Continental."

The redemption of colonial currency.

Bank Credit 1791-1861.

First and Second U. S. Banks.

Bank credit of "wild cat" and "pet banks."

Effects of the depression of 1837.

Effects of the "Specie Circular."

Establishment of the National Banks.

Issuance of "Greenbacks."

The reason.

Redemption Act of 1875.

The Federal Reserve System and its credit money.

Types of money in the U. S. today:

An analysis of descriptive nature should be undertaken for each of the following types:

Coin.

Certificates.

Credit (government, bank, and private).

Fiat (if any).

C. Guide Posts:

Money is a means and not an end; it is a "go-between."

Money is essential under any highly organized economic system.

The value of money changes, even when we have a fixed metal coin.

Changes in the value of money bring hardships to one group or another; therefore, a dollar of stable value would be desirable.

The replacement of government bonds by paper money would not necessarily mean inflation, as the money might only be used as a reserve for more bank loans.

Money is a commodity. It responds in value to the laws of supply and demand like other commodities.

(At least until 1933 money was considered and treated as a commodity, but recently there has been a tendency to consider it purely as a medium of exchange.)

EXAMPLE OF A UNIT IN PUBLIC FINANCE

"Governmental Expenditures and Income." Unit 4, Section I.
Social Civics. Grade 12. Senior High School, Springfield, Mo.
p. 10. (Mimeo.)

Point 5 in this section of the Social Civics unit on governmental financing pertains to the payment of taxes. The pupils take up various theories of taxation, as indicated in the following outline:

*Theories of Taxation***1. Equal distribution:**

a. Club dues are equally distributed.

b. Persons who have no children in school may pay as much or more in taxes than those who send children to school.

c. Burden would fall too heavily on people with low incomes.

2. Benefit theory:

a. It is hard to apportion taxes according to the benefit received.

b. Many persons who are poor receive great benefits from the government, but cannot pay taxes.

3. Ability to pay:

a. This leads to progressive taxation—the tax rate increases as the income increases.

b. The proportional tax is also used—the rate is the same for all persons.

c. At times the regressive plan is used to tax business. The license tax decreases as the business increases.

4. Single tax:

a. According to this theory all social progress increases the value of land.

b. People are wealthy because they appropriate the economic rent of land.

- c. Persons are able to hold land for speculation.
- d. The unearned increment belongs to society.
- e. Does all social progress increase the value of land?
- f. If we tax only land value, is the tax flexible enough?
- g. If land values fall, how would the income of the government be affected?
- h. The tax would lead to nationalization of land.

EXAMPLE OF A UNIT ON TYPE OF ECONOMIC ORGANIZATION

"The Origin and Development of Our Democratic Institutions."
Unit III. New York City Public Schools. p. 16. (Mimeo.)

In Section V, "Democracy in Crisis," of Unit III, one of the topics considered is the challenge of other political systems of our day. The following outline is used:

1. The democracies of England and France compared to ours:
 - a. Cabinet vs. presidential systems of government; their respective merits.
 - b. Unitary vs. federal system; their respective merits.
2. Communist dictatorship in Russia; a challenge to democracy founded on the ideals of private ownership and private gain. The challenge lies in ideals, influences, or achievements, such as the following:
 - a. Socialization of wealth.
 - b. Control by the proletariat.
 - c. Planned economy.
 - d. A comprehensive program of social security.
 - e. Political changes: occupational representation, limited suffrage, restrictions on civil liberties.
 - f. Attitude toward religion.
3. Fascist dictatorship in Italy and Germany: a challenge to parliamentary government, to democracy founded on the ideals of individual freedom and laissez-faire, to the alleged cumbersomeness and inefficiency of democratic government. The challenge lies in ideals, influences, or achievements, such as the following:
 - a. Spread of fascism to other countries; fear of fascism in America.
 - b. Planned economy.
 - c. Control by the bourgeoisie.
 - d. Rigid government control of private industry and of capital-labor relations.
 - e. Aggressive nationalism.
 - f. Dictatorship.
 - (1) Practical disappearance of government (local).
 - (2) Practical disappearance of constitutional and parliamentary government.
 - (3) Restrictions on civil liberties.
4. Democracy's answer to the challenge of communism and fascism.

EXAMPLE OF A UNIT ON TYPE OF ECONOMIC ORGANIZATION

"A Comparison of Modern Forms of Government." Contemporary Problems (XI A & B-II). Social Studies. Central High School, Tulsa, Okla. 1938. p. 14. (Mimeo.)

The following are among the topics for study suggested in this course, which compares and contrasts democracy, fascism, nazism, and communism:

1. What were the conditions under which each form of government originated?
2. How do the forms of government compare?
 - a. Executives.
 - b. Legislatures.
 - c. Who is allowed to vote?
 - d. What party system is used?
 - e. Police power.
3. What is the attitude of each toward industry, public utilities, ownership of property?
4. What is the attitude toward classes and race prejudices?
5. What are the living conditions under which people live?
 - a. Houses.
 - b. Food.
 - c. Clothing.
 - d. Luxuries, etc.

6. What is the situation in regard to laboring conditions and unemployment?
 - a. What are the conditions of women workers?
7. What is the position of freedom of press, speech, religion, all individual liberties, education, etc.?

EXHIBIT No. 2736

SUMMARY OF TESTIMONY RELATING TO EDUCATION ¹

By William G. Carr, Secretary, Educational Policies Commission

Education, provided it is right in amount, distribution and kind, can and will improve the economic welfare of the American people. The evidence in support of this conclusion was drawn in part from the recent report of the Educational Policies Commission on *Education and Economic Well-Being in American Democracy* and in part from a nationwide study of citizenship training, recently completed by the Commission.

In applying this generalization the following bill of particulars was developed by the evidence before the Committee.

1. The American people should encourage qualified youth to remain in school, beyond the legal school-leaving age, by:
 - a. Development of technical and vocational schools at the upper high-school and junior-college levels.
 - b. Provision of scholarships, private and public.
 - c. Adapting the course of study to individual needs.
2. We ought at once to remove youth from the labor market by:
 - a. Approval of the Federal Child-Labor Amendment.
 - b. Fixing the school-leaving age at 16 years, at least, in every State.
 - c. Improve the enforcement of school attendance laws, especially for children in industrialized agriculture and street-trades.
3. We should encourage the revision and vitalization of economic education by:
 - a. Better vocational guidance, based on community surveys of occupational information.
 - b. Better vocational training—utilizing public schools, industry, labor and private efforts.
 - c. Better consumer education.
 - d. Conservation education.
 - e. Health education.
 - f. Vocational retraining for workers displaced by illness, accident or technological changes.
4. Education for economic citizenship may be improved by:
 - a. Giving public support to the discussion of important economic issues in secondary schools, colleges, and adult forums.
 - b. Improving the preparation of teachers in economics and the other social sciences.
 - c. Supplying much better teaching materials, and more of them, including textbooks, recordings, pamphlets, photographs and moving pictures.
5. We should use free education as one of the means to improve the nation's economic well-being by:
 - a. Removing the artificial and financial barriers which now bar many youth of real ability from advanced training which would greatly benefit them and society.
 - b. Destroy the monopoly, or partial monopoly, in certain occupations by opening up training opportunities.
6. Let America proceed to make good on the claim that the United States is a land of equal opportunity by:
 - a. State equalization of educational opportunity among school districts.
 - b. Federal equalization of educational opportunity among states.
 - c. Effectively free education.
7. Many factors affect economic well-being; education is only one factor, but a highly important one.
8. Education has many other highly important values which are not primarily economic in nature. Emphasis on the economic values of education in no way ignores or minimizes these other important values.

¹ Presented before a meeting of the Temporary National Economic Committee (TNEC) held in Washington, D. C., April 25-26, 1940.

EXHIBIT No. 2737

STATEMENT SUBMITTED BY CHARLES O'NEILL, PRESIDENT, UNITED EASTERN COAL SALES CORPORATION, NEW YORK CITY

It is difficult to add anything new to a discussion about the bituminous coal industry beyond that which is now known to government. The bituminous coal industry has been under investigation almost continuously since 1917. These investigations have been conducted at different times by hearings before House and Senate Committees, by Commissions established by the President and by the Congress, also in numerous investigations into the regulations and charges for transportation conducted by the Interstate Commerce Commission and more recently by the detailed investigations conducted by the N. R. A., the National Bituminous Coal Commission, now the Bituminous Coal Division under the Department of the Interior.

These latter investigations conducted by the Bituminous Coal Division as to marketing practices, distribution, quality, cost of production and fair minimum prices developed a record of nearly 35,000 pages of transcript and nearly 3,000 exhibits. It is my understanding that the Findings of Fact of these questions which are now in the process of being released by the Examiners for the Division will cover 4,000 pages, containing with the findings, rules and regulations, descriptions of marketing areas, classification of coals, denomination of sizes of coal and prescription of minimum prices.

In inviting me to appear before this committee I was informed that you were seeking the facts with respect to "The combination of changes in the techniques of management, trade, finance, production, processing and distribution, by which the productivity of labor is considerably increased"; and * * * "determining the influences which prevent the expansion of the national income and purchasing power of the people"; and * * * "the role played by technology in economic and business concentrations."

I shall attempt to do no more than bring to the attention of this committee some of the salient facts pertaining to the mining of coal, its place in our national economy and the labor relations within our industry and the competitive situation which confronts coal, a situation over which the producers of coal have comparatively little control. In so far as these facts fall short of satisfying this committee's search for knowledge, I respectfully refer you to the voluminous records obtained in the multitudinous investigations of our industry previously mentioned.

Most of the technological changes in the mining of coal come under the general heading of mechanization. A discussion of the actual progress of recent developments of mechanization in the industry should be ascertained in detail from mining men in different sections of the country. This is because of the wide dispersion of bituminous coal and lignite and the varying natural conditions under which coal is to be extracted in different parts of the country. The application of machinery and power to mining coal varies greatly, depending upon location, and like the industry itself is local in character. There is no such thing as a national coal mine. The output of any particular mine is usually marketed in certain well defined but limited territory. Testimony as to mechanization in its detailed application to any particular field must necessarily come from those who are personally familiar with and responsible for the mining operations in the various localities.

But I have no hesitation in asserting the broad and fundamental proposition that mechanization in the coal industry to date has been a matter of necessity rather than a matter of choice. It has come about not for the purpose of reducing employment, nor for the purpose of increasing the producers' margin of profit. It has been in order to enable the producer to remain in business and to keep his mines open. It is obvious that coal cannot be mined for any great length of time if it fails to return to the producers the cost of production. If competitive conditions, either within the industry or with other fuels and other sources of energy preclude an increased price, a price that will return the cost of production and a profit, then the alternative is either to find some way of reducing the cost of production or else go out of business. Mechanization in that aspect of the matter has been the means of keeping mines open and therefore keeping men employed, both at the mines and in transportation and trade. It is my belief that if there were no mechanization within our industry, unemployment would be greater than it is today rather than less because less coal would be sold and fewer mines would be open.

Resources of bituminous coal are very large and widely distributed. The United States Geological Survey estimates the total reserves of bituminous coal

and lignite in excess of 3,500,000,000,000 tons. An estimate of the amount of bituminous coal actually recoverable in 1923, placed the amount in excess of 1,600,000,000,000 tons. At a normal rate of production of 500,000,000 tons a year, this lower estimate indicates that the available supply will last well over 3,000 years.

Bituminous coal is mined in commercial quantities in 31 states. The states are nearly coterminous with the Union, from Pennsylvania in the east to the State of Washington in the west. Coal is found in great quantities in the Middle West, Southwest, Northwest, South and in the Northeast. Millions of tons of coal are mined in these different sections of the country that are not affected in any way, directly or indirectly, by competition of the coal produced in other faraway sections of the country. Real competition in coal is local.

The bituminous coal industry is composed of many relatively small units. In 1937 there were 6,548 producing mines in the United States, exclusive of wagon and truck mines producing less than 1,000 tons each per year. Only 212 of these mines produced over 500,000 tons each in that year. The largest company produced only about 3 percent of the total output. This is one of the basic facts which account for the too highly competitive situation in the industry.

Since 1923 the industry has had highly competitive conditions. During this period the industry has suffered large financial losses and has lost greatly its proportion of the total energy produced in the country, because of inroads upon its business made by competitive fuels and other sources of energy. The shrinkage in tonnage reflected in loss of business has not tended to "business concentration in coal." Indeed, it has intensified the struggle between competitors to remain in business. In addition to the 6,548 producing mines heretofore mentioned, there are thousands of so-called "wagon" or "truck" mines operating. The last account of the rail, river and truck bituminous coal Code member producers under the Bituminous Coal Act of 1937 was given by the Division as over 13,000.

The principal factors that have affected employment in the bituminous coal industry are:

(a) Improvement in the utilization of coal through improvement in burning equipment; improvement in the preparation of coal at the mines and more careful selection of adaptable coal to plant and equipment by the buyer has resulted in lessening the quantity of coal used each year in the production of an equivalent amount of power and heat. These economies have tended to lessen the total consumption of coal, hence to diminish the mine output and the volume of employment.

(b) The substitution of fuel oil, natural gas and hydro-generated electricity for coal formerly used has likewise tended to labor displacement in the coal industry.

(c) The enhancement of the opportunity for fuel oil, natural gas and hydro-generated electricity to make severe inroads in the markets formerly supplied by coal because of the great increases in rail freight rates for transportation of coal occurring since June 30, 1917. These increases have yielded earnings so high as to be termed "unconscionable" by Interstate Commerce Commissioners and, in my judgment, outrage all sense of decency. Taking June 30, 1917, as 100, the increases in freight rates in existence today for the carriage of coal by rail are shown by the following index numbers: Eastern group, 193; Southern group, 173; Western group, 186; Mountain-Pacific group, 173.

(d) The increasing cost of production at the mines due to increases in wages, increases in general and social welfare taxes, and the increasing cost of supplies add to the industry's competitive difficulties.

(e) The progression of the industry from the ancient hand tools, sledge, wedge, pick, shovel and barrows to the use of explosives, mining cars drawn on tracks by animals, and with the perfection of transmission of compressed air and electricity, to locomotives and mining machines that cut and shear the coal. The only hand tool that has survived to a large extent is the shovel and now it is gradually being replaced by loading machinery.

Great strides have been made in the mechanization of bituminous coal mines since the World War. Some mechanization had occurred before that time. It is not my purpose to attempt to minimize the growth of mechanization of the industry or its effect on labor. The more rapid rate of mechanization which is now apparent in the industry is the result of the effect of the conditions growing out of (a), (b), (c), and (d) heretofore stated. The effect of (a) and (e) has been to keep some of the present portion of bituminous coal production and employment in existence, that had these results not been obtained, would also have shifted with the other millions of tons that have gone to competitive fuels and other sources of power.

I do not believe that mechanization of the mines has generally displaced men from employment. This is not a denial of the fact that workers have been thrown out of employment at bituminous mines as the result of the installation of labor-saving devices. It should be repeated that the installation of mechanical devices in coal mines has made it possible for those mines to continue in operation in competition with rival sources of power and heat and thereby made possible the retention of considerable labor on railroads, boats and trucks employed in transporting the coal to the point of consumption. Improvements in the processes of production of coal and in combustion practice have actually saved many men employment.

The statistics of income published by the Bureau of Internal Revenue show the huge losses sustained by the industry every year since 1925 and tend to prove that (a) and (e) are all that saved what remains of the industry.

The trouble in the industry is that coal loading mechanization comes late and not soon enough to prevent great losses to capital and labor. Increased production per man by the use of labor-saving devices, together with the economies effected in the more efficient burning of coal, have enabled the industry to survive in its present state.

INCREASING ECONOMIES IN COAL CONSUMPTION

While economy in the use of coal is not a form of mechanization in bituminous mines, I wish to briefly point out what has happened in this respect since the World War, and during which time such great progress has been made in decreasing the amount of coal required to do a given amount of work. These economies have been taking place in all lines of coal consumption, but are capable of exact measurement in only a few lines. Tables 1, 2, 3 and 4, attached hereto, show the effect of such economies in detail for the years 1920 through 1938. Recent statistics indicate that further progress was made in 1939.

The tables show that in 1920 the average number of pounds of coal per thousand gross ton miles in freight service on steam railroads was 172; in 1938 the figure was only 115, a reduction of 33.1 percent, or a reduction in use of 25,998,982 tons for the year 1938.

Pounds of coal per passenger train car mile between 1920 and 1938 were reduced from 18.8 to 14.9, a reduction of 20.7 percent, or a reduction in use of 5,546,165 tons for the year 1938.

In electric public utility power plants 3 lbs. of coal were required to generate a kilowatt hour of electricity in 1920; in 1938 only 1.41 lbs. were required, a decrease of 53 percent, or a reduction in use of 57,047,000 tons for the year 1938.

In 1920 in the manufacture of iron and steel, the number of pounds of coking coal required per ton of pig iron was 3,421—in 1938 it was reduced to 2,865, a reduction of 16.3 percent, or a reduction in use of 5,325,551 tons for the year 1938.

These economies have played an important role in retaining the markets for coal and have supplemented the efforts that are being made to further reduce cost by the use of labor-saving devices in the mines.

COMPETITIVE FUELS

The three competitors of coal are fuel oil, natural gas, and hydro-generated electricity, much of the latter being generated in plants built by Government funds.

Fuel Oil.—Exports of coal from the United States, never large, have now practically disappeared, with the exception of shipments into neighboring Canada. (The present European war may temporarily change this condition.) American coals are now facing severe competition in the Canadian market, brought about partly by the action of the Canadian government in absorbing a large portion of the freight rates on Nova Scotia coals to distant industrial centers in Canada, and partly by preferential duties on British coal. In some instances the subventions, or subsidies, range as high as \$2.00 or \$2.50 a ton; the duty is 40 cents a ton less on British than on American coal.

With our normal export situation in this condition, coal produced in this country must find an outlet in the energy markets within the confines of our own borders. These markets, once available almost exclusively to bituminous coal, have now become centers of competition between the four major sources of heat and power, namely, coal, oil, natural gas and hydro-generated electricity.

Competition of coal with the other three sources of energy was but slight in 1918 when coal's share of the total energy market of the country was 70 percent. In the years following, however, production of fuel oil, natural gas and electricity

generated by water power has shown an almost uninterrupted increase, until in 1938 the aggregate production of the three for that single year was equivalent, in B. t. u. content, to nearly 200,000,000 tons of coal.

Fuel oil is used in both the industrial and the domestic field, and its consumption has increased both in periods of prosperity and in periods of depression.

Without considering gasoline and other lighter products of petroleum distillation and their effect upon the declining market for coal, fuel oil—a residual product—is coal's greatest competitor from a quantitative point of view. Its consumption in 1938 was equal to over 102,000,000 tons of bituminous coal on an energy basis.

That most, if not all, of this increased use of fuel oil was made possible through lost markets for bituminous coal is seen by a comparison of the year 1923 with the year 1938. In the latter year, consumption of fuel oil exceeded that in the former year by a coal equivalent of over 35,000,000 tons, while bituminous coal consumption in 1938 was over 178,000,000 tons below that of 1923. (See Table 5.)

That this increased consumption of fuel oil is reflected in unemployment in the coal mining industry, not offset by a counter-balancing increase of employment in the petroleum industry (the petroleum and fuel oil industries employ a relatively small number of men in the production branch compared with coal) is shown by figures covering man years eliminated. The increased use of fuel oil in 1937, over 1923, eliminated a year's work for 48,041 men engaged in bituminous coal mining.

The encroachment of fuel oil upon the bituminous coal market is in no small measure due to the methods in which fuel oil is marketed. Fuel oil is the residual product of petroleum distillation and as such is put on the market at whatever price will enable the producer to dispose of it. This is forcibly illustrated by the fact that according to the figures published annually by the eminent petroleum authority, Joseph E. Pogue, fuel oil sells at the Oklahoma refineries for less than the same refineries pay for the crude petroleum from which the fuel oil is produced. The refiners' losses on fuel oil are recovered from consumers of gasoline, lubricating oil, and other refined products.

Natural Gas.—While the tonnage lost by bituminous coal to natural gas since 1923 has not been as large as the loss to fuel oil, the percentage increase in consumption of natural gas is much greater than the percentage increase in fuel-oil consumption. The coal equivalent of the increase in natural-gas consumption in 1938 over 1923 amounted to 38,075,000 tons, or 137 percent of the 1923 equivalent, and in the previous year 1937, the increase was even more pronounced, amounting to slightly less than 43,000,000 tons, or 154 percent. (See Table 6.)

The effect of the increase in natural gas consumption on coal mine employment is likewise shown by figures covering man years eliminated. The increase in 1937 over 1923, eliminated a year's work for 46,732 men engaged in coal mining. While natural gas is sometimes looked upon as primarily a domestic household fuel, its industrial use accounts for by far the greater proportion of total consumption. This increasing industrial use is in no small degree attributable to the low "dumping" rates at which producers offer gas to industrial users in order to secure an equalized outlet for their pipe-line load. On the average, these "industrial" gas rates are about $\frac{1}{4}$ or $\frac{1}{2}$ of the rates charged domestic or household users, and in some localities the domestic rate is as much as ten times the industrial rate.

Hydro-electricity.—The increased generation of electricity by water power in 1938 over 1923, displaced in that single year 17,562,000 tons of bituminous coal, an increase of 76 percent in coal displacement over the year 1923, and this displacement was made notwithstanding the improvement in efficiency in the generation of electricity by steam. While sufficient data are not available to make complete comparisons of 1938 with 1923, the increased output of electricity generated by water power in 1937 over 1923 had the effect in that single year of eliminating one year's employment for 18,888 men engaged in bituminous coal mining.

This increasing encroachment of hydro-generated electricity on the bituminous coal market is to a great extent made possible by the erection of many large hydro plants, either directly by the government or with the aid of government funds. Their output is sold at prices which bear no relation to the cost of production, since a large portion of the cost of construction is charged to the other factors, such as navigation, irrigation or flood control.

COMBINED EFFECTS OF COMPETITIVE FUELS

A summary of the competitive situation is outlined in Tables 5 and 6. Table 6 shows the combined effect of the encroachment of the three competitive sources of energy on the bituminous coal market.

While most of the calculations have been based upon the theory that the consumption of coal's competitors had been frozen at the 1923 rate, it is by no means to be inferred that these rivals do not have a proper right to their proportionate share of the total energy market. The fact that demands attention is that the output or use of these fuels has increased in a proportion far exceeding the industrial or economic growth of the nation, and the tables show that such increase has been accompanied by a proportionate loss in the market for bituminous coal.

The increased demand for gasoline and the light oils and lubricants refined from crude petroleum has forced an excessive amount of fuel oil on the market at depressed prices. Imports of crude petroleum and gas and fuel oils coming into this country at the rate of between 50,000,000 and 60,000,000 barrels a year on a duty of only $\frac{1}{4}$ cent per gallon (applicable on only part of the imports) have further aggravated the already severe competitive situation. In December, 1939, the Venezuela Reciprocal Trade Agreement reduced the duty to $\frac{1}{4}$ cent per gallon. This implies a greater quantity of foreign oil will be imported.

Sales of natural gas to industrial consumers at unjustifiably low prices have seriously affected the use of bituminous coal. Generation of electricity by water power has in recent years in large degree been financed or subsidized by the federal government.

The importation of foreign oil amounting to about 50,000,000 barrels in 1938, only a part of which was taxed at $\frac{1}{4}$ cent per gallon, caused the displacement of approximately 10,000,000 tons of coal on the Atlantic and Gulf coasts. Under the lower rate more oil will come in.

To the railroads this meant a loss in gross freight receipts of over \$23,000,000 and to the producers of coal, at an average realization of \$1.85 per ton, it resulted in a loss of approximately \$18,500,000 in gross receipts, or a total of over \$40,000,000 in gross receipts to both railroads and coal producers.

For every ton of coal displaced, some employee dependent on the coal industry, either directly or indirectly, loses a day's work. Coal mine labor receives approximately 60 cents out of every dollar received by the coal producers. Railroad laborers receive 45 cents out of every dollar received by the railroads for handling freight.

There are many persons employed indirectly by the coal industry who are adversely affected by the loss of coal tonnage. Tariff protection against the flood of this imported oil, which comes in primarily from Venezuela and the Dutch West Indies, is essential not only to the coal industry but to the American oil industry itself.

The displacement of coal by fuel oil and natural gas, in both of which the employment of labor is very small as compared with coal, and by the generation of electricity by water power, in which the employment of labor is infinitesimal, is an angle of the employment problem to which the public has been seemingly blind.

The fact is that each ton of bituminous coal mined in the United States brings to the mine workers an average of \$1.27 in wages. The labor cost in the production of 4 barrels of fuel oil (fuel equivalent to 1 ton of coal) is about 68 cents. The labor cost in the production of 20,000 cubic feet of natural gas (fuel equivalent to a ton of coal) is about 8 cents. The labor cost in the production of 2,000 KWH of hydro-electric power (energy equivalent to that produced by a ton of coal) is less than one cent.

These figures require no comment. They emphasize their own moral—and the moral is that displacement of coal by substitute fuels is one of the major factors in the country's present unemployment problem.

Three remedies, if applied, would at least partially aid the coal industry and in turn relieve the unemployment situation of the nation. These remedies are: (1) A substantial protective duty on imports of crude petroleum and gas and fuel oils; (2) Regulation by law of the dumping of industrial gas at rates that have no relation to costs, and (3) Withdrawal of the federal government from competition with private industry in the production and sale of electrical energy.

The tabulations which accompany this statement give a detailed picture of the losses sustained by bituminous coal in the past two decades in the share which it has had of the total fuel and energy requirements of the nation.

Table 5 shows the consumption of bituminous coal, fuel oil, natural gas, and the output of hydro-electric power on the basis of coal equivalents, for the years since 1923, as well as the percentage each fuel constitutes of the total. Note how the coal percentage has gone down while the percentages of other fuels have gone up.

The heading on Table 6 is self-explanatory.

Also attached is a statement, Table 7, showing per capita production of bituminous coal, petroleum, natural gas and hydro-generated electricity for certain years since 1910. This is another indication of the effect of these rival fuels and other sources of energy on the coal mining industry.

TRANSPORTATION CHARGES OF BITUMINOUS COAL

Transportation Factors.—Few mines are located at the points of consumption. Of all bituminous coal sold, 85 percent is shipped by rail. Many of these shipments are over considerable distances. On the average, less than half of the price paid by carload consumers of bituminous coal goes to the mine owner and laborer who produce it and more than half goes to the railroads which transport it. Hence the delivered cost of coal is often more affected by changes in freight rates than by changes in cost of mine operation.

Although in recent years competitive forms of transportation, such as motor trucks and waterways, have made appreciable inroads in the movement of coal by railroads, the great preponderance of coal transported is still moved by the rail carriers. The inter-dependence of the railroads and the bituminous industry is shown in the following facts: bituminous coal furnishes the roads with approximately $\frac{1}{4}$ of their total freight tonnage and accounts for 20 cents of every dollar received by them in freight revenue. In turn the railroads are the most important single class of consumers of bituminous coal for industrial purposes, using for locomotive fuel and other purposes approximately one-fifth of all coal produced. Bituminous coal is one of the few commodities or classes of freight where freight rate exceeds the value of the commodity at point of production.

On the revenue coal traffic which the railroads handled during the period from 1928 through 1937, inclusive, the revenue received by the railroads for handling that tonnage exceeded the revenue received by the coal industry for producing and selling the same tonnage slightly in excess of \$1,491,000,000. From a gross revenue standpoint, the transportation of bituminous coal fares far better than the producing branch of the coal industry. It is readily apparent that the relative level of freight rates on bituminous coal is an important factor governing the delivered price of the product to the ultimate consumer.

Since 1922 the general freight rate structure on bituminous coal has been relatively stationary with the exception of intermittent temporary additions to the present rates which have now been made permanent by the Interstate Commerce Commission, but between 1917 and 1922 there were several increases in railroad freight rates on bituminous coal and only one small decrease. As a result of these changes a conservative estimate of the average rate of increase between those two years is 50 percent. As freight charges constituted approximately half of the delivered cost of carload coal shipments, this freight rate increase resulted in an increase of about 25 percent in the delivered cost of coal. This was in addition to the increase in labor cost which, on the basis of delivered prices, amounted to approximately 35 percent. The consumer's price, therefore, had to advance at that time by an average of approximately 60 percent.

Because transportation charges constitute so large a factor in the delivered price of coal, a reduction in freight rates on bituminous coal could do much to enable the industry to check the inroads of competitive sources of energy and to recover for the railroads at least a part of the tonnage already lost by them through the curtailment of coal as a fuel by consumers.

These high rail freight rates, coupled with the construction of improved highways, have encouraged in recent years the movement of bituminous coal by truck. A commodity formerly considered adaptable to rail and water transportation, bituminous coal is now being transported by truck in an amount well in excess of 30,000,000 tons, and official figures available for the year 1936 show a percentage growth in the movement of coal by truck in that year over 1933 of 80.6 percent.

In the year 1936 there were loaded at mines for shipment by water slightly less than 25,000,000 tons of bituminous coal. This was an increase of 91 percent over the 13,000,000 tons so loaded in 1933. In this figure I have not included the substantial tonnage of coal moved from rail mines to river ports for water shipment beyond, nor the large tonnage moved by rail to lower Lake Erie ports for transshipment beyond by water. Neither does it include the coastwise waterborne coal.

In 1936 there were over 52,000,000 tons of coal moved by trucks and waterways, and had this coal been moved by railroad, the gross revenue of the railroads would have been increased over \$92,000,000, of which railroad labor would have received almost one-half. This is estimated by use of average rates.

In order to emphasize these facts as to high rates on bituminous coal, the 27 railroads that in the year 1938 handled 325,537,446 tons of revenue bituminous coal, or 76 percent of the total handled, and which originated 92 percent of all of said coal originated by Class I roads in that year, show for the first 10 months of 1939 the following, quoted from a National Coal Association Bulletin:

"Official figures for the last 2 months of 1939 are not as yet available, but it will be noted that for the first 10 months of 1939 the net railway operating income

of these 27 roads amounted to \$247,368,419, an increase of slightly less than 50 percent over the corresponding 10 months of 1938. After fixed charges had been deducted, these same roads had a net income for the 10 months of 1939 of \$64,393,969, compared with a deficit in 1938 of \$17,679,524, an increase for the 1939 period over that of 1938 undeterminable in percentage, but in dollars amounting to \$82,073,493. Reports for Class I railroads of the United States in the first 10 months of 1939 show a net income of \$23,245,000. Thus the 27 large coal-carrying roads showed a net income of almost 3 times that of the total for all Class I railroads, thus proving that the profits of the large coal-carrying roads are offset against the deficits of the roads that carry little or no coal, and that the net income figure for Class I roads as a whole is in no way representative of the profits derived by the railroads in the handling of bituminous coal traffic."

A tabulated summary of the railroad freight changes affecting bituminous coal since June 30, 1917, as measured by index numbers, is herewith submitted. It is marked Table 8. It shows since June 30, 1917, an increase in the rates in the Eastern group—from 100 to 193—and a little less, but not a great deal less, in the rates in other groups.

INCREASED LABOR COST

The amount wages of coal mine labor have been increased can be obtained by comparing the present scale of base wages with that of 1933. These increases have been of a dual character; first, by an increase in the actual wages paid per day, and secondly, in a reduction of the number of hours in the work-day. On April 1, 1934, the hours of work per day were decreased from 8 to 7 hours, and at the same time the basic inside day wage was increased from \$4.60 to \$5.00. On an hourly basis the increase amounted to 24 percent. Piece work rates were increased by an amount more than sufficient to provide the workers with the same daily earnings for 7 hours work they had received for 8 hours. Between May, 1933 and April, 1937, labor cost per ton increased from 63 cents to \$1.27, an increase of 102 percent, and during the same period the average hourly earnings of bituminous miners increased from 45 cents to 85 cents, an increase of 94 percent. During this same time the cost of living increased only 11 percent, so that real wages of the miners increased practically 75 percent during this period. It is worthy of note that of the 122 industries for which the Bureau of Labor Statistics published average hourly earnings, for December, 1939, only 6 showed higher hourly earnings than did bituminous coal mining. Another factor which has increased the cost of production since 1933 is the indirect labor cost items such as old age and unemployment insurance taxes which are paid by the employer and actually constitute a part of the cost of labor. These costs, which were not in force in 1933, amounted in the year 1938 to approximately 5 cents per ton of coal produced.

The following table shows the changes in wage scales since May, 1933. There has been no change in the wage scale since the April, 1937 wage scale. Therefore, the cost shown, ascertained by the Bituminous Coal Division, of \$1.273 would be approximately correct today.

	Labor Cost Per Ton in Cents	Index No.	Hourly Earnings of Mine Workers in Cents	Index No.
May, 1933.....	63.1	100	45.2	100
October, 1933.....	90.2	143	58.9	130
April, 1934 ¹	109.4	173	71.3	158
October, 1935.....	116.0	184	80.6	178
April, 1937 and subsequent.....	127.3	202	87.8	197

¹ Changed to 7-hour day, 35-hour week.

This statement is not a criticism of these wage levels per se.

LABOR RELATIONS

Everyone is aware of the troubled history of labor relations in the coal mines. In 1933, during the period of the National Recovery Administration, the Appalachian Wage Agreement was concluded simultaneously with the industry's Code of Fair Competition. The Agreement covered all mines in the Appalachian area, including Ohio, and excepting Alabama. It changed the status of 325,000 men and 70 percent of the tonnage production from a non-union to a union basis. It

may be said that this agreement also had a compelling influence on the structure and consummation of agreements in the remaining 30 percent of the industry. Since then, except for 6 weeks' suspension beginning April 1, 1939, there has been peace in the industry.

The Agreement provides for the specification of wages, hours, rules and regulations usually contained in an agreement of this kind. Several features are called to your attention: it provides "That the right to hire and discharge, the management of the mine, and the direction of the working force is vested exclusively in the operator and the United Mine Workers of America shall not abridge these rights." This important clause is strongly enforced by the operators, and it may be added, respected by the United Mine Workers. The Agreement does not provide for, and gives no recognition to, seniority rights. This is considered important, both as to efficiency and safety. It is a union shop agreement, but the union must accept for membership anyone employed by the operators, except one who has already been expelled by the union, which is very rare. It provides for the "check-off" (deduction of dues from payroll), and limits the monthly amount of dues to \$1.50, the maximum initiation fee to \$10 and a maximum national assessment that can be levied in 1 year to \$3.00.

So far as is within my knowledge, and certainly so far as the Central Pennsylvania district is concerned, I believe it may be said that these joint relations have been satisfactory and have been of beneficial influence toward stabilization of the industry. I believe that there is greater cooperation between management and worker in the bituminous coal industry today than at any time in its history, and probably better cooperation than in any other American industry.

Our industry pioneered the 7-hour day, 35-hour week, which went into effect in April, 1934. It is sometimes suggested that it would be desirable from the standpoint of labor in our industry to substitute a 6-hour day, 30-hour week. This has been advocated as a means of spreading employment and making more jobs. The real fact is that such a change would spread unemployment instead of relieving it. The theoretical effect of such a change would be to pay the miners more money for less work and perhaps in periods of peak production at the mines, the temporary employment of some additional men. This would be the theoretical effect, but the practical result would be reduced output per man per day, increased labor cost per ton and collateral increases in almost all the other phases of mining operations. This inevitably would mean increased prices for coal and increased fuel cost to consumers who continued their present rate of coal consumption. The effect in the long run would be an increased incentive to the invention and adoption of still higher efficiencies in the utilization of coal so as to use less, and the more rapid replacement of coal by other sources of energy. It would put an increased premium on mechanization as a means of offsetting the higher labor cost. Taking it all in all, the 6-hour day, 30-hour week, in our industry would inevitably result in less demand for coal, less business for the operator and less employment for labor.

MECHANIZATION OF THE BITUMINOUS COAL INDUSTRY

Table 9 shows that output per man per 7-hour day in all bituminous mines in the United States has increased from 3.88 tons in 1923 to 4.68 tons in 1937, an increase of 20.6 percent. As explained in the table, all figures on output per man per day have been converted to a 7-hour day basis, as the industry, since April, 1934, has been on that basis. In deep mines only, the output increased from 3.84 tons in 1923 to 4.46 tons in 1937, an increase of 16.1 percent. In 1923 the output in strip mines was 6.51 tons; in 1937 it was 14.04 tons, an increase of 115.7 percent.

CUTTING MACHINES AND STRIP MINING

Table 10 shows how the use of cutting machines has increased from 1896 to 1936, the percentage of total production cut by machine increasing from 11.9 to 79.3 and the percentage of underground production from 11.9 to 84.8. Information on stripping is not available before 1914. The percentage of the total production mined by stripping in that year was 0.3—in 1937 it was 7.1. The percentage of total production cut by machine increased between 1914 and 1936 from 51.7 to 79.3 and the percentage of underground production cut by machine increased from 51.8 to 84.8 between the same two years. The table also shows a great drop in percentage mined by all other methods.

MECHANICAL LOADING

Statistics on mechanical loading are not available prior to the year 1923. Table 11 shows that the percentage of underground production mechanically loaded by

all types of equipment increased from 0.3 in 1923 to 20.2 in 1937. There is a breakdown in the table showing amounts and percentages loaded by different types of equipment.

MECHANICAL CLEANING

Mechanical cleaning is a type of mechanization which tends to increase rather than decrease labor requirements. For a good many years there has been an increasing demand for clean coal. Table 12 shows that the percentage of the national production cleaned by wet and pneumatic methods at the mines increased from 2.7 in 1906 to 12.8 in 1937. As will be noted from the table, beginning in 1927, information is available as to the quantity of coal washed at central plants operated by consumers. The grand total of all coal cleaned at the mine and at central washing plants and the percentage of the grand total mechanically cleaned are shown in the last two columns of the table. It will be noted that the latter percentage increased from 5.3 in 1927 to 14.6 in 1937.

MONEY LOSSES

Table 13, "Statistics of Income in the Bituminous Coal Mining Industry", published by the Income Tax Unit, is attached hereto and shows huge losses since 1925, and furnishes in part a compelling necessity for reducing costs of production in this industry.

MINE REALIZATION

The best information ascertainable of the average mine realization for bituminous coal for the years since 1925 is as follows:

Year	Realization	Year	Realization
1925	\$2.04	1932	\$1.31
1926	2.06	1933	1.34
1927	1.99	1934	1.75
1928	1.86	1935	1.77
1929	1.78	1936	1.76
1930	1.70	1937 (includes selling expense)	1.95
1931	1.54		

It will be noted that in 1927 the average mine realization was \$1.99. In no year subsequent thereto, as shown by table 12, has the bituminous industry operated in the black, deficits ranging from \$10,000,000 to almost \$52,000,000 yearly. In 1936 mine realization was \$1.76, or 23 cents below the \$1.99 realization in 1937.

A saving in the price of coal to the domestic consumer naturally leaves such consumer with that saving in money to be used in purchasing other materials, necessaries and luxuries of life, in which the labor factor, while not determinable, is an important factor.

In the case of the industrial consumer, a saving in the cost of coal is reflected in reduced operating costs, and that saving is either passed on to the consumer in a lower priced article, is used in the purchase of other materials in larger quantities or is disbursed to stockholders, and in either event goes into the purchasing power of the nation, thus making for employment in other lines of endeavor.

It is comparatively simple to show by figures that a certain number of coal miners have been displaced or their working opportunities reduced by technologic development, but it is not so simple—in fact impossible—to show by figures, although it is equally true, that such development has retained jobs for miners, due to the fact that such development has enabled coal to hold at least some of its markets, which it would have otherwise lost had some effort not been made to reduce operating and production costs.

It may be true that the "combination of changes" affecting bituminous coal production and distribution has reduced the number of men employed in bituminous coal mining, which is one of the largest labor-employing industries in the country and to which 60 percent of the cost of production is applied in the payment of wages, but there has been some offset in labor employed in other industries or in other occupations, such as in the manufacture of machinery and in the operators of trucks for the carriage of coal formerly transported by railroads.

It is my belief that a greater number of men are employed to haul a given amount of coal by truck than would be employed in carrying the same quantity of coal by rail.

Mechanization in burning coal and in producing coal is the main thing that has enabled the coal industry to retain as much of its market as it now possesses.

I do not wish to be understood as asserting that bituminous coal should have the monopoly of the fuel market. We understand that competitors have a perfect right to take business away from our industry under fair competition. We do feel, however, that it should be on fair prices and not on dumping prices as we believe has been the case from time to time with fuel oil and natural gas. We also believe that government should not subsidize hydro-electric power plants from public funds, taking away business from the bituminous coal industry and throwing miners out of employment, especially when electricity nine times out of ten can be generated as cheaply by coal as it can by water.

We believe the coal industry is essential to the nation's welfare, and even with a further decline in production, will continue to be the most important supplier of the nation's energy.

Failure to stop losses from competitive conditions that sell coal continuously below cost of production will bring impoverishment of workers, bankruptcy of owners, abandonment of mines, equipment and communities, and inevitably produce chaos and labor strife. When it has reached such a state, the cost to consumers and the public is much greater than under stable and rational conditions.

The public must have coal and if it does not "pay as it goes" for the cost of the product, it will pay much more than the accumulated difference between prices and cost of production in rehabilitation charges, relief costs and in exasperating and costly interruptions to industry and transportation, as well as to the depressing occurrences that are part and parcel of great coal strikes or lockouts. In other words, if the industry is not maintained in an efficient and prosperous condition to serve the people at all times, with coal at a reasonable price, the total cost, when settlement is made, will be much greater to all concerned.

It may be that it is one of the insoluble problems of our generation. However, many men in the coal industry are hoping that the present developments as to mechanization; movements designed to lower transportation rates on coal, stabilization of coal prices through marketing agencies and federal regulation, attempts to enlarge coal markets, eliminations of unfair competition by other fuels and sources of energy, or imports of foreign oil, continuing improvement in relations between management and workers, will bring about a solution of the problem and a stabilization of employment in the bituminous coal industry.

1937 ²	1, 853	539	1, 276	18, 390, 000	-26, 952, 000	-7, 662, 000	3, 208, 000	-10, 870, 000

¹ Deficit.

² The figures for 1936 and 1937 are presented in a form directly comparable with previous years by excluding from net income the dividends received on stocks of domestic corporations and interest on government obligations, and by adding to net income the amount of contributions or gifts. In this form the data more nearly reflect the income obtained from coal-mining operations and are comparable with other years.

NOTE.—The years included in the table are the only years for which separate figures for the bituminous-coal industry are available. The data for the years 1917 to 1921, inclusive, are taken from tables prepared by Edward White, Head of the Statistical Division of the Income Tax Unit, for the use of the U. S. Coal Commission. The figures are based on the income-tax reports of all companies making such reports for all five years. The anthracite figures for the year 1925 were furnished by the Assistant Secretary of the Treasury upon request of the National Coal Association; the bituminous figures for the same year were obtained by subtracting the anthracite figures from those of the two branches of the industry combined, as shown in the Statistics of Income of 1925. In 1928 the Bureau of Internal Revenue first published separate figures for the two branches of the coal industry, and the data shown for the years 1928 to 1937, inclusive, are taken from the yearly reports of the Bureau entitled, "Statistics of Income."

National Coal Association, February 20, 1940.

ENGINEERING DEPARTMENT MONOGRAPH NO. 9

TECHNOLOGICAL DISEMPLOYMENT IN THE COAL INDUSTRY

By Walter N. Polakov

LIST OF TABLES

1. Coal Consumption per Capita in the U. S. A.
2. Mechanical Loading Equipment.
3. Tonnage Mechanically Loaded.
4. Productivity per Man-Shift.
5. Speeding Up of Manual Work Alongside of the Mechanized Work.
6. Average Loss of Jobs per Loading Machine.
- 6-A. Average Loss of Employment per 1,000 Tons Loaded by Various Machines.
7. Loss of Employment in Bituminous Coal Mines.
8. Labor Productivity in Strip Mines.
9. Loss of Employment in Anthracite.
10. Disemployment Due to Mechanization, etc.
11. Effect of Slack Operation on Character of Employment.
12. Hourly Productivity of Mine Labor.
13. Reduction of Working Days per Year in U. S. Mines.
14. Working Hours per Week.
15. Productivity per Man per Year.
16. Disemployment Due to Increased Labor Productivity.
17. Coal Consumption per Kilowatt Hour.
18. Coal Consumption.
19. Decrease in Coal-Mine Labor Due to Increased Fuel Efficiency in Cement Plants.
20. Loss of Employment Due to Increased Efficiency in Uses of Coal.
21. Energy Consumption in U. S. A.
22. Hydro-Electric Output and Equivalent Displacement.
23. Loss of Employment Due to Substitute Fuels.
24. Recapitulation—Loss of Employment by Causes.

MOTIVES RESULTING IN DISEMPLOYMENT

All reasons for the wide and fast spread of mechanization in the mines on one side, and technological means for reducing coal consumption on the other, may be reduced to one common motive: increased financial returns on operation. When rationalized, they may appear in a variety of garbs: One company claims that without conveyors they would be forced out of business—that is, financial returns must be increased to make it profitable; another corporation admits that unless they produce the required tonnage within a short season their total annual output will be too small to carry on—that is, speed of production within a busy season enhances financial returns. On the consumer's side, a manufacturer claims that unless he reduces coal consumption per unit of output in his plant he cannot meet competition. Landlord, hotel keeper, railroad manager—all clamor for reduced coal bills. Therefore, technicians of combustion, of insulation, of heat convection, of processing do their bidding by getting more B. t. u.'s from every pound of coal, and less tonnage is necessary.

These financial incentives to mechanization affect the various members of the industry in special ways:

1. *The manufacturer of machines* and mine equipment, attempting to increase his volume of sales, not only advertises his product but, in order to expedite installations, he is frequently willing to finance the buyer. By the time the first payment is made a number of coal miners are laid off as unnecessary.

2. *The coal operator* reduced the cost of production per ton and reduces the payroll, but increases the fixed charges. As a result of \$10,000 invested in a mobile loader some 18 families lose a wage earner. Around 78,000 miners have lost their jobs to machines in this way within the last 15 years.

3. *The coal user* welcomes technological means for reducing coal bills for necessary heat, power, and light—for lowering the amount of coal necessary per unit of his output, be it steel ingots, pulp and paper, sugar, canned goods, etc. Within the last 15 years some 34,000 miners lost jobs on account of such technological "perfection".

4. *The oil refinery and gas well operators*, on the other hand, in order to increase their financial returns, are quick to make alluring offers to reduce the consumer's coal bill by selling him fuel oil or natural gas. These substitute fuels eliminated at least 75,000 jobs in coal mines between 1923 and 1938.

Each of these groups, by attaining their goal of increased financial returns, displace men in the coal mining industry, in rail transportation, in trucking, and in gas works. Each man thus dispossessed of job contributes from \$800 to \$1,200 a year to the business! In return, each of the 81,842 miners who were on relief

rolls in March 1935 received a pittance ranging at the present rate from \$41.88 in West South Central part of the United States to a maximum in Pennsylvania of \$61.77 for *full-time* WPA work.

And when disemployed miners, as all other unemployed, can no longer buy what they need, industry slows down and uses still less coal. So technological unemployment caused a net reduction of another 86,000 jobs in and around mines. This is over and above the jobs lost because of increased productivity of miners and the shrinking consumption of coal.

ECONOMY IN MECHANIZATION

Mr. Percy Tetlow, formerly Chairman of the National Bituminous Coal Commission, said at the 36th Constitutional Convention of the United Mine Workers of America:

"On the technical side, the bituminous coal industry is making every effort to reduce costs by the spread of mechanization. * * * In 1934 it was 12.2 per cent of the total production; in 1938, about 25 per cent. * * * Mechanical loading underground trend will continue upward. * * * The effect upon employment will be pronounced."

From the figures for Illinois alone it is obvious that the reduction in costs, due to mechanization, is very substantial. Compared with hand loading, the production cost per ton of mechanically loaded coal is 43.36 cents, or nearly 20 per cent, below the cost of hand loaded coal. In the case of strip mines the cost is 74.74 cents, or 34 per cent, below the cost of coal hand loaded. The estimate of a mobile loading machine manufacturer places the saving at a more conservative figure of 41 cents per ton.

The Engineering Department of the United Mine Workers of America made a special study of net savings on labor costs per ton in 9 Districts, allowing for explosives furnished by the company and for maintenance and depreciation of machinery. The results indicate a difference varying from a few cents to over 80 cents per ton in the cost per ton of mechanically loaded and hand loaded coal.

Grouping the findings according to Districts the advantages are reduced by the inclusion of unprofitable installations. Differences among Districts vary from 7.25 cents to 39.13 cents per ton. A comparison of the findings of the Engineering Department of the United Mine Workers and the reports of the National Bituminous Coal Commission shows a very close similarity:

Difference in Labor Cost per Ton in 9 District, Mechanically Loaded and Hand Loaded:	
United Mine Workers of America, Engineering Department...	25.47 cents.
National Bituminous Coal Commission ¹	26.10 "

¹ Crude average for nearly corresponding areas.

ECONOMIC SIGNIFICANCE

An inevitable consequence of these financial advantages is the displacement of men by machines. A typical case is reported by a Personnel Director of a large coal operation: "We mine bituminous coal and employ 6,000 men. When we are fully mechanized we will have laid off about 1,000 men." This is a conservative estimate—one out of 6 men displaced. Generally for every 12 men on a mobile loading machine crew about 18 men become unnecessary to produce the same tonnage in a given time.

Now, consider that an average modern mobile loading machine costs \$10,000. It means that for the construction of the machine the labor of some 13,000 man-hours is necessary. And with this investment the labor of 18 miners is eliminated. If miners work 200 7-hour days, a total of 1,400 hours, per year, the eliminated mine labor amounts to 25,200 man-hours for every year of the life of the machine. This means that each year the mining community is deprived of \$16,000 in payroll because of one mobile loading machine. Suppose that the machine is not junked for 5 years. This means that as a result of that \$10,000 investment, the community lost \$81,000 in purchasing power. In other words, business loses *net* \$70,000 of sales in the 5 years of operating that mobile loader and, in addition, pays taxes to support relief agencies.

Obviously, such an economic set-up in an industry producing a non-elastic commodity, such as coal, the use of which cannot be expanded by "creating a desire" to burn more coal than what will do the work, is not sound and, in the long run, ruins not only the industry but the business of the community as a whole.

The recent report of the Bureau of Mines reviewing the catastrophe at Bartley, West Virginia, unequivocally said: "While hand loading methods may not be as efficient as the conveyors used in this mine, there is no doubt that hand loading would be safer . . ." Here, as in the point in question, a million dollars of property damage occurred in addition to the sacrifice of 91 lives for the sake of a few pennies saved per ton of coal—illustrating the perversity of such economics.

The lesson to be learned from this wanton destruction of human lives (which is going on slowly by mechanization and rapidly by explosions) is that *the only sound function of a machine is to reduce the hours of toil and strain involved*; or, in economic terms, it is to improve the standard of living in the community through participation in the accrued benefits.

Instead, the actual numerical shrinkage of employment in bituminous and anthracite mines, according to the U. S. Bureau of Mines, mounted within 15 years (1923–1937) to the staggering total of 272,680 men, and by the end of 1938 reached a still higher peak of 297,250 men.

SHRINKAGE OF DEMAND AND EMPLOYMENT

The demand for coal in the United States grew rapidly until 1920. Since then it has gradually diminished on account of technological advances made in more efficient use of coal, and the use of other fuels instead of coal due to the development in petroleum and natural gas engineering.

If we consider the consumption of coal per capita, we see that between 1870 and 1920—that is, during the end of the machine age and early in the power age—the per capita consumption rose nearly sevenfold (685 per cent), but since then it declined 61.5 per cent by 1937, as is seen from the following table:

TABLE 1.—Coal consumption per capita in the U. S. A.

Year:	Tons per Capita	Year—Continued.	Tons per Capita
1870	0. 90	1920	6. 17
1880	1. 49	1930	4. 36
1890	2. 50	1934	3. 28
1900	3. 54	1937	3. 82
1910	5. 43		

The actual tonnage of coal produced reached a peak in 1923¹ when 564,565,000 tons of bituminous coal were mined by 704,793 men, and the mining of 93,339,010 tons of anthracite gave employment to another 157,743 men. By 1938 bituminous tonnage dropped 38.8 per cent (to 345,400,000 tons) and anthracite shrank by 39.8 per cent (to 46,099,027 tons). The drop in coal production and the increase in labor productivity between 1923 and 1937 made *unnecessary the work* of 214,022 miners in the bituminous field and 58,558 miners in the anthracite field—a total drop of employment in 15 years of 272,680 men. By 1938 the loss of jobs in both fields reached 297,251 men, of which 235,790 men were laid off in bituminous fields and 61,461 men in Pennsylvania anthracite.

It is significant that during these 15 years (between 1923 and 1937) while the output dropped only 20.8 per cent, employment shrank much faster, namely 30.0 per cent. This fact illustrates that, as a whole, the productivity of coal mine labor has rapidly increased, reaching the point where 4 men are doing the work of 5.

In the Pennsylvania anthracite field tonnage production was reduced 39.8 per cent from 1923 to 1938, and employment went down 38.9 per cent. Yet the daily productivity of anthracite miners has increased 36.2 per cent despite shorter hours. This means that 5 men are now doing the work that required 7 men in 1923.

CAUSES OF DISEMPLOYMENT

Such are the gross figures of the ravages of disemployment in the coal industry. Let us now consider in some detail the nature and extent of disemployment caused by technological changes affecting the coal industry. The chief of these are:

- a. Increased productivity of labor;
- b. Improved technique of coal utilization;
- c. Technological development of fuel oil and natural gas;
- d. General business depression.

To apportion precisely the disemployment due to these four causes is not possible because of lack of exact data covering all cases. It is possible, however, to determine with sufficient accuracy the *increase in labor productivity* and therefore the labor displacement by extended mechanization and changes in the manage-

¹ A still higher production was recorded in 1926 due to exceptional conditions and export.

ment technique. The balance of the displaced labor is due to the reduced tonnage resulting from the combined effect of the improved technique in combustion and utilization of power, by the technology of substitute fuels, and by diminished industrial and transport activities and more frugal use of coal for domestic heating during the depression. Of these three causes only the *displacement of employment by substitute fuels* can be calculated with some accuracy. The *economy in coal utilization* may be estimated with less accuracy because of the lack of data from all industries, and the shrinkage of employment due to economic set-back is to be reckoned merely as the remaining balance.

SECTION A. ENGINEERING ESTIMATE OF DISEMPLOYMENT DUE TO INCREASED PRODUCTIVITY OF LABOR

GROWTH OF MECHANIZATION

With the spread of loading machines in the mines since 1923, intensity of work and hourly productivity increased, although perhaps not at a uniform rate since, obviously, the first mechanical loaders were installed experimentally, and new skill and new management technique improved with use. The next period of mechanization had the advantage of experience and loading machines were largely introduced in the most suitable mines. Later installations were made, however, not only in less suitable mines but occasionally in mines definitely not suitable for mechanical loading because of low or weak roof, impurities or bands in the seam, gassy condition, or other factors. Likewise the installment payments, credit extended to operators by machine manufacturers, and high-pressure salesmanship resulted in slightly diminished advantages from loading machines installed in the more recent years. The growth of installation of different loading devices is shown in the following table:

TABLE 2.—Mechanical loading equipment

Year	Mobile Loaders	All Self-Load Conveyors	Scrapers	Increase—Percentage		
				M. L.	Conveyors	Scrapers
1936.....	980	1,170	106	100	100	100
1937 ¹	931	1,053	61	95	90	85
1938 ¹	292	835	18			
1938 ¹	241	749	6			
1939 ¹	295	1,095	28			
Total in 3 years.....	826	2,679	45	88.9	264.4	73.8
Grand total.....	1,808 1,769	3,849 3,732	151 90	179.5	318.9	84.9

¹ Sale.

² Allow in discard in 3 years.

Concurrently with the larger number of loading machines in use, the tonnage loaded mechanically has increased by leaps and bounds since 1923³ as follows:

TABLE 3.—Tonnage mechanically loaded

Year	Bituminous Tons	Percentage of Increase from Preceding Year	Anthracite Tons	Percentage of Increase from Preceding Year
1923.....	1,880,000			
1929.....	37,862,000		3,470,188	
1930.....	46,984,000	+24.1	4,467,780	+28.7
1931.....	47,562,000	+1.2	4,384,780	-1.9
1932.....	35,817,000	-24.7	5,433,340	+23.9
1933.....	37,821,000	+2.1	6,557,267	+20.7
1934.....	41,433,000	+9.6	9,284,486	+41.5
1935.....	47,177,224	+13.9	9,279,057	-0.6
1936.....	66,976,872	+42.0	10,827,946	+16.7
1937.....	83,500,000	+24.7	10,683,837	-1.3

³ We are referring in this analysis to year 1923 as a base year for the following reasons: (1) It was a year of deflection point on the curve between the depression of 1920 and prosperity in the later 20's; (2) It was a year of maximum employment; (3) "The year 1923 witnessed the first widespread attention to a machine which promises even greater results—the underground loader." (Coal in 1923, p. 588, U. S. Geological Survey).

It is also significant that during the past 2 years (1938 and 1939), for which no final record of tonnage is yet available, the number of new machines sold was greatly increased (75.6 percent). Therefore, it may be expected that the percentage of mechanically loaded coal went up and employment correspondingly went down.

Mechanically loaded tonnage in 1937 was 2.2 times greater than in 1929 in bituminous fields, and over 3 times greater in anthracite. Such was the effect of the depression years, in the effort of the operators to reduce pay rolls.

DISEMPLOYMENT DUE TO INCREASED PRODUCTIVITY OF LABOR

The Engineering Department of the United Mine Workers of America has carried on for nearly 3 years exhaustive studies of the effects of mechanization (specifically, of mechanical loading) in the Appalachian Region. These studies were based on mine-to-mine examinations of checkweigh sheets and pay slips in over 90 percent of the mechanized and partly mechanized mines at the time of the study.

From these studies the productivity of loading crews, operating different types of equipment, was determined and compared with the productivity of hand loading in the same mines or adjoining mines in the same seam of coal. Then, comparisons were made of the productivity of the entire personnel in both types of mines, determining all-around productivity per man-day with and without the aid of machines. Similarly, labor costs per ton were computed for both types of mining. Substantially, these field studies disclosed the following *increases* in the intensity of work and hourly (or daily) productivity of men in the loading crews:

TABLE 4.—*Productivity per man-shift (in 204 mines in Appalachian region by types of loading)*

	Hand Loading in Non-Mech- anized Mines	Hand Loading in Partly Mech- anized Mines	Loading on All Types of Conveyors	Mobile Loading
Tons per Man-Shift.....	5.80	7.43	9.04	18.28
Index Number of Men Needed.....	315	246	202	100

Consequently the average output per man in and around mines (*not* loading crew only) has also increased; but what is equally important and significant is the fact that, in the mines which are only partly mechanized, the hand-loading speed also increased as men spurred their production in the race with machines. Thus we notice that the daily output of hand-loaders in partly mechanized mines becomes 28 per cent higher than it is in the neighboring mines in the same seam of coal where *no* mechanized loaders are used.

A similar effect of mechanized portions of work has been observed even in clerical operation, for instance, in bookkeeping by hand in offices where part of the staff did identical work with the aid of machines.

TABLE 5.—*Speeding up of manual work alongside of the mechanized work*

[Insurance Audit]

Year	Manual transactions per man-hour	Mechanized transactions per man-hour	Year	Manual transactions per man-hour	Mechanized transactions per man-hour
1928.....	1.08	None	1933.....	1.31	1.74
1929.....	1.14	"	1934.....	1.40	1.86
1930.....	1.09	"	1935.....	1.40	1.82
1931.....	(¹)	(¹)	1936.....	1.42	1.79
1932.....	1.27	1.71			

¹ Transition of portion of clerks to mechanical work.

In this case the entire force of 608 clerks did manual accounting until 1931, with average transactions per man-hour of 1.09. In 1931 one group of clerks was provided with machines and their daily output increased to 1.78 as an average

of 5 years. This result had a repercussion on the remainder of the clerks who were still without machines, and their average output per man-hour for an average of 5 years went up to 1.36, or 24.77 percent higher than it was before any machines were used by the company. Professor T. North Whitehead (Harvard University, Cambridge, Massachusetts) reported similar results from experiments conducted among a group of factory operatives, in "Social Relationships in the Factory"—The Human Factor, Vol. IX, No. 11, November 1935.

From the studies of the Engineering Department of the United Mine Workers of America, some definite relationships between disemployment per loading device of each type were established as follows:

TABLE 6.—Average loss of jobs per loading machine

	<i>Men</i>
Mobile loaders.....	18.9
Scrapers.....	7.47
Self-loading conveyors.....	0.50
Pit car loaders and hand-loaded conveyors.....	0.48

Similarly, for any given relation in the use of these devices the loss of employment per 1,000 tons was computed:

TABLE 6-A.—Average loss of employment per 1,000 tons loaded by various machines

	<i>Men</i>
Mobile loaders.....	0.812
Scrapers.....	0.529
Self-loading conveyors.....	0.566
Pit car loaders and hand-loaded conveyors.....	0.465
Weighted average.....	0.693

On the basis of these test data it appears that in 1936 we had labor displacement by types of loaders as follows:

TABLE 7.—Loss of employment in bituminous coal mines

Mobile loaders:	
Tonnage loaded, 40,969,625 tons.	
Number of men needed to load it by hand, 44,532 men.	
Actual employment, 11,252 men.	
Men displaced, 33,270.	
Conveyors (duckbills):	
Tonnage loaded, 3,240,411 tons.	
Number of men needed to load it by hand, 3,522 men.	
Actual employment, 1,688 men.	
Men displaced, 1,834.	
Scrapers:	
Tonnage loaded, 1,272,466 tons.	
Number of men needed to load it by hand, 1,383 men.	
Actual employment, 710 men.	
Men displaced, 673.	
Pit car loaders and hand-loaded conveyors:	
Tonnage loaded, 21,494,370 tons.	
Number of men needed to load it by hand, 23,363 men.	
Actual employment, 14,060 men.	
Men displaced, 9,303.	
Total displacement by loading machines in 1936:	
	<i>Men</i>
Mobile loaders.....	33,270
Self-loading conveyors.....	1,834
Scrapers.....	673
Pit car loaders and conveyors.....	9,303
Total.....	45,080

Displacement of men on the basis of 1937 tonnage mechanically loaded would be about 56,163 men. This estimate does not include the strip mining responsible for large additional disemployment.

STRIPPING

Stripping operations are characterized by very high labor productivity, as shown in the table below:

TABLE 8.—*Labor productivity in strip mines*

Year	Bituminous		Anthracite	
	Per Man-Day	Per Man-Year	Per Man-Day	Per Man-Year
1936.....	12.60	<i>Tons</i> 2,330	6.68	<i>Tons</i> 1,330
1937.....	14.08	2,548	6.75	1,242

On this basis, to produce the difference between 11,940,134 tons stripped in 1923 and 32,074,557 tons stripped in 1937 (bituminous coal), would have required 22,100 men working at the average underground rate of production, but actually only 2,548 men were required to produce this additional tonnage of stripping. Therefore, the loss of employment in bituminous coal was 19,552 men by 1937.

DISEMPLOYMENT IN ANTHRACITE

Considering the loss of employment in the anthracite operations, we must note that the great increase in labor productivity (40.1 percent per man-hour, from 1923 to 1937) has been nearly balanced by the reduction of working time. The number of working days per year was reduced 35.8 percent and the working hours were cut to 7 per day. In this way the technological displacement in the anthracite deep mines was compensated by reduced working time.

In other words, to produce the tonnage of 1937 (51,856,433 tons) would have required the labor of 99,057 men with the productivity prevailing in 1923, but, with shorter time and greater labor productivity, the actual requirement was for 99,085 miners. A small gain of 28 men—less than three hundredths of one percent.

At the same time the expanded stripping operations in the anthracite field caused some disemployment.

ANTHRACITE STRIPPING

Tonnage stripping in open pits in Pennsylvania increased between 1923 and 1937 by 3,675,395 tons (from 2,020,623 in 1923 to 5,696,018 in 1937). With the labor productivity actually existing in deep mining, the recovery of this tonnage would have required the employment of 7,040 miners. Actually, however, the stripping of 5,696,018 tons in 1937 was done by 4,585 men. Thus the "labor saving" in anthracite strip mining was equal to 2,455 men.

TOTAL DISEMPLOYMENT IN ANTHRACITE

We can now combine the gain in deep mining and the loss due to stripping as reflected in computed disemployment of anthracite miners, as follows:

TABLE 9.—*Loss of employment in anthracite*

Deep mines—gain.....	<i>Men</i> 28
Strip mines—loss.....	2,455
Total loss.....	2,427

TOTAL DISEMPLOYMENT DUE TO MECHANIZATION

Combining the disemployment figures for the bituminous coal fields, based wholly on our field observations and study of mechanization with those computed for the Pennsylvania anthracite, we get a total of disemployment resulting from increased productivity of labor due to mechanization and such managerial methods as go with it, as follows:

CONCENTRATION OF ECONOMIC POWER

17543

TABLE 10.—Disemployment due to mechanization, etc.

	<i>Men</i>
Bituminous deep mines.....	56,163
Bituminous strip mines.....	19,552
Total.....	75,715
Anthracite deep mines—gain.....	28
Anthracite strip mines—gain.....	2,455
Anthracite total.....	2,427
Grand total.....	78,142

¹ It is important to note that this engineering computation compares with statistical calculations based on Bureau of Mines data of labor productivity within one quarter of one percent (75,905 and 75,715).

INFLUENCE OF MACHINES ON SEASONAL UNEMPLOYMENT

Several studies illustrate the effect of the mechanical loaders on employment in slack seasons. Inasmuch as the installments and interest on the investment have to be paid even while idle men are off the payroll, the management seeks to use machinery more uniformly and lay off hand-loading men. Thus in our studies we have a record comparing man-days worked by mechanical crews and hand and pick miners during high and low production months:

TABLE 11.—Effect of slack operation on character of employment

	Full Month	Slack Month
Hand loading and pick mining.....	1,200	300
Mechanical operation.....	2,830	2,570

The above shows that while in dull seasons only 25 percent of hand miners are employed, nearly 91 percent of mechanized operations are still going on.

ACTUAL VS. STATISTICAL MEN

Because of uneven distribution of employment throughout a year, and more particularly because of the widespread practice of sharing the work among miners, the computed number of men are not necessarily wholly out of work. In other words, some of the 78,140 men are undoubtedly sharing some work with those regularly employed. As a result they work per week generally less than 5 days.

SECTION A-1. STATISTICAL BASIS FOR ESTIMATE OF DISEMPLOYMENT

SHORTCOMINGS OF STATISTICAL DATA

Obviously, statistical compilations can never be as reliable and as detailed as engineering estimates based on test data. Statistical errors may, however, sometimes cancel each other.

To use the statistics of the Bureau of Mines for determination of displacement of miners by increased mechanization requires several adjustments. The Bureau itself admits that "until the American coal industry arranges to keep an accurate record of the man-days or man-hours of employment, all computations . . . will remain subject to qualification." (Minerals Yearbook, 1939, p. 790.)

Moreover, the Bureau of Mines statistical method does not recognize the principle of dimensionality and adds together manual production and mechanical production in its attempt to determine the "average" rate of productivity. Therefore, the Bureau of Mines had no knowledge of relative productivity of different types of mining equipment. Furthermore, part-time employment is not taken into account when an attempt is made to compute the total man-hours of work and base on it the labor productivity.

Therefore, in order to compute the displacement of labor by mechanization we must not only accept admittedly incomplete records of the Bureau of Mines, but

also lump together: (1) psychological effect on the efficiency of manual operations; (2) productivity of all types of mechanical loading confounded with productivity of hand mining; and (3) consider *all* operations in and around mines as a whole. And after that we must correct year-by-year records for (a) variations in tonnage; (b) variations in number of days worked per year; (c) variations in number of hours per day, and leave as an indeterminate factor all changes in management technique, in the use of explosives, personnel relations, etc., etc.

TOTAL INCREASE OF LABOR PRODUCTIVITY

Statistics of the Bureau of Mines determine the productivity of labor by dividing the total tonnage output reported for the year by the average number of miners employed. This tonnage per man is then divided by the reported number of days (average) worked at the tippie, and this result is accepted as the rate of productivity per man-day in the mine.

Even with so crude an approximation of labor productivity, its rise is definitely noticeable. In 1923 the Bureau of Mines (Geological Survey) made note of the appearance of the underground loading machine. Since then the portion of tonnage mechanically mined and loaded has steadily reflected its influence on Bureau of Mines records.

The productivity of mechanized mines influences the average productivity of all mines in the country, and the intensification of work is clearly seen from the rapid increase of productivity per man-hour. Since 1923 it has grown as follows:

TABLE 12.—Hourly productivity of mine labor

Year	Output in Tons		Percentage of Increase	
	Bituminous Per Hour	Anthracite Per Day ¹	Bituminous	Anthracite
1923	0.555	2.21	0.0	0.0
1929	0.602	2.17	+8.4	-1.8
1930	0.632	2.21	+4.9	+1.8
1931	0.659	2.37	+4.3	+7.2
1932	0.645	2.54	-2.1	+7.2
1933	0.596	2.60	-7.6	+6.1
1934	0.590	2.53	+0.5	+2.6
1935	0.642	2.68	+7.7	+5.9
1936	0.658	2.79	+2.5	+4.1
1937	0.672	2.77	+2.1	-0.7
1938 ²	0.655	2.79	-2.5	+0.7
Total Increase			+18.01	+26.24

¹ No reliable record of hours worked in anthracite mines is available.

² The data for 1938 are questionable.

This increase of hourly productivity of a miner from 0.555 tons in 1923 to 0.666 tons per man-hour for an average of the last 3 three years indicates the intensification of labor by 20 percent—that is, 4 men do the work previously done by 5 men.

DECREASE OF WORKING DAYS PER YEAR

With such increase in productivity per man-hour the total output would increase in proportion if the work time remained unchanged. Since, however, the demand for coal was declining while labor productivity was rising, the industry had two possible courses of action: either to dismiss a large number of men or to reduce working time. Actually, both courses were taken. By 1938, the bituminous mines reduced the number of *working days per year* to 73 percent, and anthracite mines to 76 percent, of the days worked in 1929.

TABLE 13.—Reduction of working days per year in U. S. mines

Year	Bituminous	Anthracite	Year	Bituminous	Anthracite
1923	179	268	1934	178	207
1929	219	226	1935	179	187
1930	187	208	1936	199	192
1931	160	181	1937	196	185
1932	145	162	1938	160	171
1933	167	182			

¹ Bureau of Mines—Pennsylvania Anthracite.

But the drop in tonnage was even greater than the reduction in the number of days worked. Thus 1938 bituminous tonnage was 64.5 percent of the 1929 output, and 1938 anthracite tonnage was 70 percent of the 1929 output. This situation, together with the steadily increasing productivity of labor, led to wholesale dismissals of miners.

REDUCTION OF HOURS PER DAY

To counteract this gradual starvation of miners through loss of jobs, the United Mine Workers of America secured a shorter working day to provide work for more men. This reduction of working hours per week in the bituminous coal industry was as follows:

TABLE 14.—Working hours per week—Bituminous coal

Year	Hours per Week	Percentage	Year	Hours per Week	Percentage
1913.....	51.6		1936.....	35.1	72.5
1929.....	43.4	100.0	1937.....	35.1	72.5
1934.....	40.0	82.6	1938.....	35.02	72.3

Stated differently, the average number of hours a miner worked in 1929 was 1,774, and in 1938 the average was 1,120 hours—a reduction of 36.9 percent in annual time.

PRODUCTIVITY PER MAN-YEAR

Balancing in this manner the intensification of labor (per hour) against reduced working time (per year), we find that the reduction in working time was inadequate to balance the increased labor productivity, and the net annual productivity per man rose between 1923 and 1937 by 13.1 percent in bituminous operations. In the anthracite field, however, the balance was apparently reached.

TABLE 15.—Productivity per man per year

Year	Bituminous		Anthracite (Tons per Man-Year)	Year	Bituminous		Anthracite (Tons per Man-Year)
	Tons per Man-Year	Hours per day			Tons per Man-Year	Hours per day	
1923.....	801	8.06	592	1936.....	920	7.02	535
1932.....	762	8.10	411	1937.....	906	7.01	522
1934.....	785	7.27	473	1938.....	736		478

¹ Estimate.

This indicates a net annual increase in bituminous coal output per miner under the existing conditions of 13.1 percent.

COMPUTED DISEMPLOYMENT—BITUMINOUS

Consequently, leaving for the time being out of consideration the effect of technology on coal demand, we see that the disemployment of miners due exclusively to *changed method of production* is 13.1 percent. In total numbers this represents a loss of jobs for 67,300 men between 1923 and 1937.

ADJUSTMENT FOR TIME AND LABOR INTENSITY

A more dependable method of determining the displacement of miners by means of their increased productivity would be to adjust the Bureau of Mines records to uniform 7-hour day and to the uniform number of days, and then to compute the labor requirements and actual employment in order to determine the number of jobs permanently eliminated by the recorded intensification of labor.

Thus, if in 1923 men worked 7 hours per day and 179 days with the same productivity as they worked in 1938, then the man-year production would have been 820.7 tons. Again, if in 1938 labor productivity was as low as it was in 1923, the productivity per man-year would have been only 621.6 tons.

Therefore, under old efficiencies, to produce 345,400,000 tons would have required per year 555,305 men as against the actual employment of 469,000 men, representing the disemployment in 1938 of 86,305 men.

By the same method of calculation we find that disemployment due to increased labor productivity has changed as follows:

1936.....	89,028 men
1937 ¹	75,905 "
1938.....	86,305 "

¹ Year comparable with the field study of the Engineering Department, United Mine Workers of America, to determine labor productivity by types of machines and mining.

TOTAL DISPLACEMENT OF LABOR DUE TO INCREASED LABOR PRODUCTIVITY

Recapitulating now the results of our field tests and the Bureau of Mines statistics, we can state with reasonable accuracy the extent of destroyed opportunities for employment due to increased productivity of labor modified by reduced working time.

TABLE 16.—Disemployment due to increased labor productivity with mechanical and managerial developments—1923-1937

Class of Labor	Number of Jobs Eliminated	Computed on Basis of Bur. of Mines data
Bituminous:		
Deep mines.....	56,163	
Stripping.....	19,652	
Total.....	75,715	75,905
Anthracite:		
Deep mines.....	428	
Stripping.....	2,455	
Total.....	2,427	2,427
Grand Total.....	78,142	78,332

Inasmuch as total shrinkage of employment, 1923-1937, was 272,680 men (214,022 in bituminous and 58,658 in anthracite), of which the disemployment due to mechanization, managerial technique, and general increase of labor productivity was 78,142 men, the loss of employment by the balance of 194,538 miners is to be accounted for as the result of (1) increased efficiency of combustion, (2) technological progress in the use of substitute fuels, and (3) general business depression.

SECTION B. TECHNIQUE OF COAL UTILIZATION

FUEL INDICES

The technological progress has affected the demand for coal as the efficiency of combustion has been gradually increasing through more scientific combustion control, automatic stokers, pulverized coal burners, and the use of pre-heaters and economizers in boiler-room practice, and the perfected design of steam turbines, locomotives, kilns and other power- and heat-utilizing equipment.

The most accurate index of this progress is to be found in the records of the Electric Utilities Control Stations (Federal Power Commission and Edison Institute). Thus the generation of one kilowatt hour of electric energy requires less and less coal, as can be learned from the following table:

TABLE 17.—Coal consumption per kilowatt hour

ELECTRIC CENTRAL STATIONS

Year	Pounds per kw. hr.	Year	Pounds per kw. hr.
1902.....	6.40	1934.....	1.45
1917.....	5.47	1936.....	1.44
1923.....	2.40	1937.....	1.43
1929.....	1.69	1938.....	1.41
1933.....	1.47		

This record indicates a reduction of coal consumption since 1923 to 1937 of 40.4 percent per kilowatt hour.

A similar reduction of coal consumption per unit of output was recorded in transportation (R. R., Class I). There coal consumption per thousand ton-miles of freight dropped as follows:

TABLE 18.—Coal consumption

Year	Per M. Ton-Miles Freight Pounds	Per Passenger Car-Mile	Year	Per M. Ton-Miles Freight Pounds	Per Passenger Car-Mile
1920	174	18.8	1934	122	15.2
1923	150	18.1	1936	119	
1929	125	14.9	1937	117	
1933	121	15.2	1938	116	

This record indicates a reduction of coal consumption in 15 years (1923-1937) by 22.0 percent in freight service and at least 14.3 percent in passenger service.

In the study of engineering progress in the cement industry (which is especially significant because one-third of the total labor needed to produce cement is the labor of coal miners), we notice the extended use of Lepol Kilns and numerous other innovations which cut the consumption of coal by about 2 tons per thousand barrels produced. In terms of labor elimination this fuel efficiency appears as follows:

TABLE 19.—Decrease in coal-mine labor due to increased fuel efficiency in cement plants, 1927-35

	1927	1935	Percentage of Decrease
Average number of man-hours consumed in coal per 1,000 barrels of cement—coal mines and railroads	257.7	199.8	22.7%
Mine labor per 1,000 barrels of cement	249.0	200.0	20.0%

In other industries, notably steel and iron, paper and pulp, food products, etc., a considerable fuel economy has likewise been attained in the last decade or two. Thus, in blast furnace practice fuel consumption dropped from 3,325 pounds per ton of pig in 1923 to 2,838 pounds in 1935, or 14.6 percent reduction.

Likewise, domestic heating has been made more efficient, partly through the use of stokers, automatic controls, and improved heating equipment, and partly to better insulation of houses.

To compute the actual number of miners displaced by this advanced technology is not simple because some industries (public utilities) continue to grow, and what is lost due to efficiency is gained due to increased business. Other industries (railroad) are shrinking, and increased efficiency is applicable to a smaller proportion of fuel demand. In other words, while theoretically the potential loss of employment in producing coal for the electric public utilities would have been over 30,000 people, the increased business of public utilities reemployed almost all those displaced by higher efficiency, and the resulting net loss of employment is but 8,000 men.

On the other hand, the total decrease in coal consumption depends not only upon the efficiency of coal utilization but also upon the tonnage used in each industry.

The average consumption of bituminous coal between 1919 and 1935 was distributed as follows:

Electric power stations	8.4%
Railroads, Class I	23.4%
Iron blast furnaces	10.1%
Cement plants	1.6%
	43.5%

It is somewhat hazardous to compute the total effect upon less than a 50% sample, but revising the figures in the light of 1937 technical reports and coal consumption, and then translating the tonnage of coal saved into man-years of eliminated work, we get a reasonable approximation.

LOSS OF EMPLOYMENT DUE TO HIGHER EFFICIENCY OF COAL UTILIZATION

Such an adjusted estimate of jobs lost due to increased efficiency in the utilization of heat, light, and power appears to be:

TABLE 20.—Loss of employment due to increased efficiency in uses of coal

Electric utilities.....	7, 870 men
Steam railroads.....	5, 895 "
Manufacturing and domestic uses.....	20, 195
Total.....	33, 960 men

SECTION C. TECHNOLOGICAL DISEMPLOYMENT DUE TO SUBSTITUTE FUELS

GENERAL DEVELOPMENTS

The last score of years witnessed a rapid advance in technique of recovery of petroleum and natural gas. Coupled with the progress in the field, there was notable expansion and change in the technique of refining and the transportation of gas and oil by pipe lines. Widespread motor vehicle transportation caused an increased demand for gasoline; hence the by-product of the refineries—fuel oil and Diesel oil—appeared on the market in great quantities. The price was juggled so that the main portion of production cost was borne by the consumers of gasoline, who in this way subsidized fuel oil and made it a competitor of coal. Furthermore, the development of the Diesel engine and its widespread adaptation to transportation, municipal and public works had its effect. While in 1929 only 430,000 horse power of Diesel engines were sold, the sale of Diesels in 1939 exceeded 2,144,000 horse power, making total installations by 1940 of 15,265,000 horse power using heavy oil, partly instead of gasoline but largely replacing coal.

Similarly, natural gas, through long transport pipes, reached remote parts of the country and, with the aid of technical improvements in pumping stations, automatic heaters, metallurgical processes, etc., became a competitor of coal and manufactured gas.

DISPLACEMENT OF COAL BY OTHER ENERGY SOURCES

National consumption of coal has steadily declined after it passed the peak in 1920, but the total consumption of all fuels and water power is still increasing:

TABLE 21.—Energy consumption in U. S. A.

[In trillions of B. t. u.]

Year	Trillions B. t. u.	B. t. u. per capita	Year	Trillions B. t. u.	B. t. u. per capita
1896-1900.....	6, 690	88. 0	1934.....	20, 431	161. 8
1921-1925.....	21, 308	192. 0	1935.....	21, 615	169. 5
1932.....	18, 022	144. 2	1936.....	24, 367	189. 7
1933.....	19, 317	153. 5	1937.....	25, 739	199. 0

As we have nearly reached the index of physical production of 1929 we have increased the per capita energy consumption, and the total quantity of fuels used is 21 per cent higher in 1937 than it was in 1923, while the total coal consumption within the same period dropped 24 per cent.

INCREASE IN FUEL OIL USE

In 1923 we consumed 261,388,000 barrels of fuel oil; in 1937 our consumption was:

Gas oil and distillate fuels.....	116,841,000 barrels
Fuel oil (residual).....	315,514,000 "

Thus the increase in the use of fuel oil alone was 64,126,000 barrels, which is equivalent (1 ton of bituminous coal=4.37 barrels) to 14,674,140 tons of coal. To mine this quantity at the rate prevailing in 1937 would have required the work of 16,000 miners.

INCREASE IN NATURAL GAS USE

The growth of natural gas uses in industry and in homes was likewise rapid, and even more disastrous to the coal industry. Since 1923 the uses of natural gas have increased as follows:

<i>Class of Service</i>	<i>Increase</i>
Domestic consumption.....	211,016,000,000 cu. ft.
Industrial.....	319,635,000,000 "
	530,651,000,000

This quantity is equivalent (1 ton of coal=24,372 cu. ft. of gas) to 21,772,977 tons of bituminous coal. This tonnage, if needed, would have provided employment to 23,900 men in the coal mines.

INCREASE IN HYDRO-ELECTRIC POWER

In addition to the use of these substitute fuels made possible by the advance in fuel technology and power engineering, the capacity of power dams, hydro-turbines, and hydro-electric plants increased rapidly. The hypothetical displacement of miners by the hydro-electric power is shown in the following table:

TABLE 22.—Hydro-electric output and equivalent displacement

Year	Hydro-Electric Output 1,000 kw. hrs.	Equivalent Tons of Coal ¹	Equivalent Requirement of Miners ²
1920.....	15,278,872	22,018	} 23,390
1925.....	21,494,119	22,568	
1930.....	30,941,508	25,063	} 26,440
1935.....	38,381,384	28,018	} 34,800
1937.....	43,702,000	31,465	} 34,640

¹ Efficiency of each given year.
² Productivity per man-year for given year.

POTENTIAL EMPLOYMENT IN LIEU OF SUBSTITUTE FUELS

In this manner we can visualize fairly well the employment necessary to produce coal which was replaced by substitute fuels.

TABLE 23.—Loss of employment due to substitute fuels

Fuel oil equivalent to.....	16,100 men
Natural gas ".....	23,900. "
Hydro-electric power ".....	34,540 "
Total.....	74,540 men

SUMMARY OF TECHNOLOGICAL DISEMPLOYMENT

While the items reviewed above are not strictly additive, they indicate the relative role each type of technological displacement of labor plays.

TABLE 24.—Recapitulation

EXHIBIT No. 2739

TECHNOLOGICAL CHANGES IN BITUMINOUS COAL MINING AND THEIR SOCIAL-ECONOMIC CONSEQUENCES

By Walter M. Polakov, Director, Engineering Dept., United Mine Workers of America

The coal industry has been technologically backward from its beginning in 1720 until the end of the last century.

The first issue on machine mining arose in 1901 when, at the 12th Annual Convention of the United Mine Workers of America, it was pointed out that 12,000,000 tons more of bituminous coal were produced by the cutting machine in 1899 than in 1898. During that Convention the contention of the miners was stated for the first time that "If machine mining is to be the system through which coal is to be produced in the future and if the cost of production is thereby lessened, labor is entitled to and should receive a reasonable portion of the financial advantages".

To understand the revolutionary changes brought about by the mechanization of mining it may be advantageous to visualize the labor process in coal mining. Coal deposits are generally deep underground. To reach the seam of coal it is necessary to sink a shaft to the level of the coal deposit or make an entry into the outcropping seam as a drift or slope from the surface. Then a tunnel is dug (called an entry) from which tunnels (called rooms) branch off, from which coal is removed to the main tunnel and then to the surface.

In the manual operation the miner using a pick undercuts the layer of coal (an operation called "kerfing"); then drills holes with a breast auger, places explosives into these holes, and blasts the "face". The fallen, broken coal is then loaded with shovels into cars. These cars are pushed by men to the main haulage way from which they are taken out by mules or horses to the surface, or to the base of the shaft and then hoisted to the surface.

Obviously, working underground, the first requirement is fresh air to breathe. In former days it was furnished from the main entry by creating a draft by means of an air shaft at the end of the mine, on top of which fire was built to create a sort of chimney draft effect. With deeper mines and longer tunnels it became necessary to force the air to men underground by means of fans. Both fans and hoists were driven by a steam engine on the surface as the presence of explosive gas and coal dust inside the mine precluded the use of boilers and steam locomotives inside the mine.

When the first attempts at mechanization underground were made, electricity was not yet available. So the early machines, few in number, were driven by compressed air. But when electricity ceased to be only a source of illumination and means were discovered to generate electric power, the mechanization of mines became feasible to a greater extent.

The first step in mechanization was made when coal cutting machines were introduced to displace hand kerfing. By 1930, 81 percent of coal mined underground was already cut by machines, and in 1936 the percentage was 84.8.

It is noteworthy that in non-union areas a much larger percentage of coal was mined by pick than in unionized areas (Central Competitive Field) where most of the coal was mined by machine.

Thus the 1923 record shows:

	<i>Pick Mined Percentage to Total</i>
Non-Union Area:	
Northwest Maryland.....	83.5
Northwest Colorado.....	48.2
Tennessee.....	31.6
West Virginia.....	20.0
Fayette and Westmoreland Co., Pa.....	50.0
Union Area:	
Ohio.....	2.7
Illinois.....	5.5
Indiana.....	7.3
Pennsylvania.....	33.1

This placed upon union miners the first brunt of the displacement of men by machines.

As a result of this first stage of mechanization, employment in the West declined by 25 per cent between 1923 and 1929, while total tonnage was only 4 per cent

lower, and in the Southern Appalachian Region 44,500 tons more coal were produced in 1929 than in 1923 with 25,500 fewer workers.

Mass disemployment was aggravated by the receding coal market in 1923 when 1,745 mines were shut down and some 85,000 men were squeezed out of employment.

As the use of coal cutting machines became general, the electrification of mines revolutionized also the haulage method. Mules were practically displaced by 1924, when 3,585 mines producing 88 per cent of the total tonnage used locomotives. This change displaced mule drivers, stable men and others by a few motor-men.

Mechanical loading devices, while known and experimented with for some time, did not play any important part until about 1923. In that year President John L. Lewis of the United Mine Workers of America called a conference of union leaders to discuss loaders and conveyors and to work out a set of principles with reference to them. This awoke the statisticians of the Bureau of Mines, who made the first reference to this type of mechanical loading in the report on coal for 1923.

The decision reached at the conference called by Mr. Lewis ruled: "That it be the understanding in this matter that in districts where coal loading machines are in operation, the Mine Workers will insist upon the appointment of a joint commission in their respective districts to determine exactly what the machine will do, and that all data on the subject secured in the respective districts through the negotiations of commissions, be submitted to the International Union and that in all districts where it is necessary to make arrangements governing the operations of these machines . . . and that the respective districts shall adopt such *day wage scale* for temporary purposes as they may deem necessary to protect their membership."¹

In the interim the widespread introduction of loading machines displacing the most numerous group of mine labor, the loaders, became so threatening to employment that in the 1937 Appalachian Wage Agreement a special clause was included calling for a Joint Committee on Mechanized Mining, whose duty it shall be to study "the problems arising from mechanization of bituminous coal production by the use of conveyors and mobile loading machines for the area covered by the Appalachian Joint Wage Agreement, including the problem of displacement of employees."

Despite this contractual agreement, the operators consistently refused for over two years to cooperate in such a joint study and even refused, with only two exceptions, to have union representatives obtain data from their mines.

At that time the only official study in existence was that of the Bureau of Labor Statistics, "Employment in Relation to Mechanization in the Bituminous Coal Industry" (Monthly Labor Review, Vol. 36, December 1933, p. 264). At that time some mines in Illinois, Pennsylvania, and Wyoming already had mechanical loaders and conveyors in use.

These mines produced about 5,650,000 tons of coal in 1931 and employed some 4,000 miners. Some of these mines were selected for the study which disclosed that mechanical loading increased the average output per man per day by 46.8 per cent for all mines in the sample (partly and fully mechanized).

The fully mechanized mines *alone* showed the increase in productivity of 65.7 per cent.

Such a reduction of labor force by displacement of two out of every three men was indeed serious, but at that time (1931) the mechanical loading of all bituminous coal mined extended only over 13.1 per cent of the total tonnage.

Since then the steadily and rapidly increasing mechanization of mines fully warranted the concern expressed by Mr. John L. Lewis in 1923 and further emphasized the point in the Appalachian Wage Agreement on the joint study of the effects of mechanization. This clause was again incorporated in the 1939 Appalachian Wage Agreement, but so far the operators have taken no steps to fulfill their obligation of the *joint* study.

Consequently the Engineering Department of the United Mine Workers of America has carried on the study unaided and against the obstacles or non-cooperation and disregard of the contractual agreement. Its study covered 204 mines in the Appalachian Region, and since no factual data were available for the fully mechanized mines where union check weighmen do not keep production records, the findings of necessity are understatements. Yet the comparison of the United Mine Workers' computations of their field studies differ from the official records of the Bureau of Mines by only a fraction of one per cent, showing that 78,140 miners are displaced due to increased productivity of labor alone.

¹ Quoted from "Labor Agreements in the Coal Mines," by Louis Bloch, 1931, p. 187.

While the Bureau of Mines statistics of productivity of labor lumped together all forms of mechanical loading, methods, and equipment underground with hand loading, the United Mine Workers data clearly differentiates the labor-eliminating effects of each of the principal types of loading equipment as well as the effect of mechanization on speed up of hand work.

This detailed study indicates that with the use of mobile loading machines two-thirds of hand loaders are no longer needed to load the same tonnage as by hand, and, with all types (average) of conveyors, one-third of the jobs is eliminated.

Since the coal loaders constitute the most numerous class of mine labor, the devastating effects of such mechanization on employment is evident.

Yet the introduction of mechanical loading equipment affects the method of mining in many other respects. Thus, *loading coal on conveyors*, whether by hand or automatically, reduces the work of laying tracks from the loading point to the point where these conveyors discharge coal into cars. In some mines the so-called "face" conveyors discharge coal not in cars but on gathering conveyors, and these in turn feed the main conveyors that bring the coal to the surface, totally eliminating all jobs of track laying, maintenance, switching, locomotive crews, and repair. This method makes unnecessary such jobs as trip riders, spraggers, car repair men, etc., and provides employment for a much smaller number of men to take care of conveyors at the loading point and for maintenance.

With the old type of *mobile loaders* tracks were necessary, but more recent models of these machines are mounted on the caterpillar track-laying tractors, eliminating the work of trackmen, etc. Later development has introduced rubber-tired machines for drilling holes (Sullivan) and so-called shuttle-cars which are automatically loaded by mobile loaders or self-loading conveyors, and deliver and discharge coal on the main transport belt or on a main haulage train. A number of completely trackless mines are now in operation in different parts of the country.

With such technological changes the output per man per day has risen to an unprecedented high. A man on the loading crew in some West Virginia mines handles up to 40 tons per shift. A recent account in "Coal Age" (April 1940, p. 63) describes a mine in Logan County, West Virginia, where, working in a 40-inch seam of coal and removing 14 inches of impurities (rash and draw-slate), performance reached 13.2 tons per man per shift underground.

To further expedite the work of men as well as to improve the quality of coal as to size and to save on time, ventilation, and safety measures, a new technique of blasting is being introduced.

While the Bureau of Mines has spent many years and a huge sum of money on testing explosives and prescribing "permissible" practice, powder and dynamite are being slowly replaced by liquid carbon dioxide (cardox) and hydraulic breaking units. By rapid expansion of liquefied gas, coal is broken into larger fragments without emission of flame or noxious gases. In hydraulic breaking, rubber tubes 3 to 7 feet long are encased in protective steel braiding and expanded by oil pumps to the pressure of 2,000 pounds per square inch. This tube is inserted into a drilled hole and, when expanded, breaks the coal without shock or jar.

With resulting increases of labor productivity the cumulative effects of new technology in coal mining, besides its direct result of disemploying superfluous men, is evident in several other respects:

First of all, the nature of mechanized mining calls for greater strain, both muscular and nervous. The machine must run without interruption. It creates noise, it demands constant attention, and it calls for prompt adjustments and movements to avoid damage or personal injury.

Because the employers realize this added intensity they seek to eliminate the older men of greater experience. Mr. Frank E. Christopher, president of the coal company bearing his name, recently told the American Mining Congress that "mechanization of coal mines calls for a higher type of worker in industry".

Second, as the productivity of labor rose tremendously in mechanized operations, the payment by the hour, irrespective of the output of a man, took the place of the piece-rate or payment per ton basis.

Thus the labor cost per ton went down approximately 45 cents per ton in mechanized mining, but part of the saving on the payroll went to the manufacturers of equipment as payment for machines, patents, rights, supplies, etc.

Third, the labor employed in building mining machines does not equal that displaced by machines. This is obvious as otherwise the investment would hold little or no incentive for the operators. As a matter of fact, a mobile loading machine costing \$10,000 requires not over 16,000 man-hours to build it. Yet this machine eliminates the employment of some 12 miners for the life of the machine. Thus in 10 years 168,000 man-hours are rendered idle as against 16,000 engaged

in the production of a machine. A *net loss* of employment is therefore equal to 152,000 man-hours per machine. With the average pay of \$5.60 per day for mine labor, the net loss of purchasing power is thus equal to \$121,000 for the life of the machine.

Fourth, the increased hazards to life and limb are created by the fact that loading machines and conveyors produce deafening noise, drowning all sounds of warning as the roof or coal is "working" and ready to fall. Accidents due to falls of roof and coal constitute some 60 per cent of total mine accidents. Another source of mine hazards is the fact that with no illumination in the working place save a dim cap light (which is sometimes obstructed by coal dust to such an extent that a man has to touch his buddy before he can see his lamp), working around fast-moving, *unprotected* machine parts is by no means safe. Furthermore, as most of the mining machinery is electrically driven, the electric cables, trolley wires, etc. create an additional hazard of explosion. A recent report of the Bureau of Mines on the Bartley Mine explosion said, "While hand loading methods may not be as efficient as the conveyor used in this mine, there is no doubt that hand loading would be safer, especially in a mine as dangerously gassy and dusty as this one * * *. The operation of numerous pieces of electrical equipment * * * is too great a risk to take in extremely gassy mines".

Of all forms of mechanization strip mining has the lowest labor content per ton of coal produced. Essentially it consists of removing the top soil and the rest of the so-called overburden to expose the coal deposits close to the surface. This work is done by large steam or electric shovels and the top soil together with the under soil is mixed and thrown promiscuously in heaps, thus destroying farm and forest land for centuries. Then the exposed coal is similarly removed from the open pit by steam shovels, loaded into the cars or trucks, and delivered to washeries for preparation.

The tonnage of coal thus mined increased between 1923 and 1934 by 9,000,000 tons, while employment increased only by 360 men. Within the last 15 years the expanded strip operations have displaced 19,550 miners, computed on the basis of labor requirements for the average deep mining. Thus, besides the great destruction of employment opportunities, strip mining destroys thousands and thousands of acres of fertile land. With proper methods of mining, however, not only the reclamation of land is feasible, but the employment of a larger number of men is claimed not to increase the cost of operation (Edward O. Keator method).

The *economic consequences* of such changed technique in mining are grave and far-reaching. With 78,000 men who lost their jobs in mines due to mechanization within 15 years, and with a total of 187,000 men displaced by all forms of changed technology, the industry and the Nation is faced with a problem of what to do with these men and their dependents—a total of well over 1,000,000 people.

One Director of Personnel of a typical coal company wrote to us: "We mine bituminous coal and employ 6,000 men. When we are fully mechanized we will have laid off about 1,000 men. I realize that the general thought is that these men will be employed in other industries as there will be more men employed in the manufacturing of these machines. But, to start with, this type of labor and the age of these men will make it practically impossible for them to even do this type of work, and besides the automobile and steel plants and machine shops are reducing their personnel and have the same problem. Industry is using the best talent and research for improving its machinery so as to lower their costs and in many instances to just maintain their present business. Of course, no corporation can afford to maintain these extra men, and if industry doesn't take care of these men the government must—and in the end the industry must pay for this in the way of taxes.

"These men cannot go "Out West" because there is no "West" any more. There is plenty of land on which these men could raise everything they need for themselves and their families, but a bricklayer today earns more in an hour than a farmer does in 12 hours.

"It is estimated that there are 9,000,000 people unemployed right now. It is very difficult to give any specific plan as to how we are going to keep labor employed while we modernize our plants. Man created the machine to be his servant, but sometimes I feel that the man becomes the servant of the machine. I know many people say "We will discover new industries". For instance, what will they be? Should industry give more attention to the men replaced by machinery or should that be government's responsibility?"

The United Mine Workers of America have favored the introduction of a 6-hour day, 30-hour week, with 200 days a year of guaranteed work ever since Mr. John L. Lewis proposed this measure at the 1933 Bituminous Coal Code hearings ("Brief Supporting General Coal Code", John L. Lewis, United Mine Workers Journal, September 15, 1933, p. 9).

And at its next convention the Resolutions Committee of the United Mine Workers of America pointed out that the introduction of machinery had "brought grave economic problems", and proposed "rather than object to mechanization of industry * * * to devote our efforts toward the shorter work day and work week".

When the 7-hour day, 35-hour week was finally secured, it was obvious that this measure was no longer adequate to absorb the technological displacement, and again at the wage negotiations in April 1939 the 30-hour week was sought, but without success.

Miners themselves, rather than see their neighbors and their children starve, frequently demand that local management reduce the number of working days for all instead of laying off completely the men whose jobs are eliminated by machines. "Work together, starve together" seems to be a motto in most of the mining camps. And the work for 2 or 3 days a week instead of 5 is frequent in many localities. The United Mine Workers of America exonerates from the payment of dues those members who work 5 or less days a month.

In other words, in such closely knit and mutually supporting communities as we find among miners, disemployment appears in two forms: *direct* displacement by technology and *indirect* underemployment created by the sharing of unemployment. How great is this indirect disemployment is difficult to estimate, but it is certain that it is at least half as large as the direct disemployment; that is, it affects not less than 40,000 families.

The economic plight of both of these groups injured by mechanization is further aggravated by their economic dependence and frequent indebtedness to the former employer. This situation gives rise to two dastardly abuses: the high cost of goods in company stores and the exchange rate of the company's scrip.

A group of photographs taken from the files of the Farm Security Administration, Federal Works Agency, and of our Engineering Department portray the dismal consequences of technology in its lop-sided application. Destitution inadequately stayed off by the food distributed by the Federal Surplus Commodity or meager WPA pay checks on one side and the scores of ghost towns with business blocks delapidated, stores and banks closed on the other.

In Illinois, where mechanization of mines is far advanced, WPA conducted a census in three counties: Williamson, Saline, and Franklin. It was found that "a large part of the working population is completely stranded * * * Coal miners constitute the great bulk of the worker population * * * Mine operators have mechanized the loading of coal to the point where thousands of hand loaders have been eliminated * * * Employment in the coal mines has declined much more than has coal production, and the decline in employment opportunities in the mines is so pronounced that a large part of the worker population is permanently unemployed * * *"

One of the most telling effects of mechanization was recorded in the town of West Frankfort, Illinois. In 1930 the population of West Frankfort was 14,683; in 1939 it was 12,733—a decline of 13 per cent. During 1926 the average output per man-day of the town's 6,000 mine workers was 5.46 tons. By 1937 efficiency increased so that one man working one day produced 8.91 tons. An increase of 63.2 per cent.

"To equal the all-time record of coal production West Frankfort operators need to rehire only 700 men of the 3,000 miners displaced."

Another case is reported at Ziegler, Illinois. "At the time of the census (December 11-17, 1938) there were 3,017 persons living in Ziegler. * * * 774 of them were engaged in private employment, either in the service industries or at the mines * * * 269 persons were on WPA, NYA, or in CCC camps * * * 107 persons were without work of any kind * * * Thus a total of one-third of all Ziegler workers were without private employment during the census week. The full gravity of the situation will be realized when it is remembered that these figures show unemployment in one of the most active coal towns in Illinois during the peak of the year's activity." (Social Security Board, Technical Publications Digest, April 4, 1940, pp. 1, 9, 11.)

In West Virginia the district north of Morgantown (Scott's Run) and the southern part of the State (Logan County) are perhaps even more desperately hit. A special report prepared by the National Research Project (WPA) describing the plight brought in by machines is so shocking that it is not even released for publication.

In Pennsylvania both central Pennsylvania coal fields and the anthracite region offer many similar exhibits of deterioration, ghost towns, and population wholly without economic background.

With such and similar ghastly results of mechanization introduced without regard to social and economic consequences, the question arises whether the limit

of mine mechanization and resulting disemployment is in sight. To that query the answer is an emphatic NO.

With only 25 per cent of the underground coal loaded mechanically and with immediate possibility of using labor-saving equipment in mining more than half of the coal output, the mechanization of loading did not reach the midstream. Considering that in 1935 only 13.5 per cent of coal tonnage was mechanically loaded and in 1939 25 per cent was so loaded, we may expect within the next five years to double the mechanical tonnage. This would throw out of employment some 80,000 more mine employees.

This estimate takes into account merely the *existing state of technique* and projects it into the future. Yet we are reasonably sure that further steps in technology will be of even more drastic nature. Recent reports indicate the successful operation of coal mines on a wholly different basis. In Russia, for example, we are informed that some mines are sealed and set afire, which is maintained by a regulated supply of air and steam to produce "water gas" underground. This gas is then cooled and purified in the scrubbers and piped to distant points of consumption at a cost said to be one-fourth of the cost of gas generated from the mined coal. Such a process requires indeed a very small crew of gas workers on the surface, thus virtually eliminating all mine labor as such.

* * * * *

From this sketchy review of technological changes in bituminous deep coal mining, certain general observations are in order. Essentially there are two kinds of inventions:

The *first* kind is the discovery of some fundamental principle upon which the new technology is later developed. Discoveries of Faraday, Clerk Maxwell, Guy Lussac, Roentgen, Marconi, and others gave us new technologies and new industries—electrical, liquefaction of gases, refrigeration, X-ray, wireless, radio, etc.

The *second* kind of discoveries consist of the application of the already discovered principles to the technology of production, such as design of labor-saving equipment, improvements of processes and other forms of inventions comprising the body of technological improvements.

The applied technological developments with which we are here concerned fall into four main groups:

1. Developments increasing productivity of labor, leading to disemployment;
2. Developments leading to intensification of labor and resulting in greater strain and hazards to workers;
3. Developments eliminating unnecessary fatigue and hazards;
4. Improvements in the quality of the product itself.

In the coal industry we readily find all of these types.

Mechanization of mines clearly falls into the first two classifications resulting in both disemployment and increased hazards. Use of non-explosive means for breaking coal belongs in the third group, while such technical processes and equipment as are used for dedusting of coal, washing, sizing, preparation, packaging, by-product extraction, etc. are clearly serving to improve the quality of the product.

From a purely engineering standpoint the coal industry has ample opportunities for economic resurrection:

1. Reduction of accidents, averaging 1,800 fatalities and 73,000 non-fatal injuries would give a saving of upward of 10 cents per ton of coal mined—some \$40,000,000 annually.

2. Multiple production of coal by-products, liquefaction, etc. will not only reduce the freight charges, now about equalling the cost of coal, but will also help to recapture the market lost to petroleum and natural gas because of a higher state of technology in these competing industries. This technique can re-employ a greater part of the 40,000 men disemployed by the use of substitute fuels.

Against this last possibility the fact that the coal industry is in a weak financial position strongly mitigates. Indeed bituminous coal industry consists of a large number of small concerns, notorious for their economic weakness—the largest unit produces less than 3 per cent of the total annual tonnage.

It might be presumptuous at this point to indicate the general theory of unemployment of which the coal industry is but a special case. The operating economy is attained by the transfer of a portion of the labor cost to fixed charges account (depreciation, insurance, obsolescence, interest and upkeep). While through the introduction of automatic machines a portion of the fixed charges on labor-saving equipment goes to payrolls in other industries (capital goods), it is much smaller than the portion of the direct labor cost eliminated by the labor-saving devices.

Therefore, the net economy in production may appear either in the dividends of the industry or in the reduced price of the product.

But the economy attained by the reduction of labor costs (direct labor and capital goods industry labor) reduces total payroll and consequently the purchasing power of the wage earners shrinks.

If the reduction of selling price be as great as the reduction of payrolls, the industry remains stagnant.

If the reduction of selling price is *not* as great as the saving on the payroll, the remaining purchasing power becomes inadequate to consume the full output of industrial products, and industry shivers.

Consequently, the money saved on labor cost cannot be reinvested into expansion of industry as there is no corresponding expansion of consumers' demand.

The special case of the coal industry differs from the general case insofar as the coal is an inelastic commodity and no amount of advertising can create a desire to overheat a house, run trains twice the distance to their destination, or otherwise consume more coal. Hence, no decrease in price could stimulate consumption to any appreciable degree, particularly when the competing fuels are already sold below the cost of production—fuel and gas oil being subsidized by overpriced gasoline. The saving on coal miners' payrolls through technological increase of labor productivity reduces the purchasing power of wage earners of this industry to such an extent that it seriously affects all consumer goods industries which are gradually losing the market among the 3,000,000 members of the families of coal miners. Further reduction of miners' purchasing power is being made by means of company stores and camp commissaries often trading at greatly advanced prices (up to 40 and more percent), or making unscrupulous profit on the issue of tokens or scrip money with average discount of some 25 percent. This excessive price increase or discount on the scrip totals well over \$130,000,000 on the volume of business carried annually by the National Industrial Stores Association.

The conclusion is therefore inescapable that the solution to the disemployment problem in the coal industry cannot be attained as long as the employees do not fully participate in the financial advantages of new technology.

TECHNOLOGICAL UNEMPLOYMENT AND DECENTRALIZATION IN THE RUBBER INDUSTRY

Statement of Thomas F. Burns, Vice-President of the United States Rubber Workers of America

The rubber industry is one which has been characterized during recent years by tremendous technological gains and increased value for the consumer. Unfortunately, this progress has resulted, for many of those depending on the rubber industry for their livelihood, not in improved, but in worse conditions.

The workers employed in this industry and the union which represents them, the United Rubber Workers of America, have been facing for the past few years the problem of technological unemployment—the problem of thousands of skilled and able-bodied workers who have been driven from the rubber industry. The issue of decentralization looms large in this story of loss of jobs in the rubber industry.

Employing 149,148 workers in 1929, this industry in 1939 employed only about 113,800 workers. (Figures from U. S. Census of Manufactures and U. S. Bureau of Labor Statistics.)

What has happened to the jobs of these 35,000 American workers? An examination of developments in the tire and tube branch of the industry will tell part of the story.

Back in 1923, approximately 74,000 workers were employed in the tire and tube industry. (U. S. Census of Manufactures figures.) Some 45,259,000 tires were produced in that year. (Figure from *Survey of Current Business*, U. S. Dep't. of Commerce, May, 1939.) In 1939, about 57,078,000 tires were produced. (Figure from *Rubber Age*, February, 1940.) But in 1939, only 52,100 workers were employed in the rubber industry. (Estimate by Bureau of Labor Statistics.) In other words, production increased some 26 percent, but employment fell by about 30 percent.

The extent of speed-up and technological advance in the tire industry is suggested by one representative tire plant. This plant was built in 1918. It was designed at that time to employ a maximum of 10,000, and to produce 10,000 tires a day. In 1939, that plant employed 6,000, and produced an average of 36,000 tires a day. From 1 tire per man in a day, to 6 tires per man—that is the kind of progress we have been seeing in the rubber industry.

General figures for the industry show this to be no isolated example of increased productivity. Figures for the tire and tube industry issued by the National Research Project of WPA, give the most reliable estimate of increased productivity here. Because the National Research Project determines production levels on the realistic basis of the number of pounds of tires and tubes turned out, rather than on the absolute number of tires or tubes, a fuller picture is given of value created for the consumer. Because they do not include mechanical goods production of large Akron plants in the tire and tube total, as the Census of Manufactures does, National Research Project statisticians have given a much clearer picture of developments in our industry, than any other economic authority.

These figures show productivity per man-hour in the tire industry rising from an index of 46.5 in 1921 to 100 in 1929, and 200.3 in 1938. That is, man-hour productivity increased by over 300 percent between 1921 and 1939, and by some 100 percent between 1929 and 1938.

The sharpest increases have come since the 1929 depression. The biggest yearly increase was in the year 1931, when man-hour productivity jumped 18 points, or some 13 percent. We have statistical proof here of the belief of many rubber workers that speed-up, etc., is pushed through when people are scared about losing their jobs, and are, therefore, less inclined to resist the change; and that rationalization coming in most intense form just as unemployment is deepening helps, in turn, to intensify the unemployment crisis.

The preliminary figure for 1939 indicates an increase in man-hour productivity which almost touched that of 1931, namely, an increase of 1939 of 12.1 percent. This means that in the one year 1939, roughly 1 out of every 8 tire workers were rationalized out of the factories.

The National Research Project figures further reveal that in 1938 63.5 percent of 1929 tire production was obtained with 31.7 percent of 1929 man-hours, and that in spite of decreased hours per employed tire worker, output per wage earner rose from an index of 46.9 in 1921 to 100 in 1929, to 145.6 in 1937, and 132.6 in 1938 when very short time was general in the tire shops.

In 1937, with a production level of 93.3 (1929=100), employment was only 64.1, and man-hours worked, 45.4. It would be fair from this to estimate that even with 1929 levels of production, the tire and tube industry can absorb only about 50 percent of 1929 hours of labor.

This is what speed-up and technological change mean in statistics. What they mean in practice, rubber workers have learned very well. They know that this level of efficiency has been obtained not only through the introduction of new machinery and improved methods, but through an intensification of the physical and nervous demands upon the worker.

POSSIBLE SOLUTIONS

In glossing over the effects of speed-up and technological change in employment, certain compensating factors are sometimes referred to, such as: (1) the development of new branches of the industry; (2) an increase in demand for products manufactured at lower prices.

Figures for the development of what is known as the "other rubber goods" industry since 1929 indicate that diversification and the development of new products will not solve the problem which we are facing in the rubber industry. Other rubber goods include all products other than tires and tubes. In spite of the fact that there has been some diversification in the production of other rubber goods since 1929, with new products entering the market, total man-hours for that branch of the industry fell from a total of 226,013,000 in 1929 to a total of 121,800,000 in 1938. Output per man-hour increased from 1929 to 1937 from 100 to 126.3, with a fall in man-hours of 100 to 73.8. (1937 is the most recent year for which production figures in this branch of the industry have been calculated.)

Diversification and new production, in other words, has fallen very short of taking up the slack caused by speed-up and technological change. In spite of the fact that rubber consumption in long tons, according to the *Wall Street Journal* of January 16, 1940, stood at an all-time high in 1939 of 577,591; employment in the entire industry in 1939 was 12.2 percent under 1937 and 23.7 percent under

1929. Consumption of crude rubber, on the other hand, had gone up 6.2 percent over 1937 and 23.6 percent over 1929.

New products have not solved and will not solve the problem of technological unemployment in the rubber industry, nor is an expansion of the market for rubber goods likely to be stimulated by lower unit prices. For tires and tubes in particular, the market is limited very definitely by the usage of motor vehicles. It is doubtful whether even a 50 percent cut in the price of tires would increase to any considerable degree the sales of tires and tubes. Those sales are definitely tied down to the level of motor vehicle utilization.

One reservation to the last statement should be made. Technological improvements in tires and tubes have increased tremendously their average life expectancy. For that reason, although there has been a tremendous increase in motor vehicle mileage since the early 20's, there has been no appreciable increase in the number of tires and tubes sold.

A comparison of gasoline consumption with tire shipments will indicate the truth of this statement. Gas consumption increased about 43 percent between 1929 and 1938, while tire shipments decreased 31.8 percent in this same period. (Basic figures from U. S. Dep't of Commerce publications.)

It is clear from these figures that technological improvements in the tire itself have more than compensated for any increase in motor vehicle mileage in recent years.

Only one force operating to preserve employment can be pointed out in the rubber industry, and that is the organized labor movement. Organized labor in the rubber industry, has, by its efforts to maintain a shorter work day at a decent wage, saved tens of thousands of rubber workers as solvent members of their respective communities.

In 1929, for instance, the average tire worker worked 44.2 hours per week to make a weekly wage of \$29.95. In 1939, the average tire worker had a weekly income of \$33.36, and worked 35 hours.

The work of the union in making it possible for workers to be retained in the industry at their normal or somewhat increased wage, in spite of reduced man-hours, should be made clear by this evidence. Further verification of the union's contribution is seen in the contrast between man-hours worked and total employment in the rubber tire and tube industry, as stated by the National Research Project. In 1938, for instance, man-hours worked had fallen 68.3 percent since 1929, whereas employment had fallen 52.1 percent. For the industry as a whole, employment fell only 32.6 percent between 1929 and 1938, whereas man-hours worked fell 54.4 percent. If employment had fallen as steeply as man-hours, only some 68,000 rubber workers would have been employed in 1938, in contrast to the 100,482 who were actually employed in that year.

In other words, some 32,000 jobs for rubber workers were saved by the union's policy of shorter hours and higher wages.

It is clearly recognized by the URWA, however, that action beyond its power, or the power of any single union, must be taken, if employment of a large section of the rubber industry's labor force is to continue. This problem is one which we share with all forward-looking agencies of government. It is one which strikes close to the roots of our national well-being. Action to solve this problem of unemployment in our country is the most pressing need of the day.

SOME RECENT DEVELOPMENTS

Something should be said about the methods which have been employed in our industry to bring about the results outlined above. For those who are interested in an exhaustive treatment of this subject, Mr. Boris Stern's *Labor Productivity in the Automobile Tire Industry*, Bulletin of the U. S. Bureau of Labor Statistics No. 585, should be recommended. Mr. Stern has analyzed and laid out very fully and clearly the changes in the tire industry which have resulted in its tremendously increased productivity. Mr. Stern shows that increased productivity in the tire industry is due to the "so-called evolutionary small changes in production", and that this process goes on "quite irrespective of the trend in the total production", and is, in fact, swiftest in years of depression.

Below are just a few examples of what has been going on in the industry during the past few years. Though necessarily incomplete, these examples will indicate what is behind the National Research Project figures quoted above.

1. The method of operating calendars in a Pennsylvania tire plant was changed last year. It resulted in a 33 percent cut in the amount of labor required per unit of production.

2. In 1938, in one Akron tire plant, a change from the core to the flat top crown method of truck tire building, with certain other minor modifications in the operation, resulted in the elimination of 150 jobs in a department previously employing 525.

3. Another Akron plant recently changed over from the pot heater method of vulcanizing tires, to the automatic watch case mold. The labor cost of curing 100 tires (600X16) was reduced by this change from \$13.50 to \$6.00. Man-hour productivity was increased from 9.9 tires to 21.3 tires. Watch case molds are now operating or are being introduced in all efficient plants.

4. In the compound and mill room of another Akron plant, production was increased by 15 percent in 1938, without any changes in machinery or methods of operation. Many changes have taken place in machinery and methods of operations, which, without basically changing the process, are intended simply to secure the more efficient utilization of labor.

5. An example of this is the conveyor method of building tires. Ordinarily, the tire builder works at a single machine, performing all the necessary operations for building a tire. By the conveyor method of building tires, however, the individual tire builder performs only one part of the whole operation, on a number of machines. Tire machines are fixed on either a rotary or straight line conveyor, and the individual worker is responsible for performing continuously only one of the numerous operations involved in tire building.

Information from our local unions indicates that this method, although it involves no basic change whatever in the construction of the tire, has increased tire builders' productivity by at least 43 percent. This method, with its much intensified demands on the nervous energy and endurance of the workers, is being introduced in nearly all the more efficient tire plants.

6. Two changes in tire building machines in the Goodyear Akron plant since 1934 have increased a tire builder's production from about 38 per 6-hour day to around 92, an increase of over 2½ times in four years.

7. An example of the increased productivity through simple intensification of effort is to be found in a recent episode in the curing room of the Firestone Tire and Rubber Co. There, in October, 1938, the time for curing tires was shortened from 90 to 60 minutes. This made it possible for the workers to increase the number of heats cured per 6-hour shift considerably. Employees in that department were informed one morning as they came into work that they were expected to increase the number of heats they cured on their shift from 54 to 67. They were informed that unless they did this, their work would be moved to Firestone plants outside of Akron.

At that time, a considerable propaganda campaign on the issue of decentralization had been developed at the instigation of the companies, which coincided with the recession and layoffs of 1938. In this situation, this group of Firestone employees refused to accept the advice of union committeemen, and insisted on complying with the company's demands.

For some days they succeeded in meeting the new level of production, that is, 67 heats per shift, but in subsequent weeks, they found it physically impossible to meet the increased production requirements. As a consequence, daily wages were considerably reduced. It may be added here that work in the pit is recognized as one of the heaviest and most disagreeable jobs in the rubber industry. Temperatures in this department range up to 130 degrees.

It will be understood what constant labor without a minute's respite under these conditions meant to the welfare and health of the rubber workers. These Firestone employees reported to local union officials that frequently it was impossible for them to eat a meal until they had had a number of hours rest following shift end.

Examples given so far are drawn from a great number available in the tire and tube industry. They are typical, also, of situations in the other rubber goods industry.

8. For instance, in one highly efficient plant, manufacturing mats for automobiles and other mechanical goods, a number of changes were made in the mill-room during 1936. As a result, a 30 percent increase in man-hour labor productivity was obtained, and the working force of that department proportionately reduced.

9. In the compound room of the same plant, a similar increase in the man-hour productivity was obtained, simply by demanding increased effort from the workers employed. Subsequent action by the local union in defense of the health of these employees brought some reduction in the total output expected, although they were still considerably speeded up over previous levels.

10. And, to give one final example, in a boot and shoe plant, where the local union has no direct speed-up to report, a change in the method of construction of shoes took place. This resulted in the displacement of 150 workers out of 500 formerly employed in the building department.

WAGE INCENTIVE SYSTEMS

The rubber industry, like most mass production industries at the present time uses a number of different wage incentive systems. It is not our purpose to go into any exhaustive analysis of the complexities of these systems. There are a number of points in connection with them, however, which bear directly upon this inquiry.

It will be agreed, in the first place, that the underlying purpose of the wage incentive systems—time study, Bedaux, etc., is to increase man-hour labor productivity, without further investment in productive equipment or basic change in productive methods. All rubber workers know what these systems have meant to their working conditions. As the plans are applied generally, a base is determined upon the productive record of the average employee on a given operation. He is then offered a series of bonuses upon production exceeding the base rate established. He is persuaded and induced by every means to increase his production, and he is instructed by time study experts upon more efficient methods of attaining this end.

Rubber workers have found, of course, that as their general level of production increases, the base or minimum expected of them is likewise increased. They are forced, therefore, to put forth more and more intensive efforts, in order to maintain a stable level of hourly earnings.

Champions of these wage incentive schemes assure us that when properly applied, they result in no greater physical demands upon the worker. Speaking from the almost universal experience of the rubber workers, however, we testify that the intensity and speed of the physical effort involved has definitely been increased with the introduction of wage incentive systems throughout the rubber industry. Whether this increase in physical effort is to be attributed to an improper method of applying wage incentive systems, or to the very nature of the system itself, we are not in a position to say. Whatever may have been the cause, the result in increased effort for rubber workers is clearly apparent.

On this general question of new machinery and intensified physical effort, we quote from a statement made by Mr. George Dirks, in his pamphlet entitled *Time Study in a Union Shop*. Mr. Dirks is manager of the Time Study and Standards Department of the Service Divisions of the B. F. Goodrich Co. In commenting on this problem arising from the creation of "surplus help," Mr. Dirks has a number of interesting points to make. (Surplus help, of course, is help made surplus by new equipment and intensified methods of work.)

"1. Consideration should be given to the handling of surplus help previous to the installation of the new equipment. Transfers of course to other operations should be made whenever possible. When layoffs are necessary they should all be made before the new equipment is installed. By handling the problem in this way the layoff can be handled as a separate and distinct problem and not made a part of the problem of introducing the new equipment to the remaining crew.

"2. The hourly earnings of the workmen in the remaining crew should not be reduced. Often it is found that by conscientious attention to details during the design stage of the new equipment, ways and means are found whereby the man power as well as the machine can be arranged for maximum usefulness and the hourly earnings of the men thereby actually increased.

"3. Job improvements affecting a large number of employees can best be handled during periods of low production. Later, when production increases, it often is found that the available working force can adequately handle the increased production.

"4. Large projects can sometimes be handled on a so-called piece meal basis. That is, by installing certain self-contained units one at a time, and then working out the individual problems on each unit. By handling the problem in this gradual way, the possibilities of the Corporation absorbing some of the surplus workers are enhanced, particularly if the changes occur during a period of rising activity."

Mr. Dirks deserves congratulations on his very clever methods of sugar-coating for rubber workers the bitter pill of technological displacement. But we fear that methods such as his will not help us very much in approaching the basic problems of our industry, and our economy as a whole. Concealing the effects of new machinery and intensified methods of work will not give jobs to the unemployed.

QUESTION OF DECENTRALIZATION

The tremendous drive toward increased productivity in the rubber industry is related very closely to recent developments in the shifting of production. Experience in other industries has shown that where an industry has operated for a number of years in a given locality, certain definite standards of wages and effort are established.

The textile industry, in particular, has shown that where new techniques come in, bringing new efforts to intensify labor, there is a tendency to shift production to new localities, where a raw labor supply will more likely yield to the demands of industry.

There are often other factors in cheaper costs. Lower freight rates, which we understand have sometimes taken the form of differentials favoring particular localities, lower taxes, cheaper power, and control over public officials frequently come into the picture.

To understand the full implications of developments in shifting production in the rubber industry, the strategy of decentralization must be clear. One of the most important elements in the so-called decentralization from Akron is its use as a threat against labor standards, and, indeed, general standards of living in the community.

Decentralization offers the possibility of lower costs in outside, less highly industrialized communities, and at the same time can be used as a lever against the older community, Akron, to bring down costs there. One large factor in bringing down costs is the use of machinery and new processes to increase labor productivity and lower labor costs. To be most effective in achieving lower costs for the companies, these changes must be introduced exactly as the companies want them. A union which, for instance, insists on maintaining a shorter work week and higher hourly rates, in order to alleviate unemployment resulting from increased productivity, such a union may seem to be a nuisance to the companies. Perhaps the most potent weapon which can be used to dishearten a labor group is the threat of losing jobs.

The experience of Akron, Ohio will indicate the possibilities of the power to decentralize, or to threaten to do so. This is indeed a strong weapon in the hands of employers who may choose to disregard the well-being of communities.

The rubber industry, in its history, has seen two distinct tendencies in the movement of production from state to state: (1) the early movement from New England and the East Coast to the state of Ohio, and to Akron in particular; (2) the more recent tendency toward partial decentralization of production from Akron.

In 1899, out of 36,566 rubber workers employed throughout the country, 2,677 or 7.3 percent were employed in Akron. Out of a total wage bill in the rubber industry of \$15,426,573, Akron workers received \$1,005,405, or 7 percent. (These figures are from *Rubber Industry of the United States, 1839-1939*, published by the U. S. Department of Commerce.)

By 1935, however, 64.2 percent of workers in the tire and tube industry were concentrated in the Akron industrial area. Akron rubber workers received wages of over \$78,000,000 in 1935, 69.9 percent of the United States total. (Figures from U. S. Census of Manufactures.)

The predominance of Akron in the rubber industry came with the growth of the automobile industry, with its mounting demands for pneumatic tires, in the first 20 years of this century. By 1919 Ohio, including Akron, reported 48.5 percent of the total value of production, and 40.2 percent of the total wage earners in the rubber industry. (Figures from the Department of Commerce study mentioned above.)

This tendency toward concentration in Akron continued with the rising power of the Big Three—Goodrich, Firestone and Goodyear—whose production facilities during the early 20's were almost entirely concentrated in Akron.

This tendency was strengthened, not primarily through the actual movement of production by companies from one state to another, but by the growing domination of the larger companies throughout the industry. With the development of intense competition during the late 20's, and in the depression period of the 30's, many smaller companies located outside of Akron fell by the wayside.

During the 20's, on up to 1936, productive capacities for 38,000,000 tires a year were closed down throughout the industry. (Excess capacity, in spite of this, was "almost 40 percent".) (Information from *Rubber* by Howard and Ralph Wolf, p. 464.) A large share of the wreckage took place outside of Akron. The big companies, with their tremendous financial resources, their partial command over raw material supplies, and their highly developed research and engineering staffs, were able to ride out depression conditions, intensified by bitter price wars.

The smaller companies, dependent upon the declining replacement market for all sales, were hard put to it to live through this period, especially in face of the cut-throat price wars instigated by the giants of the industry.

Even the powerful United States Rubber Co. had a narrow escape from extinction during the early 30's. All of these factors combined to produce a tendency toward concentration in Akron's more efficient plants.

The trend toward concentration is demonstrated in the decline in the number of tire and tube establishments. The number fell from 178 in 1921 to 46 in 1937. (U. S. Census of Manufactures.) We estimate that the number of tire companies in 1937 was only about 30. (*Rubber Red Book, 1937.*) (Many of the companies have several different plants, which accounts for the difference in the 2 figures.)

It has been estimated that in 1935 about 90 percent of the tire business was in the hands of the Big Four tire companies. This estimate was made by *Fortune* and published in the November, 1936 issue.

In the rubber industry as a whole we also find a high degree of concentration. In 1935, 4.3 percent of the corporations owned 80.4 percent of the assets. These figures are based on the fact that the 25 companies which had assets of \$5,000,000 or more apiece, had total assets of \$762,443,000. The remaining 553 companies, those with less than \$5,000,000 apiece in assets, had a total of \$190,369,000. (Figures from U. S. Dept. of Commerce, Bureau of Internal Revenue.)

By 1936, however, the tendency toward concentration in Akron, through the mounting power of the Big Three, was met increasingly by a counter-tendency, that of decentralization. *Business Week* for April 18, 1936, states, "Decentralization of the rubber industry, which has gone forward quietly for the past 10 years, was brought into the open last week by rubber manufacturers as a threat and a promise." The nature of that threat and promise we will refer to later.

The movement away from Akron served to diminish somewhat the level of concentration in Ohio, during the depression period previously referred to. It should be noted, however, that in the tendency away from Akron, a major part was played by the establishment of branch plants of the major rubber corporations, rather than the development of new and competitive plants.

The first move toward decentralization by the Big Three took place in 1920, with the establishment by the Goodyear Tire and Rubber Co., of a branch plant in Los Angeles, California. This plant, employing 1800 workers was established apparently to give the Goodyear savings on transportation and distribution costs.

The other major rubber companies were not long in following Goodyear's example. Firestone opened its Los Angeles plant, employing 1,700, in 1927, and Goodrich, with an employment of 750, in 1928. In 1929, at the request of Sears, Roebuck and Co., Goodyear established in Gadsden, Alabama, another tire and tube plant, employing about 1,600.

It is not without interest that during these years, also, the major rubber companies were establishing for themselves branches and subsidiaries outside of the United States. Without question, one important factor in the establishment of these foreign plants was the desire to overcome tariff barriers established over the world during the 1920's. We estimate as 10,000 the total number of jobs in the rubber industry moved out of the country by the Big Four, including U. S. Rubber, of the industry, during the 1920's. Accurate totals, however, are not available to us.

Another factor, however, in the location of foreign plants is suggested by the Goodyear plant now operating in Java, and employing approximately 750. This plant set up to give Goodyear an entry into the Japanese market, pays its tire builders at the rate of from 3 to 8 cents per hour. In this plant, and in certain others, it is probable that the desirability of low wage rates has been an important factor.

Representative of the tendency followed in the location of plants outside of the United States is the history of the Goodyear Tire and Rubber Co.'s expansion. Goodyear's plants are now located in Canada, England, Java, Australia, Argentina, Brazil and Sweden.

These plants employ, according to our estimates, the following number of workers: England, 2,696; Java, 1,217; New Toronto, Canada, 1,443; Australia, 1,226; Argentina, 997; Bowmanville, Canada, 489; Sweden and Brazil, 200 each. (The last 2 are a very rough estimate, based on newspaper reports.)

(The above estimates are based on a report of man-hours per year in Goodyear plants, published in *India Rubber World*, December, 1939, p. 68. It was assumed that 1600 hours per year represented one job in all plants. 1600 is a liberal estimate of the number of hours worked per year by Akron Goodyear employees.)

Thus, the Goodyear Co., for various reasons, decentralized not from Akron, but from America, some 8,400 jobs since 1920.

So far as its American operations are concerned, Goodyear has found it advantageous to shift part of its production outside of the main Akron plant during recent years. The establishment of the Gadsden plant in Alabama in 1929, at the request of Sears, Roebuck and Co., with which Goodyear had a contract, the taking over of the bankrupt Kelly-Springfield Tire and Rubber Co. at Cumberland, Maryland in 1935, together with the establishment of plants in Jackson, Michigan and Windsor, Vermont in 1937, and St. Mary's Ohio in 1940, have indicated a recent trend of company policy.

The Firestone Tire and Rubber Co., also, during recent years, has established branch plants outside of Akron. This development took place almost entirely within the year 1937. At that time, according to our estimate productive capacity, sufficient to employ in the neighborhood of 4,000 workers was established by Firestone in the cities of Memphis, Tennessee, Fall River, Massachusetts, and Wyandotte, Michigan. A good share of this outside productive capacity was established, apparently, to take the place of production formerly carried on at the company's main plant in Akron, Ohio. Before 1937, Firestone had established only 1 outside plant, employing 1700 workers, in Los Angeles, California.

The Goodrich Tire and Rubber Co., in the same year, established outside of Akron productive facilities to employ 750 rubber workers. A mechanical rubber goods plant in Cadillac, Michigan, and a highly efficient tire plant in Oaks, Pennsylvania were established in 1937 by this company. For 1940, the company is announcing the opening of a mechanical goods plant in Clarksville, Tennessee. In 1928, Goodrich established a tire plant in Los Angeles, to employ 750, and in 1929 took over the Hood Rubber plant in Watertown, Massachusetts, for the employment (at capacity) of 4,500.

These facts will indicate what *Business Week* was writing of when it described decentralization as a threat and a promise. The threat was to Akron, and its industrial employees, the promise to any community willing to meet demands laid down by the rubber corporations. Since decentralization has been made a prominent issue, through the publicity of the rubber companies, the certain so-called "community agencies," analysis of the causes and effects of these moves is of considerable importance.

COMMUNITY BLACKMAIL

On February 28, 1936, Mr. L. Hurley of the Goodyear Tire and Rubber Company wrote to E. S. Cowdrick of the Special Conference Committee concerning the strike then in progress at Goodyear's Akron plants:

"While McGrady says he has a plan, it is very similar to the one he put in down at Toledo, and as you know, this has not put a permanent end to this sort of labor difficulties. Just off the record, you know that General Motors is doing everything possible to move all of their operations out of Toledo, and an agreement to a plan such as this would mean that we would eventually move our operations to other parts of the country."

This was not the first time the threat of decentralization had been used in an attempt by the Goodyear Company to wring concessions from the citizens and workers of Akron.

Since the emergence of the union as an active force in Akron rubber plants, the threat of decentralization has been thrown constantly at rubber workers and the community.

For the most part, the companies have been content to allow the proclamations of disaster to be issued by various so-called "citizens' committees." For a number of months in late 1937 and 1938, the Greater Akron Association paid for regular radio programs and newspaper ads, in which the cupidity of the rubber workers and the CIO was held responsible for making Akron a "ghost town". The Akron Chamber of Commerce also prophesied civic disaster.

Although it was first to open fire with the decentralization propaganda, Goodyear has not carried recent decentralization so far as at least one other big company, the Firestone Tire and Rubber Co. The two Goodyear plants established since 1936 at Jackson, Michigan and Windsor, Vermont employ an approximate total of 1,845. Firestone, since 1936, has set up plants at Fall River, Massachusetts, Memphis, Tennessee, and Wyandotte, Michigan, to employ a total of about 4,000.

Off-the-record gossip from sources close to rubber company management is that most of the decentralization planned since 1929 by the big tire companies is completed. It was the relative prosperity of 1936, rather than excessive union demands, which stimulated the burst of decentralization that saw close to 5,000 new jobs established outside of Akron.

Only with tire sales up, the industry stabilized through an armistice to price wars, and profits increasing, did the big companies feel justified in launching on their program of decentralization.

Recent investments by Goodyear and Firestone for the "modernization" of their Akron plants indicate that major steps in the direction of more decentralization are not to be undertaken in the immediate future.

The extent to which decentralization has taken place from Akron is difficult to determine in the atmosphere of gossip and hysteria which has attended the moves.

In 1929, 61.4 percent of tire workers, or 51,135 workers, were employed in Akron; in 1938, 49.4 percent, or 25,100. If the 1929 percentage of jobs in Akron had prevailed in 1938, the Akron 1938 employment in the tire industry would have been 29,042. This indicates that around 4,000 jobs had been decentralized from Akron since 1929. It should be remembered that this does not represent, necessarily, the movement of jobs and equipment outside of the city. Had the capacity of outside plants been utilized at top levels, and Akron allowed to absorb the full impact of the depression in the form of reduced output and employment, figures for 1938 would have little real meaning in terms of shifted productive facilities.

At any rate, it is clear that enough jobs have been moved from Akron to make rubber workers and Akron people fear the threat of decentralization.

How the B. F. Goodrich Co. attempted to use this threat in an effort to force through a heavy wage cut was shown in the spring of 1938. At that time, the company announced that competition would force it to move 5,000 jobs out of Akron unless the union agreed to reduce labor costs by taking a general wage-cut, ranging up to 17½ percent.

Following an impartial study of the company's position by a representative of the U. S. Dep't. of Labor, which failed to establish the necessity for a cut, the union rejected the company's proposal. In the meantime, various "civic groups", playing on the prospect of an income loss to the city, through a fade out of 5,000 jobs, had been bringing to bear upon the union membership intense pressure for acquiescence to the company's demands. A crowd led by the Secretary of the Chamber of Commerce, now Administrator of Unemployment Compensation for the State of Ohio, surrounded and threatened union negotiators on company property on at least one occasion during the controversy.

However, the union was able to bring its position before a large section of the public, and no violence materialized out of the whole situation.

Though subsequent movement of 400 jobs in mechanical goods production to a new plant in Clarksville, Tennessee has scarcely served to vindicate the company's threat of 5,000 jobs lost, enemies of the union in Akron still charge it with "driving jobs out of Akron." This experience demonstrates very clearly that in its power to threaten decentralization, a modern corporation may easily establish the impetus to vigilante movements threatening the law and order of an entire community.

In February, 1940, Goodrich announced plans to build a new \$70,000 factory using machinery to cost \$100,000 in Akron. This announcement coming less than 2 years after the drive to "Keep Goodrich in Akron" by lowering wages has particular significance.

The whole "strategy" of decentralization should be clear. Since 1935, the Big Three in the rubber industry have been seeking to reintroduce the 8-hour day in their Akron plants, and to drive their workers to higher and higher levels of production. Cuts in hourly rates to bring wage levels for the 8-hour day down to those prevailing for the 6-hour day, were included in the program of the companies.

The direct frontal attack to put over this program failed when Goodyear workers fought for their standard of living (and the community's) in the strike of 1936.

Taking a new course, the companies undertook a war of attrition and flank movement in 1937. In this campaign, "decentralization" was the basic munition.

By taking advantage of the general program of decentralization worked out during the early thirties, the companies covered their move into low wage areas with indictments of the union.

Objects of this propaganda were apparently:

(a) *To break the unity of employee resistance to lower standards of pay and intensified production standards.*—The outright discharge of a section of organized workers and their replacement by workers pledged against unionism would have been a clear violation of the Wagner Act. The transfer of production from organized plants to new plants where organization was rendered intensely diffi-

cult, could be expected to accomplish the same purpose, without obvious violation of the Act. Workers could be deprived of employment because of union activities without any redress under the law.

Workers in the new outside plants have accepted the speed-up, the 8-hour day, and wage levels below standard for the industry, because organization and collective bargaining have been denied them. Some examples of how this is accomplished are described below. This has made the defense of union standards difficult in Akron, Detroit and other organized sections of the industry.

Wage levels in plants set up since 1936 under the decentralization schemes of the major companies are almost without exception below the wage levels of the industry. Average hourly wages for the tire and tube industry have stood at about 96 cents in recent years, while in the other rubber goods industry 60 cents has been the average. (U. S. Bureau of Labor Statistics figures.)

At Goodyear's Gadsden tire plant, workers receive, according to reliable estimates, an average of 75 cents an hour. At Firestone's Memphis plant, 75 cents is the highest paid wage. Work for other skilled employees ranges from 54 cents to 72 cents an hour. Common labor is paid under 40 cents.

The mechanical goods plant of the Goodrich Company at Cadillac, Michigan, pays an average of 40 cents per hour, according to information which we believe to be reliable.

(b) *Further object of this decentralization, anti-union propaganda was to identify the union publicly with the evil social effects of industry's ruthless policies.*—Alleged "excesses" of the CIO were blamed for decentralization policies which were in operation 15 years ago in the rubber industry, long before labor was organized. Nation-wide publicity was given this brazen falsehood. It is used to intimidate workers all over the country, and bring the vigilante spirit to communities unfamiliar with the labor movement.

By and large, the city of Akron sympathized with the struggle of the Goodyear workers to protect their hours and wages in 1936. Decentralization scares sought to substitute antagonism and hostility in the place of this sympathy. As a result, some Akron storekeepers and businessmen were placed in the anomalous position of supporting sharp reduction in their customers' purchasing power under the threat of this social blackmail.

(c) *Another object of this propaganda was to establish private industrial control of public political power.*—In the struggle to shift production from community to community, bidding by communities is intense. Many inducements are offered. Among them, too often, is an offer of control over, or at least "cooperation" with, local governments in the interests of the company. Civil rights of the workers and local democratic institutions and processes are sacrificed to the zeal for securing "new industry."

In commenting on this issue, the Citizens' Fact Finding Movement of Georgia (Series III, No. 3, P. 13) states:

"In many cases where the wooing of outside industry has been too eager, the community has been committed in advance to a policy of maintaining a force of cheap and docile labor. Commitments of this kind have always been implied, if not verbal. The result is the effective suppression of personal rights and civil liberties in these communities."

This tendency to sacrifice civil liberties and democratic rights is not confined to any one section of the country. In St. Mary's, Ohio, the Goodyear Tire and Rubber Co. recently completed the erection of a plant for the manufacture of pliofilm and miscellaneous rubber goods. Albert M. Koch, Mayor of St. Mary's, was recently quoted in the *Akron Beacon Journal* to the following effect:

"There's a strong feeling against them (labor organizers) here, and I dread the thought of what might happen if they come in." (November 19, 1939.)

Mayor Koch's "dread" has been realized. A citizens' committee came together recently in his own office, to drive out of town AF of L organizers who had attempted to bring unionism to construction workers on the Goodyear plant.

The experience of the URWA in Gadsden, Alabama illustrates the completeness with which an industrial company may dominate a community's agencies of government. The situation is described in the reports of the hearings before the La Follette Committee. (Part 8, pp. 3002, ff.)

Examples of this kind could be endlessly multiplied from the general experience of the labor movement. It is apparent that with communities vying with each other for location of new industry, and conniving at the violation of civil liberties and the maintenance of a "docile" labor supply, the whole foundation of American democracy is imperiled.

OTHER POSSIBLE CAUSES OF DECENTRALIZATION OF THE RUBBER INDUSTRY

(1) *Decentralization may be in search of lower costs of distribution and transportation.*—This will apply, we believe, to the establishment of such plants as the Goodyear plant in Gadsden, Alabama in 1929, and to the California plants of the Big Four rubber companies. The policy, also, of such large automobile manufacturers as Ford and General Motors, with their decentralization of production, has tended to force like decentralization in the automobile tire and tube industry. Here transportation costs bulk as a major factor.

(2) *Shifting of production from less to more efficient plants has taken place to some extent in the rubber industry.*—As well as decentralization, the United States Rubber Co. offers an outstanding example of this tendency in the rubber industry. When this corporation was taken over by Du Pont interests in 1928, it was made up of a large number of plants, operating in different localities, many of them at a very low level of efficiency. In an intense effort to meet competitive costs, U. S. Rubber management was forced to close down plant after plant throughout the country, and to centralize production in its most efficient plants. In those plants, naturally, higher and higher levels of productive efficiency were obtained, with no substantial increase in the labor force.

From 1928 to 1935, 19 of the 44 plants were closed down, and production consolidated in the remaining 25. It must be noted here that the U. S. Rubber Co. made considerable efforts to secure new employment for its laid-off workers, and that older employees were partially compensated for their loss of work by dismissal pay.

(3) *Unscrupulous bidding for new industries by many communities has resulted in many serious shifts in production.*—During depression years, with the failure of industrial production to expand naturally into new territories, there has been a tremendous development in competitive bidding for the industrial production available, as we pointed out before. Without seeking to go fully into this problem, which concerns the steel, auto, textile, hosiery, shoe and other industries, we should like to give something of the experience in rubber. There we have seen various communities in the North and South seeking to entice to themselves new plants, by offering a whole range of favors and special dispensations. The presentation of free plant sites, the provision of capital for the construction of factories, absolution from payment of taxes, or special slashes in tax rates, and other special favors are offered to companies by the representatives of states or communities.

The city limits of Memphis, Tennessee, for instance, were swung around the Firestone plant established there in 1937, so as to allow the rubber company to pay the county rate, rather than the city tax rate. This made a difference between \$3.09 per thousand in the city, and 96 cents per 1,000 in the county, in favor of the company. A similar situation prevails in Gadsden, Alabama, where the Goodyear plant, having been provided with a free site, was placed outside the limits of the city. In Cumberland, Maryland, by action of the city council, the Goodyear Co. will pay no taxes until 1945.

The Goodyear plant in St. Mary's, Ohio is being built on a 21-acre farm, bought by popular subscription of \$23,000 by local citizens. In Windsor, Vermont, the machinery, capital stock, and personal buildings of the corporation are tax exempt for ten years.

The State of Mississippi has authorized local units of government to issue bonds for the erection of manufacturing plants. The Armstrong Rubber Co., of West Haven, Connecticut, has taken advantage of this offer, and has built in Natchez, Mississippi, a plant which will furnish employment to about 400. It may be added that the Armstrong Rubber Co. is not organized by any labor union, and has, nevertheless, seen fit to "decentralize".

It is assumed by the rubber companies that their choice of location for operation is a private matter, for decision according to the immediate interests of management. It must be remembered, however, that both the community and the nation have a vital interest in the economic forces determining their very life. The city of Akron is a city built for and by the rubber industry. Experiencing a rise in population from 69,000 in 1910 to 250,000 in 1930, this city has no substantial economic base outside the rubber industry. (In 1929, some 76 percent of the employed industrial workers of Summit County were tire and tube workers; total number of wage earners was 67,298, and total wages, \$107,253,929. In 1937, these totals had dropped to 52,888, and \$80,701,916. In the latter year, some 67 percent of the industrial workers were tire and tube workers.) (Figures from the U. S. Census of Manufactures.)

SOCIAL EFFECTS OF DECENTRALIZATION

Akron citizens invested from 1914 to 1929 over 97½ million dollars in homes. Without the rubber industry, the value of these homes and the value of Akron real estate would be reduced to practically nothing.

Civic improvements have been made for the rubber companies and paid for from tax money. For example, the \$1,500,000 Mogadore dam which is nearing completion was started at the insistent demand of the Goodyear Co. The company said that it would have to move some production from Akron unless its water service was improved. Early in 1938, however, long after the project had been undertaken, Mr. Litchfield, President of the Goodyear Co., blandly declared that Goodyear no longer needed the water from this dam. Large public investments, as well as rubber workers, seem to be at the mercy of rubber company whims.

Decentralization of the industry seemed to threaten disaster, therefore, to the full security of Akron's middle and commercial classes. The loss of 5,000 or more jobs to Akron would mean the loss of something like \$7,500,000 in yearly income and cash circulating through the veins of the city's economic life. In comparison to it, the social consequences of a major air raid would be incidental.

At the same time, Akron's middle class has come more and more to realize that surrender to the companies' campaign of longer hours and shorter wages would have equally disastrous results. That campaign, too, meant the loss of jobs and the loss of basic income to the community. Thus, this community seemed to be facing strangulation—loss of income through increased shifting of jobs, or through increased exploitation of its workers.

From these circumstances, it is clear that the tremendous economic power of corporations over the communities in which they operate must be subjected to some kind of regulation, for the public good. If stable community and civic enterprise is to be built up, if the investment of a lifetime of saving and endeavor is to be secured, there must be some guarantee that powerful corporations will not be allowed freely to overthrow the economic life of a community. If American society is to be stabilized, the responsibility of corporations to the community and to the nation at large must be established.

It should be clear that what we are discussing is not simply an Akron problem, that what we are interested in is not simply the welfare of Akron. The unregulated power to decentralize and shift production, without consideration of its social consequences, is a thing which threatens the security of every community and state in the nation today.

It is difficult to estimate the full social cost of speed-up and decentralization in the rubber industry upon such a city as Akron, Ohio. From January of 1938 to January of 1939, the number on WPA in Summit County increased from 8,356 to 19,876 (From WPA Administrator Roose.) Although WPA authorities have no information to give on the number of rubber workers in this group, they are generally estimated to make up the large bulk of those securing WPA employment.

By January, 1940, WPA rolls in Akron have been cut from the high point of January, 1939 to 9,919. It must be added that in January approximately 4,000 employable workers were on city relief, where they are living on a relief quota providing 4½ cents for each meal. The level of production in the rubber industry is, very roughly, equal to what it was in the middle of 1937, when 6,000 were on WPA, and only 362 employables on city relief. It would be correct, then, to estimate that in Akron there are at least 6,000 rubber workers whose jobs at present levels of production have been wiped out by the combined forces of technological advance and decentralization.

The total loss which this represents to the community is by all estimates tremendous. Even assuming the continuance of adequate WPA and city relief (a very large assumption, indeed, these days), buying power of these 6,000 employable workers is cut by more than half. Akron WPA workers receive \$57.20 a month; rubber workers, about \$140.00.

A series of interviews with a group of former rubber workers now on WPA indicates something of what this means to their standard of living, and to their buying habits. Everyone interviewed had been forced to cut their rent by 50 or 60 percent. Incidental expenses, such as entertainment, automobile travel, etc., were entirely eliminated. Expenditures for clothes of these workers and their families in the past two years averaged from \$20 to \$30, and in no case reached over \$50.

Stories presented were of unpaid doctors, grocery and insurance bills, of cars no longer operated because the rubber workers could not buy tires, and of a general reduction of living standards to the most meagre level of subsistence.

Investors in the rubber industry may look with some wonderment on the expansion of facilities, even if the ostensible reason for such expansion is to get greater "efficiency" from operations.

The rubber industry has been notorious for its excess capacity. In NRA days, the Rubber Manufacturers Association estimated by a most conservative method that there was excess capacity in the tire industry of some 37 percent in the years 1927-1933, and felt "quite confident that this information conclusively demonstrated the desirability of limiting the creation of additional productive capacity". (From *The Rubber Industry Study* put out by the NRA Division of Review.) At that time, it was estimated that the industry had to count on carrying between \$35,000,000 and \$40,000,000 in fixed assets which were idle.

We estimate that 5 tire plants built since 1933, when these remarks were made about the seriousness of excess capacity, account for capacity for about 9,500,000 more tires a year.

Investors, if the facts were revealed to them, might well join the rubber workers in looking with disfavor on the building in the name of greater efficiency of more and more plants, in an industry already overbuilt.

THE NATIONAL PROBLEM OF DECENTRALIZATION

Decentralization has brought, perhaps, certain temporary advantages to the communities in which new factories have been erected, but it has brought also, to those communities, ever-increasing speed-up in the factories, an unparalleled flouting of civil liberties, and no secure guarantee of economic welfare. It results, indeed in an economic debasement, eventually, which threatens our vaunted American standard of living.

Unrestricted decentralization is as much a threat to the new as to the old community. Gadsden, Alabama, for instance, is told by the Goodyear company union that union organization will drive jobs out of Gadsden back into Akron.

Looking at the whole problem on the national scale, it is clear that the issues have been intensified by our present economic difficulties. The failure of industry to expand in the past decade has intensified competition among communities and states for a larger and larger share of already existing production.

Autarchy has been criticized as an economic doctrine in its application to the life of modern nations at large. The idea that a nation may live outside the sweep of the world economic system has proved false. The effect of the unrestricted power to decentralize has been to establish throughout this country tendencies toward autarchy, or economic isolation, on a regional, state or even community-wide basis. Tire dealers in the South advertise, "Buy Southern Made Tires". On the other side, there is a strong tendency among Ohioans to demand Akron or Ohio made tires. This kind of sectional economic rivalry is surprising and disconcerting in our country, whose greatness has been established upon the unity and cooperative endeavor of all sections in the building of a common economic life.

Few other issues in the life of our country today seem to us more in need of investigation than this. Our experience has been but a small part of general developments. We believe that we are expressing not the interest of any single community or any single region in saying that the threat to American living standards, implicit in the power of shifting production at will, is one which requires an early and thorough investigation looking to the framing of appropriate legislation.

SOME CONCLUSIONS

We submit, in the first place, that we have no panacea to offer for the immediate solution of the problems which we have outlined. A constantly rising power of production has brought with it in our industry, as in many others, a constantly declining power of consumption. As immediate steps toward a solution of this problem which threatens the foundation of our American way of life, we have the following suggestions:

(1) The recognition of labor's contribution to the stabilization of our economy, together with continued guarantees of labor's right to organize and bargain collectively with employers. Labor alone, during the past few years of intense technological advance and unemployment, has taken steps to check this fatal tendency. We have gladly accepted the new efficiency of machines, but we have striven to maintain the yearly income of our workers, in spite of reduced hours. This, in our industry, has meant the salvation, as we estimated before, of approximately 32,000 jobs. The CIO has made a similar contribution in the country at large. We have striven to protect the communities in which we have members

against the evil results of irresponsible decentralization—but it is obvious that we cannot cope with this problem single-handed.

(2) More definite support from government agencies for the union's attempt to maintain the living standards of America's industrial workers. The legislative program of the CIO stands as the clearest expression of necessary steps for the attainment of this end, and for American economic stability, at the present time.

(3) A thorough-going investigation of the problems whose main features we have endeavored to describe. Both technological unemployment and the question of decentralized or shifted production are closely related, one to the other. They stand out as subjects upon which thorough investigation by authorities having access to all the necessary information should be carried out within the immediate future. We are confident that once the facts are completely known to the American public, it will be possible to enact legislation necessary on these vast social problems.

We are convinced that intelligent action on the part of our government will be necessary to check and regulate the ruthless exploitation of men and communities by powerful corporations. Action along these lines, action to preserve the living standards of the unemployed, is, in our opinion, action to secure the future of this country.

Respectfully submitted.

THOMAS F. BURNS,
Vice-President, United Rubber Workers of America.

WORK PROJECTS ADMINISTRATION, NATIONAL RESEARCH PROJECT

David Weintraub, Director

REPORTS PUBLISHED AS OF APRIL 1940

GENERAL

- Unemployment and Increasing Productivity*, by David Weintraub assisted by Harold L. Posner, Report No. G-1, March 1937. Prepared for the National Resources Committee report, *Technological Trends and National Policy*.
The Research Program of the National Research Project, by Irving Kaplan, Report No. G-2, August 1937.
Summary of Findings to Date, March 1938, by David Weintraub and Irving Kaplan, Report No. G-3, March 1938.
Effects of Current and Prospective Technological Developments Upon Capital Formation, by David Weintraub, Report No. G-4, March 1939. Also published in the *American Economic Review*, Vol. XXIX, No. 1 (Mar. 1939), Supplement.
Industrial Change and Employment Opportunity—A Selected Bibliography, prepared under the supervision of Alexander Gourvitch with the assistance of Carolyn Blanks, Marion Hayes, Esther Skala, and Sophie Udin, Report No. G-5, July 1939.
Survey of Economic Theory on Technological Change and Employment, by Alexander Gourvitch, Report No. G-6, in press.
Selected References on Practices and Use of Labor on Farms, compiled by William A. Newman and Loring K. Macy, Report No. A-3, October 1937. Prepared under the supervision of John A. Hopkins.

STUDIES IN TYPES AND RATES OF TECHNOLOGICAL CHANGE

Manufacture

- Industrial Instruments and Changing Technology*, by George Perazich, Herbert Schimmel, and Benjamin Rosenberg, Report No. M-1, October 1938. Prepared under the supervision of George Perazich.

- Mechanization in the Brick Industry*, by Alfred J. Van Tassel and David W. Bluestone, Report No. M-2, June 1939. Prepared under the supervision of George Perazich.
- Mechanization in the Cement Industry*, by George Perazich, S. Theodore Wool, and Herbert Schimmel, Report No. M-3, December 1939. Prepared under the supervision of George Perazich.
- Industrial Research and Changing Technology*, by George Perazich and Philip M. Field, Report No. M-4, January 1940. Prepared under the supervision of George Perazich.
- Mechanization in the Lumber Industry*, by Alfred J. Van Tassel with the assistance of David W. Bluestone, Report No. M-5, March 1940. Prepared under the supervision of George Perazich.
- Mechanical Changes in the Cotton-Textile Industry, 1910 to 1936*, by Boris Stern, Report No. B-2, October 1937. Conducted in cooperation with the United States Department of Labor, Bureau of Labor Statistics, and prepared under the supervision of Boris Stern; reprinted from the *Monthly Labor Review*.
- Mechanical Changes in the Woolen and Worsted Industries, 1910 to 1936*, by Boris Stern, Report No. B-3, January 1938. Conducted in cooperation with the United States Department of Labor, Bureau of Labor Statistics, and prepared under the supervision of Boris Stern; reprinted from the *Monthly Labor Review*.
- Systems of Shop Management in the Cotton-Garment Industry*, by N. I. Stone, Report No. B-5, August 1938. Conducted in cooperation with the United States Department of Labor, Bureau of Labor Statistics, and prepared under the supervision of Boris Stern; reprinted from the *Monthly Labor Review*.

Mining

- Technology and the Mineral Industries*, by F. G. Tryon, T. T. Read, K. C. Heald, G. S. Rice, and Oliver Bowles, Report No. E-1, April 1937. Prepared for the National Resources Committee report, *Technological Trends and National Policy*; conducted in cooperation with the United States Department of the Interior, Bureau of Mines, and prepared under the supervision of O. E. Kiessling.
- Mechanization Trends in Metal and Nonmetal Mining as Indicated by Sales of Underground Loading Equipment*, by L. N. Plein, F. E. Berquist, and F. G. Tryon, Report No. E-3, June 1937. Conducted in cooperation with the United States Department of the Interior, Bureau of Mines, and prepared under the supervision of O. E. Kiessling.
- Fuel Efficiency in Cement Manufacture, 1909-1935*, by Nicholas Yaworski, Vivian Spencer, Geoffrey A. Saeger, and O. E. Kiessling, Report No. E-5, April 1938. Conducted in cooperation with the United States Department of the Interior, Bureau of Mines, and prepared under the supervision of O. E. Kiessling.
- Mineral Technology and Output per Man Studies: Grade of Ore*, by Andrew V. Corry and O. E. Kiessling, Report No. E-6, August 1938. Conducted in cooperation with the United States Department of the Interior, Bureau of Mines, and prepared under the supervision of O. E. Kiessling.
- Mineral Technology and Output per Man Studies: Rock Drilling*, by C. E. Nighman and O. E. Kiessling, Report No. E-11, February 1940. Conducted in cooperation with the United States Department of the Interior, Bureau of Mines, and prepared under the supervision of O. E. Kiessling.

Agriculture

- Changes in Farm Power and Equipment: Mechanical Cotton Picker*, by Roman L. Horne and Eugene G. McKibben, Report No. A-2, August 1937. Prepared under the supervision of John A. Hopkins.
- Changes in Farm Power and Equipment: Tractors, Trucks, and Automobiles*, by Eugene G. McKibben and R. Austin Griffin, Report No. A-9, December 1938. Prepared under the supervision of John A. Hopkins.
- Changes in Farm Power and Equipment: Field Implements*, by Eugene G. McKibben, John A. Hopkins, and R. Austin Griffin, Report No. A-11, August 1939. Prepared under the supervision of John A. Hopkins.

STUDIES IN PRODUCTION, PRODUCTIVITY, AND EMPLOYMENT

Manufacture

- Production, Employment, and Productivity in 59 Manufacturing Industries, 1919-36*, by Harry Magdoff, Irving H. Siegel, and Milton B. Davis, Report No. S-1, May 1939. Prepared under the supervision of Harry Magdoff.

- Productivity and Employment in Selected Industries: Beet Sugar*, by Raymond K. Adamson and Miriam E. West, Report No. N-1, October 1938. Conducted in cooperation with the National Bureau of Economic Research, and prepared under the supervision of Harry Jerome and William A. Neiswanger.
- Productivity and Employment in Selected Industries: Brick and Tile*, By Miriam E. West, Report No. N-2, February 1939. Conducted in cooperation with the National Bureau of Economic Research, and prepared under the supervision of Harry Jerome and William A. Neiswanger.
- Labor Productivity in the Leather Industry*, by John R. Arnold, Report No. B-1, October 1937. Conducted in cooperation with the United States Department of Labor, Bureau of Labor Statistics, and prepared under the supervision of Boris Stern; reprinted from the *Monthly Labor Review*.
- Effects of Mechanization in Cigar Manufacture*, by W. D. Evans, Report No. B-4, May 1938. Conducted in cooperation with the United States Department of Labor, Bureau of Labor Statistics, and prepared under the supervision of Boris Stern; reprinted from the *Monthly Labor Review*.
- Labor Productivity in the Boot and Shoe Industry*, by Boris Stern, Report No. B-6, February 1939. Conducted in cooperation with the United States Department of Labor, Bureau of Labor Statistics, and prepared under the supervision of Boris Stern; reprinted from the *Monthly Labor Review*.
- Mechanization and Productivity of Labor in the Cigar Manufacturing Industry*, prepared by W. D. Evans. Conducted in cooperation with the United States Department of Labor, Bureau of Labor Statistics, and prepared under the supervision of Boris Stern; published as Bulletin No. 660, September 1938, of the Bureau of Labor Statistics.
- Productivity of Labor in the Cotton-Garment Industry*, prepared by Nahum I. Stone assisted by Alfred Cahen and Saul Nelson. Conducted in cooperation with The United States Department of Labor, Bureau of Labor Statistics, and prepared under the supervision of Boris Stern; published as Bulletin No. 662, November 1938, of the Bureau of Labor Statistics.

Mining

- Small-Scale Placer Mines as a Source of Gold, Employment, and Livelihood in 1935*, by Charles White Merrill, Charles W. Henderson, and O. E. Kiessling, Report No. E-2, May 1937. Conducted in cooperation with the United States Department of the Interior, Bureau of Mines, and prepared under the supervision of O. E. Kiessling.
- Employment and Related Statistics of Mines and Quarries, 1935*, Part I, "Bituminous Coal," by F. G. Tryon, W. H. Young, M. E. Wilson, and F. E. Berquist and Part II, "Pennsylvania Anthracite," by F. G. Tryon, M. Otero, W. H. Young, and D. C. Ashmead, Report No. E-4, July 1937. Conducted in cooperation with the United States Department of the Interior, Bureau of Mines, and the United States Department of Commerce, Bureau of the Census, and prepared under the supervision of O. E. Kiessling.
- Technology, Employment, and Output per Man in Phosphate-Rock Mining, 1880-1937*, by A. Porter Haskell, Jr., and O. E. Kiessling, Report No. E-7, November 1938. Conducted in cooperation with the United States Department of the Interior, Bureau of Mines, and prepared under the supervision of O. E. Kiessling.
- Changes in Technology and Labor Requirements in the Crushed-Stone Industry*, by Harry S. Kantor and Geoffrey A. Saeger, Report No. E-8, February 1939. Conducted in cooperation with the United States Department of the Interior, Bureau of Mines, and prepared under the supervision of O. E. Kiessling.
- Mechanization, Employment, and Output per Man in Bituminous-Coal Mining*, by Willard E. Hotchkiss, F. G. Tryon, Charlotte K. Warner, L. N. Plein, Walter M. Dake, R. L. Anderson, J. J. Gallagher, and Margaret H. Schoenfeld, Report No. E-9, August 1939. Conducted in cooperation with the United States Department of the Interior, Bureau of Mines, and prepared under the supervision of O. E. Kiessling.
- Technology, Employment, and Output per Man in Petroleum and Natural-Gas Production*, by O. E. Kiessling, H. O. Rogers, G. R. Hopkins, N. Yaworski, R. L. Kiessling, J. Brian Eby, Lew Suverkrop, J. S. Ross, R. E. Heithecker, W. B. Berwald, Andrew W. Rowley, M. A. Scheilhardt, Richard Sneddon, Boyd Guthrie, Herbert Schimmel, and J. C. Albright, Report No. E-10, July 1939. Conducted in cooperation with the United States Department of the Interior, Bureau of Mines, and prepared under the supervision of O. E. Kiessling.

Technology, Employment, and Output per Man in Copper Mining, by Y. S. Leong, Emil Erdreich, J. C. Burrirt, O. E. Kiessling, C. E. Nighman, and George C. Heikes, Report No. E-12, February 1940. Conducted in cooperation with the United States Department of the Interior, Bureau of Mines, and prepared under the supervision of O. E. Kiessling.

Agriculture

Changes in Technology and Labor Requirements in Crop Production: Sugar Beets, by Loring K. Macy, Lloyd E. Arnold, Eugene G. McKibben, and Edmund J. Stone, Report No. A-1, August 1937. Prepared under the supervision of John A. Hopkins.

Changes in Technology and Labor Requirements in Crop Production: Potatoes, by Harry E. Knowlton, Robert B. Elwood, and Eugene G. McKibben, Report No. A-4, March 1938. Prepared under the supervision of John A. Hopkins.

Changes in Technology and Labor Requirements in Crop Production: Corn, by Loring K. Macy, Lloyd E. Arnold, and Eugene G. McKibben, Report No. A-5, June 1938. Prepared under the supervision of John A. Hopkins.

Changes in Technology and Labor Requirements in Crop Production: Cotton, by William C. Holley and Lloyd E. Arnold, Report No. A-7, September 1938. Prepared under the supervision of John A. Hopkins.

Changes in Technology and Labor Requirements in Crop Production: Wheat and Oats, by Robert B. Elwood, Lloyd E. Arnold, D. Clarence Schmutz, and Eugene G. McKibben, Report No. A-10, April 1939. Prepared under the supervision of John A. Hopkins.

Changes in Technology and Labor Requirements in Crop Production: Vegetables, by J. C. Schilleter, Robert B. Elwood, and Harry E. Knowlton, Report No. A-12, September 1939. Prepared under the supervision of John A. Hopkins.

Trends in Size and Production of the Aggregate Farm Enterprise, 1909-36, by Raymond G. Bressler, Jr., and John A. Hopkins, Report No. A-6, July 1938. Prepared under the supervision of John A. Hopkins.

Trends in Employment in Agriculture, 1909-36, by Eldon E. Shaw and John A. Hopkins, Report No. A-8, November 1938. Prepared under the supervision of John A. Hopkins.

STUDIES OF EFFECTS OF INDUSTRIAL CHANGE ON LABOR MARKETS

Recent Trends in Employment and Unemployment in Philadelphia, by Gladys L. Palmer, Report No. P-1, December 1937. Conducted in cooperation with the Industrial Research Department of the University of Pennsylvania and prepared under the supervision of Gladys L. Palmer.

The Labor Force of the Philadelphia Radio Industry in 1936, by Gladys L. Palmer and Ada M. Stoflet, Report No. P-2, April 1938. Conducted in cooperation with the Industrial Research Department of the University of Pennsylvania and prepared under the supervision of Gladys L. Palmer.

Employment and Unemployment in Philadelphia in 1936 and 1937, Part I, by Gladys L. Palmer and Part II by Margaret W. Bell and Gladys L. Palmer, Report No. P-3, August 1938 and October 1938. Conducted in cooperation with the Industrial Research Department of the University of Pennsylvania and prepared under the supervision of Gladys L. Palmer.

Ten Years of Work Experience of Philadelphia Weavers and Loom Fixers, by Gladys L. Palmer with the assistance of Kate Edelman, M. Eileen Leach, and Helen Klopfer, Report No. P-4, July 1938. Conducted in cooperation with the Industrial Research Department of the University of Pennsylvania and prepared under the supervision of Gladys L. Palmer.

Ten Years of Work Experience of Philadelphia Machinists, by Helen Herrmann, Report No. P-5, September 1938. Conducted in cooperation with the Industrial Research Department of the University of Pennsylvania and prepared under the supervision of Gladys L. Palmer.

Reemployment of Philadelphia Hosiery Workers After Shut-downs in 1933-34, by Gladys L. Palmer and Constance Williams with the assistance of Valda Noll, Report No. P-6, January 1939. Conducted in cooperation with the Industrial Research Department of the University of Pennsylvania and prepared under the supervision of Gladys L. Palmer.

The Search for Work in Philadelphia, 1932-36, by Gladys L. Palmer, Report No. P-7, May 1939. Conducted in cooperation with the Industrial Research Department of the University of Pennsylvania and prepared under the supervision of Gladys L. Palmer.

- The Long-Term Unemployed in Philadelphia in 1936*, by Gladys L. Palmer and Janet H. Lewis, Report No. P-8, August 1939. Conducted in cooperation with the Industrial Research Department of the University of Pennsylvania and prepared under the supervision of Gladys L. Palmer.
- Cigar Makers—After the Lay-Off*, by Daniel Creamer and Gladys V. Swackhamer, Report No. L-1, December 1937.
- Decasualization of Longshore Work in San Francisco*, by Marvel Keller, Report No. L-2, April 1939.
- Employment Experience of Paterson Broad-Silk Workers, 1926-36*, by James E. Wood, Report No. L-3, May 1939.
- Selective Factors in an Expanding Labor Market: Lancaster, Pa.*, by Edward J. Fitzgerald, Report No. L-4, June 1939.
- Labor and the Shut-down of the Amoskeag Textile Mills*, by Daniel Creamer and Charles W. Coulter, Report No. L-5, November 1939.
- Changes in Machinery and Job Requirements in Minnesota Manufacturing, 1931-36*, by Charles A. Koepke with the assistance of S. Theodore Woal, Report No. L-6, July 1939. Conducted in cooperation with the Employment Stabilization Research Institute of the University of Minnesota.
- Farm-City Migration and Industry's Labor Reserve*, by Francis M. Vreeland and Edward J. Fitzgerald, Report No. L-7, August 1939.
- Trade-Union Policy and Technological Change*, by Harry Ober, Report No. L-8, April 1940.
- Employment and Unemployment in A Depressed Labor Market: Brazil, Ind.*, by Miriam E. West, Edward J. Fitzgerald, and George L. Bird, Report No. L-9, in press.

REPORTS IN PREPARATION

- Labor Supply and Employment. Conducted under the supervision of Harry Magdoff.
- Production, Employment, and Productivity in Mineral Extraction. Conducted under the supervision of Harry Magdoff.
- Technology, Employment, and Output per Man in Iron Mining. Conducted in cooperation with the United States Department of the Interior, Bureau of Mines, under the supervision of O. E. Kiessling.
- Technology, Employment, and Output per Man in Lead and Zinc Mining. Conducted in cooperation with the United States Department of the Interior, Bureau of Mines, under the supervision of O. E. Kiessling.
- Technology, Employment, and Output per Man in Gypsum Mining. Conducted in cooperation with the United States Department of the Interior, Bureau of Mines, under the supervision of O. E. Kiessling.
- Technical and Resource Factors Influencing Output per Man in Anthracite Mining. Conducted in cooperation with the United States Department of the Interior, Bureau of Mines, under the supervision of O. E. Kiessling.
- Trends in Railroad Traffic, Revenues, and Investments. Conducted in cooperation with the Railroad Retirement Board under the supervision of A. G. Silverman.
- Technological Change and Investments in Railroad Property. Conducted in cooperation with the Railroad Retirement Board under the supervision of A. G. Silverman.
- Employment, Compensation, and Productivity of Railroad Labor. Conducted in cooperation with the Railroad Retirement Board under the supervision of A. G. Silverman.

1939	92.2	90.5	70.6	101.9	130.6

¹ Data for 1919-36 cover 59 industries that in 1929 accounted for 51 percent of the employment and 56 percent of the value of products of all manufacturing industries; the data are from Harry Magdoff, Irving H. Siegel, and Milton E. Davis, *Production, Employment, and Productivity in 59 Manufacturing Industries, 1919-36* (WPA National Research Project, Report No. 8-1, May 1939), Part One, p. 66. The figures for 1937-39 are estimated from incomplete data and are preliminary.

1939	80.0	60.3	57.2	132.7	139.9

¹ Data refer to Class I Steam Railroads. Production data for 1919-37 and employment data for 1921-37 are from M. L. Jacobsen, "Employment, Compensation, and Productivity of Railroad Labor" (WPA National Research Project in cooperation with Railroad Retirement Board, in preparation). In preparing the production index, data on revenue passenger miles and revenue ton miles as published by the Interstate Commerce Commission were combined by means of weights of 3 and 1, respectively. Production figures for 1938 and 1939 were computed from Interstate Commerce Commission data published in the *Survey of Current Business* (United States Bureau of Foreign and Domestic Commerce). The employment index is based on data of the Interstate Commerce Commission.

Crushed stone: ³	
Limestone.....	50
Basalt.....	75
Beet Sugar ⁴	54
Flour ⁵	65
Iron ore ⁶	30

¹ Small operations have an annual capacity of less than 15 million common-brick equivalents; large operations have an annual capacity of 30 million or more. Data are from Miriam E. West, *Productivity and Employment in Selected Industries: Brick and Tile* (WPA National Research Project in cooperation with National Bureau of Economic Research, Report No. N-2, Feb. 1939), p. 120.

² Small operations have an annual capacity of less than 1.0 million barrels; large operations have an annual capacity of 1.5 million or more. Data are from George Ferzich, S. Theodore Wool, and Herbert Schimmel, *Mechanization in the Cement Industry* (WPA National Research Project, Report No. M-3, Dec. 1939), p. 28.

³ Small operations produce less than 100,000 tons per year; large operations produce 100,000 or more. Data are from Harry S. Kantor and Geoffrey A. Saeger, *Changes in Technology and Labor Requirements in the Crushed-Stone Industry* (WPA National Research Project in cooperation with U. S. Department of the Interior, Bureau of Mines, Report No. E-8, Feb. 1939), p. 87.

⁴ Small operations have a daily capacity of less than 1,100 short tons; large operations have a daily capacity of 2,000 or more. Data are from Raymond E. Adamson and Miriam E. West, *Productivity and Employment in Selected Industries: Beet Sugar* (WPA National Research Project in cooperation with National Bureau of Economic Research, Report No. N-1, Oct. 1938), p. 100.

⁵ Small operations have an annual capacity of 200-349 thousand barrels; large operations have an annual capacity of 1,000 thousand or more. Data are from WPA National Research Project files, and are based on field survey data covering the years 1928-36.

⁶ Small operations have an annual capacity of less than 1 million tons of ore; large operations have an annual capacity of 1 million or more. Data are from N. Yaworski, O. E. Kiessing, and Others, *Technology, Employment, and Output per Man in Iron Mining* (WPA National Research Project in cooperation with U. S. Department of the Interior, Bureau of Mines, in preparation).

EXHIBIT No. 2767

PRODUCTIVITY AND EMPLOYMENT IN AGRICULTURE ¹

Over the years the volume of agricultural employment has been declining. From 1909 to 1929 the output per person working in agriculture increased 37 percent. This increased productivity made it possible for 7.5 percent fewer persons to produce an agricultural output which was 27 percent greater in 1929 than in 1909. The increased productivity reflects increased mechanization and other changes in agricultural techniques and such other factors as a shift of some marketing functions from agriculture to other industries. Although the average fertility of the soil has certainly not increased and although efforts toward a higher quality of agricultural products have tended to increase labor requirements, the improved techniques of production have nonetheless cut the total number of persons working in agriculture in spite of an increased output. For instance, it is estimated that since 1920 the combined harvester-thresher has displaced most of the 100,000 to 200,000 migratory harvest hands who used to find employment every summer in the wheat belts of the Great Plains; more recently many tenants and sharecroppers have lost their homes as well as their jobs when land owners in Texas and other southern States bought tractors and consolidated their holdings into larger, power-farmed units; and most recently the mechanization of corn harvesting appeared likely to wipe out in a few years the customary full employment of many thousands of corn huskers.

EXHIBIT No. 2768

EFFECTS OF TRACTOR AND MOTOR VEHICLES ON FARM LABOR REQUIREMENTS ¹

The widespread adoption of the tractor, supplanting draft animals as a source of power, has been by far the most important technological change in agriculture during the past 25 years. Not only has the tractor proved to be in many respects a more efficient power unit than the draft animal, but it also has made feasible the use of larger field implements and harvesting equipment which have reduced the labor time required to produce the country's crops. In many ways the automobile and the truck, too, have brought about outstanding changes in the farm economy. They have not only quickened and cheapened transportation on and off the farm but have also widened the area in which the farmer may advantageously buy supplies and sell his produce.

A major feature of the adoption of automotive equipment in agriculture has been the resultant decline in the number of horses and mules on farms. It is estimated that about 5.6 million mature draft animals have been displaced since 1909, with the tractor accounting for half and the truck and automobile for the other half. Without taking into account the tremendous increase in the amount of transportation which mechanical motive power has made feasible, the total saving in labor in the fields and in raising feed and caring for the animals which would have been required in the absence of tractors, trucks, and automobiles comes to about 1 billion man-hours per year. Against this must be set about 1¼ billion man-hours of work in nonfarm areas needed to produce the automotive equipment, to replace the worn-out units and parts, and to supply the necessary fuel and oil. This balance in favor of work created as against labor saved does not, however, tell the story of displacement on the farms, the migrations in search for new sources of income, and the unemployment which precedes the new job, if indeed it is found. In some parts of the country "tractored off" has therefore become synonymous with "displaced" and "technologically unemployed."

Continued adoption of tractors, trucks, and automobiles is anticipated. In 1937 there was 1 tractor to about 280 crop acres. Even if the number of farm tractors in use doubled during the next two decades, that number would provide only about half the farms of 50 acres or more with tractors. A particularly rapid rate of tractor adoption is to be looked for in the cotton-growing States, although, relative to some other areas, the number of tractors used in this region will probably be small for several years. Some increase in the use of automobiles and of trucks by farmers is also to be expected.

EXHIBIT No. 2769

EFFECTS OF CHANGES IN FIELD IMPLEMENTS ON FARM LABOR REQUIREMENTS ²

It is notable that few of the types of implements now widely used are entirely new since 1909, the beginning date for this study. New kinds of equipment have been developed for some purposes, especially for the harvesting of particular crops, but in most cases these new implements have been adopted by relatively few farmers. A much more important change in the last 25 or 30 years has been the adoption of larger or more efficient implements of types already existing. There has been a general increase in working widths, improvement in construction, and change in designs to permit work at higher operating speeds.

The National Research Project study of field implements shows that in almost all cases the labor required per crop-acre decreased progressively as the size of implements in use increased. This was true for each of the 26 implements studied and in all of the seven major farming areas in which the field survey was conducted. Where the motive power of tractors was substituted for that of horses, the productivity of labor using the same size of implement was usually much greater.

Although increased size of implement has been a general development, it has by no means affected all agricultural regions in equal degree. Thus in the eastern cotton areas farmers have been slow to shift to larger implements and larger power units. Tractors and larger equipment had been adopted on a few farms, but the implements most often found in 1936 were horse-drawn and of the same sizes as those most commonly reported in use more than a quarter of a century ago. In

¹ Based on letter of transmittal of Eugene G. McKibben and R. Austin Griffin, *Changes in Farm Power and Equipment: Tractors, Trucks, and Automobiles* (WPA National Research Project, Report No. A-9, Dec. 1938).

² Based on letter of transmittal of Eugene G. McKibben and Others, *Changes in Farm Power and Equipment: Field Implements* (WPA National Research Project, Report No. A-11, Aug. 1929).

the major wheat-producing areas, on the other hand, the implements most frequently in use 25 or 30 years ago had by 1936 been almost entirely replaced by larger-capacity equipment. Moreover, they were tractor-drawn and performed the operations of seedbed-preparation, planting, and harvesting in about three-tenths of the time required by the equipment that was typical before the World War.

Other areas fall between the extremes represented by the cotton and wheat areas. But even in the wheat region the equipment most commonly used in 1936 was considerably less effective than the most up-to-date types available and in use on some farms. This difference between implements used and improved implements available points to the existence of a broad physical basis for substantial further increases of labor productivity in agriculture.

EXHIBIT No. 2770

LABOR REQUIREMENTS IN COTTON PRODUCTION ¹

Of the country's five major crops, cotton requires much the greatest amount of labor, both in total and per acre. This crop also, more than most others, has resisted the tendency toward mechanization in agriculture, although recently there have been indications of an introduction of power farming in some of the major cotton-producing areas.

Between the periods 1907-11 and 1933-36 the labor requirements of cotton production declined by 16 percent per acre or, on a per-bale basis, by 20 percent. The greatest declines took place in the Western Cotton Area, that is, the area which also experienced the greatest increase in production during the period. The marked shift in the geographic distribution of cotton production to Oklahoma, Texas, and the far West has resulted in some economy in the utilization of labor. This shift is, however, partly offset by the increased proportions produced in the Delta Area, where labor requirements are above the average and where production has been more quickly adjusted to the changed requirements imposed by the boll weevil.

The decline in labor requirements per acre and per bale, in which all areas shared to some extent, reflects the increasing application of more efficient equipment. The development and introduction of large-scale and expensive equipment in cotton production has been seriously impeded by the small size of the farm unit and by the prevailing system of land tenure, particularly in the Old South. However, the accumulation of possibilities for economies through the use of modern equipment may overcome the resistance against extensive mechanization. These factors may in turn tend to change the tenancy and sharecropping system under which cotton is now raised in the Old South.

The tractor is now available for the preharvest operations of seedbed preparation, planting, and cultivation. Its use is feasible wherever the topography of the country presents level or gently rolling land, as in the Mississippi Delta, the Western Cotton Area of Oklahoma and northwest Texas, and the cotton lands of California, Arizona, and New Mexico. Under such conditions the use of the tractor is economical when cotton is grown on large farm units, such as exist in relatively greater numbers in the areas west of the Mississippi where the topography is most favorable. In all these areas tractors have been gradually replacing horsepower. Increasing sales of tractors and displacement of sharecroppers, with attendant increased demand for seasonal laborers, were reported in 1937. In the Mississippi Delta, for instance, sharecroppers and share tenants have already been displaced to some extent by wage labor, whereas in the western Areas a large proportion of the cotton has for some time been harvested by migratory labor.

A primary obstacle to the extended mechanization of preharvest operations is the peak labor requirements for harvesting operations. The development of the mechanical cotton picker raises prospects for overcoming this impediment. It is believed that machines now under development warrant expectations of their adoption during the next decade. They are especially adaptable to use on the relatively level lands favorable to the use of tractors, and they are likely to be used there first. A further shift in cotton production to such lands may then be expected, accompanied by an increase in the size of cotton farms. The successful development of a mechanical cotton chopper, such as was recently reported, would enhance the prospects for adoption of a successful cotton picker by reducing the secondary peak of labor requirements in cotton production.

¹ Based on preface of William C. Holley and Lloyd E. Arnold, *Changes in Technology and Labor Requirements in Crop Production: Cotton* (WPA National Research Project, Report No. A-7, Sept. 1938).

EXHIBIT No. 2771

LABOR REQUIREMENTS IN CORN PRODUCTION ¹

In this report it is estimated that, although production during the period 1932-36 was only slightly less than during the period 1909-13, the number of man-hours needed to produce the corn crop declined by more than 20 percent between the two periods. This reduction in the volume of work amounts to about 600 million man-hours, or the equivalent of 200,000 men working 3,000 hours a year. The decline in the amount of work needed cannot, however, be translated into reductions in actual employment because the volume of agricultural employment depends also on the other agricultural enterprises carried on and upon a great many factors which differ from area to area. Nonetheless, there is no doubt that the reduced volume of labor required to produce corn has contributed toward the general reduction in the volume of agricultural employment during the last two decades.

During the past 25 years the development and adoption of specialized machines in corn production have been extensive. Two-row cultivators have for the most part replaced one-row cultivators, except in the South, and in some areas much larger cultivators are in use. Lister planters which open the furrow and plant in one operation have come into use in western areas where semiarid climatic conditions reduce weed growth to negligible proportions. A variety of mechanical devices suited to the various methods of harvesting has been introduced. Potentially the most important of these is the mechanical corn picker. The adoption of this machine in the Corn Area has been increasing in recent years, and in 1937 some manufacturers reported more orders than they could fill.

The data indicate that changes in methods of harvesting corn, for instance, from husking by hand to mechanical picking in the Corn Area and from husking from the shock to ensiling in the Dairy Areas, have affected the volume of employment for transient seasonal laborers who work from 6 weeks to 2 months during the corn harvest.

The continued adoption of the mechanical corn picker in the Corn Area, which produces about 40 percent of the crop, will in all likelihood result in further displacement of seasonal laborers during the harvesting season. Furthermore, the adoption of tractors is still progressing in most corn-producing areas. Improved practices and wider adoption of hybrid seed corn promise higher yields per acre with little or no increase in the amount of labor needed. In the light of these findings and of the fact that corn production has not increased during the past quarter century, further declines in employment in the corn fields are predicted.

EXHIBIT No. 2772

LABOR REQUIREMENTS IN WHEAT PRODUCTION ²

For the country as a whole, the labor used per acre in wheat production declined during the period studied by more than 50 percent, or from 12.7 hours in the 1909-13 period to 6.1 hours in the 1934-36 period. The period of greatest reduction was the decade following the war, during which the average labor requirement decreased from 10.3 hours per acre to 6.7 hours. In this decade tractors and combines came into use in large numbers.

The greatest reductions have occurred in the more specialized wheat-producing areas. For instance, the amount of labor used per acre has declined in the Western Cotton Area by 68 percent, in the Range Area by 60 percent, in the Small Grain Area by 57 percent, and in the Northwestern Area by 53 percent. On the other hand, in the Eastern and Delta Cotton Areas labor requirements remained nearly the same throughout the period. In the Middle Eastern Area they were reduced only 7 percent and in the Eastern Dairy Area 24 percent.

According to our estimate the production of wheat in this country normally ³ required 367 million hours of farm labor annually in the 1934-36 period. This is over 240 million hours, or 40 percent, less than was used annually just prior to the

¹ Based on letter of transmittal of Loring K. Macy, Lloyd E. Arnold, and Eugene G. McKibben, *Changes in Technology and Labor Requirements in Crop Production: Corn* (WPA National Research Project, Report No. A-5, June 1938).

² Based on Robert B. Elwood, Lloyd E. Arnold, D. Clarence Schmutz, and Eugene G. McKibben, *Changes in Technology and Labor Requirements in Crop Production: Wheat and Oats* (WPA National Research Project, Report No. A-10, Apr. 1939), pp. 90-2, 94-96.

³ In order to eliminate the effect of the AAA program and the drought in recent years, the average acreage in the 1927-31 period was used in computing the normal labor needs in the 1934-36 period.

war. The reduction in the Small Grain Area alone amounts to 80 million man-hours, but in the Corn Area and the Western Dairy Area the labor used in wheat production has decreased 64 million and 41 million hours respectively.

One factor which has tended to reduce the labor needs of wheat production has been the trend toward expansion of acreage in areas of low per-acre labor requirements and contraction of acreage in areas where labor requirements are high. Thus in the Western Cotton Area the acreage in wheat increased by 232 percent from the 1909-13 to the 1927-31 period. A slight increase in total labor requirements has occurred there, whereas in the Dairy Areas, largely due to a reduction in acreage, there has been a substantial decrease in labor needs. The net effect of this shift in acreage has been to reduce the labor needed in wheat production in the country as a whole.

This reduction in the labor requirements of wheat production, besides reducing the need for regular farm labor prior to harvest, has virtually destroyed the demand for nonresident wheat-harvest laborers in those regions where the combine has come into general use. It has been estimated that in 1920 from 100,000 to 200,000 of these migratory laborers found employment in Texas, Oklahoma, Kansas, Nebraska, and the Dakotas. In the winter wheat belt, where the majority of these men were employed, combines now make it possible for the regular farm labor to complete the harvest with very little extra help.

EXHIBIT No. 2773

LABOR REQUIREMENTS IN OAT PRODUCTION ¹

The fact that oats are usually profitable only when grown in a diversified cropping system has resulted in the production of this crop remaining less mechanized than has that of wheat. Yet, with the exception of the labor used in the production of wheat and possibly barley, that used in the production of oats has declined more since 1909 than that of any other major crop.

Since the 1909-13 period the average amount of labor used in producing an acre of oats has declined from 12.5 to 7.9 hours, a reduction of 37 percent. In contrast with the production of wheat, where large reductions in labor requirements have occurred only in the specialized wheat-producing areas, reductions in the labor used in oat production have been comparatively uniform over a wide region. Reductions since 1909 in labor requirements per acre ranging from 34 to 44 percent have occurred in the Corn, Eastern Dairy, Western Dairy, Small Grain, Range, and Northwestern Areas. In California, an area of very small production, it is estimated that labor requirements per acre have decreased 72 percent since 1909. On the other hand, in the Eastern Cotton, Delta Cotton, and Middle Eastern Areas reductions in the labor used per acre range from 8 to 10 percent.

According to our estimates the normal annual labor needs of oat production in the 1934-36 period were roughly 316 million hours as compared with 458 million hours in the 1909-13 period. In the Corn and Eastern Dairy Areas the reduction amounted to over 30 million hours, and in the Western Dairy and Small Grain Areas the decline in labor needs has been nearly as great. Decreases ranging from 3 to 7 million hours have occurred in the Eastern Cotton, Delta Cotton, Range, Middle Eastern, and Northwestern Areas. The labor used in the Western Cotton Area increased more than 4 million hours during the period studied.

EXHIBIT No. 2774

LABOR REQUIREMENTS IN ALL SMALL-GRAIN PRODUCTION ²

The estimated reduction in the amount of labor used annually in producing and marketing small grains (wheat, oats, barley, and rye), totaling about 450 million man-hours, is the equivalent of 150,000 man-years of 3,000 hours of labor each. However, it is difficult to estimate the extent to which the decline in the labor requirements of these crops has actually affected employment in agriculture. The intricate and ever-changing relationships among the various farm enter-

¹ Based on Robert B. Elwood, Lloyd E. Arnold, D. Clarence Schmutz, and Eugene G. McKibben, *Changes in Technology and Labor Requirements in Crop Production: Wheat and Oats* (WPA National Research Project, Report No. A-10, Apr. 1939), pp. 96, 99.

² Based on Robert B. Elwood, Lloyd E. Arnold, D. Clarence Schmutz, and Eugene G. McKibben, *Changes in Technology and Labor Requirements in Crop Production: Wheat and Oats* (WPA National Research Project, Report No. A-10, Apr. 1939), pp. 102-3.

prises is such that all or part of the labor saved in one enterprise may merely be shifted to another. Or again, a reduction in the labor used in an enterprise may result in greater leisure for the farmer and his family without any actual reduction in employment.

In the regions where small grains are the most important crops, as in the Small Grain Area and in parts of the Western Cotton, Range, and Northwestern Areas, there has no doubt been a definite relationship between the hours of labor used in small-grain production and the number of persons employed in agriculture. Statistics of agricultural employment in the Small Grain Area appear to support this conclusion. Employment remained about constant from 1909 to 1930 while the indexes of crop acreage and livestock numbers were increasing about one-third and one-fourth respectively. From 1930 to 1936 employment in the Small Grain Area dropped 7 percent. Both hired labor and family labor have felt the impact of mechanization. Transient labor formerly used in harvesting has been displaced on many farms by the combine. The use of this machine and the tractor has increased the area which one family can operate so that vast areas of new land have been brought under cultivation with no increase in employment of farm operators and members of their families. In Montana, for example, the number of wheat farmers declined from 35,000 in 1915-17 to 14,000 in 1929, though wheat acreage rose about two-thirds. Much of this consolidation of farms was due to causes other than mechanization; yet the example indicates the trend throughout the Wheat Belt. Thus, the decreasing volume of work needed in the wheat fields of the middle western and eastern States due to the westward movement of wheat production has not been compensated for by increased employment in the newer areas.

It must be remembered, however, that from 70 to 80 percent of the small-grain acreage is located in diversified farming areas. On individual farms in these regions less employment does not necessarily follow a decline in small-grain acreage or in labor requirements of these crops. Nevertheless, these factors have undoubtedly been partial causes of declining agricultural employment in the Middle West and East.

EXHIBIT No. 2775

LABOR REQUIREMENTS IN POTATO PRODUCTION ¹

Potato production in recent years has not been much above the pre-war level. In the heavy potato-producing regions of the North and Northeast the labor required to produce a bushel of potatoes declined nearly 20 percent during the past 25 years. During that time the total labor required to produce the country's potato crop is estimated to have declined by about 45 million man-hours.

It is to be expected that further concentration of the country's potato crop lies ahead, as well as further mechanization of production, especially of the processes which consume most labor—picking up and grading. Machines for both of these processes are available, and an increase in their use is likely. It is also likely that the further development of disease- and pest-resistant varieties will make possible the elimination of part of the labor now needed to fight these blights.

EXHIBIT No. 2776

LABOR REQUIREMENTS IN VEGETABLE PRODUCTION ²

In contrast with other major crops, vegetable production and acreage have grown substantially and at a fairly steady rate during the past 30 years. Improvements in transportation and storage techniques and the opening up of new irrigated lands have been important factors in bringing about increased consumption in this field. Vegetables are produced commercially in all areas of the country. The increase in production has affected all areas in some degree but it has been especially marked in the Southwest and in California.

Growth of production, combined with a decline in average productivity that is unusual among agricultural products, has resulted since 1909 in doubling the

¹ Based on letter of transmittal of Harry E. Knowlton, Robert B. Elwood, and Eugene G. McKibben, *Changes in Technology and Labor Requirements in Crop Production: Potatoes* (WPA National Research Project, Report No. A-4, Mar. 1938).

² Based on letter of transmittal of J. C. Schillester, Robert B. Elwood, and Harry E. Knowlton, *Changes in Technology and Labor Requirements in Crop Production: Vegetables* (WPA National Research Project, Report No. A-12, Sept. 1939).

volume of labor required. The continuing growth of population, a persistence of the dietary trend toward greater use of vegetables (particularly green and leafy vegetables), and further improvements in quality and in transportation and storage methods are all likely to bring about further increases in vegetable consumption. The production of vegetables is thus one branch of agricultural enterprise which, in contrast with other branches, promises to afford an increase in employment opportunities.

Total man-hours of employment in this field, however, have recently amounted to only 2 or 3 percent of all direct labor used in agriculture. Furthermore, much of the employment afforded is highly seasonal in character, most of the jobs are casual, and a large part of the labor force (especially during the harvest periods) is composed of migratory men, women, and children.

EXHIBIT No. 2777

EMPLOYMENT AND RELIEF PROBLEMS AND MIGRATION OF THE LUMBER INDUSTRY¹

The economic dislocation which attended the decline of lumber production has been intensified in particular regions by the depletion of the timber resources. The traditional clear-cutting policy resulted in the migration of the industry to fresh sources of supply, leaving abandoned cut-over areas in its wake. In the period of agricultural expansion the population of these areas frequently made a successful transition to agriculture; studies of the Division of Research of the Work Projects Administration have shown that in recent years such areas have become, for want of alternative employment opportunity, centers of particularly aggravated relief problems.

Timber depletion has taken its toll of lumber and related forest industries, particularly in the Northeastern, Lake, and Central States. Although the southern lumber regions as a whole are not now similarly threatened, particular localities have been struck by the passing of the lumber industry. The United States Forest Service found that in 1934 there were over 18 thousand workers employed in southern logging and sawmilling operations of large mills whose owners expected to exhaust their local timber supplies by 1944. The expected increase in the number of small and medium-size mills is not likely to enhance the employment security of workers attached to such mills because of the prospective depletion of the timber supply within the working area of the mills. Although in the Pacific Coast States fewer localities are subject to the same imminent dangers, the potential economic dislocation due to timber depletion is much greater because of the strategic position occupied by the forest industries in the economy of the Northwest.

EXHIBIT No. 2778

EFFECTS OF MECHANIZATION OF BITUMINOUS-COAL MINING ON LABOR REQUIREMENTS²

Technical advances underground and on the surface reduced the number of men required to mine a given volume of coal, though doubtless aiding coal to meet the competition of other sources of power. At underground mines the average output per mine worker per hour increased by 24 percent between 1920 and 1935. The continued spread of the mechanical devices that were available before the war, such as the undercutting machine; the electrification of underground transportation; and improvements in mine lay-out and management methods contributed toward the rising output per worker. Shortly after the war a new machine, the mechanical coal loader, was introduced.

In a mine in which coal is loaded by hand, from one-half to two-thirds of the entire working force consists of miners who, in addition to undercutting the seam and preparing shot holes for blasting down coal, shovel the coal into mine cars. Most of their time is spent in loading coal and the mechanization of this process can obviously have an important effect on the amount of labor required by the mines.

¹ Based on letter of transmittal of Alfred J. Van Tassel with the assistance of David W. Bluestone, *Mechanization in the Lumber Industry* (WPA National Research Project, Report No. M-5, Mar. 1940).

² Based on letter of transmittal of Willard E. Hotchkiss, F. G. Tryon, and Others, *Mechanization, Employment, and Output per Man in Bituminous-Coal Mining* (WPA National Research Project in cooperation with Department of the Interior, Bureau of Mines, Report No. E-9, Aug. 1939).

Machine loading was adopted slowly in the early years of its introduction. Only 0.3 percent of all underground bituminous-coal tonnage was loaded by machine in 1923. By 1929 the percentage was 7.3 and in 1935 it was 13.5. Between 1935 and 1937 the machine-loaded tonnage increased from 47 to 83 million tons, or to 20.3 percent of all underground production, and it is estimated that in 1938 one-quarter of the output was loaded mechanically.

The installation of mechanical loaders has not taken place at an even rate in all producing areas. During the twenties and the years between 1930 and 1935 it had its principal acceptance in the great Illinois-Indiana producing district and in some of the less important producing States of the far West. In West Virginia, the country's leading coal producer, 21 percent of the output was mechanically loaded in 1938 as compared with 2 percent in 1935. While it was being adopted to an increased extent in other areas the coal loader also continued to be more extensively used in Illinois and Indiana.

It is estimated that within another decade as much as half of the total underground output may be mechanically loaded. How this will affect employment in the industry depends upon a multitude of factors. Between 1929 and 1935 output per man-hour in underground mines increased by 5 percent and production declined by 32 percent, but the average number of men employed declined by only 9 percent. The men have worked fewer hours per day and fewer days per year.

Some mines and mining communities which by virtue of natural conditions or other factors have been unable to adopt mechanical loaders are being placed in unfavorable competitive positions and are finding their employment opportunities restricted. Some of the older miners, accustomed to the tempo of hand-loading mines, are finding themselves displaced and unable to gain a foothold in the mechanized mines. To many of these communities and for many of these older miners emergency relief measures of one type or another are the only alternative to destitution as long, at least, as mass unemployment remains a problem in the United States.

¹ Based on data from interviews with a sample of 357 workers in Philadelphia, Pa., whose usual occupation in May 1936 was weaving or loom fixing in one of the following industries: woolen and worsted, carpet and rug, and upholstery fabrics. All were able to work and were either employed or looking for work on May 1, 1936. Data are from Gladys L. Palmer and Others, *Ten Years of Work Experience of Philadelphia Weavers and Loom Fixers* (WPS National Research Project in cooperation with Industrial Research Department, University of Pennsylvania, Report No. P-4, July 1938), table 28, p. 80.

² Base too small for calculation.

EXHIBIT No. 2782

*Age distribution of cigar-machine operators and of hand cigar makers whom they replaced*¹

Ages on July 1, 1931	Machine operators		Hand cigar makers	
	Number	Percent	Number	Percent
Total.....	184	100.0	321	100.0
16-19 years.....	34	18.5	0	0
20-24 years.....	49	26.6	7	2.2
25-34 years.....	59	32.1	53	16.5
35-44 years.....	31	16.8	77	24.0
45-54 years.....	9	4.9	100	31.2
55-64 years.....	2	1.1	63	19.6
65 and over.....	0	0	21	6.5
Median (age in years).....	26.2		47.0	

¹ All of the machine operators were women; all of the hand makers were men. The company, located in Manchester, N. H., changed over from hand to machine manufacture of cigars in 1931. During that year the men were laid off and the women were hired. Data are from Daniel Creamer and Gladys V. Swackhamer, *Cigar Makers—After the Lay-off* (WPA National Research Project, Report No. L-1, Dec. 1937), table 8.

EXHIBIT No. 2783

*Employment status of hand cigar makers during five years following displacement in 1931*¹

Employment status	Number of months	Percent of total
Total elapsed time between lay-off and date of interview.....	8,287	100.0
Unemployed not seeking work.....	959	11.6
Unemployed seeking work.....	4,300	52.6
Employed in cigar industry for others.....	842	10.2
Employed in cigar industry for self ²	729	8.8
Employed in other than cigar industry.....	1,397	16.8

¹ Based on data for 129 men interviewed in February 1937. All were laid off during 1931 when the Manchester, N. H., company which had employed them introduced cigar-making machines. Data are from Daniel Creamer and Gladys V. Swackhamer, *Cigar Makers—After the Lay-off* (WPA National Research Project, Report No. L-1, Dec. 1937), table 22.

² This constituted chiefly a form of disguised unemployment (*Ibid.*, pp. 51-7).

SUPPLEMENTAL DATA

The following letter appears at this point in connection with the testimony of William S. Elliott, supra, p. 17079.

INTERNATIONAL HARVESTER COMPANY, INCORPORATED
180 North Michigan Avenue, Chicago, U. S. A.

JULY 9, 1490.

Dr. H. DEWEY ANDERSON,
Temporary National Economic Committee,
Apex Building, Washington, D. C.

DEAR SIR: On April 24, 1940, I made the following request of the Temporary National Economic Committee:

"I would like to ask, if I may, that we might have permission to put into the record some statements of our own as to our estimates of the relative cost of horse-farming and power-farming. We find the industry in a curious position—Dr. Johnson of the Department of Agriculture put figures in here yesterday to show that the farmer made no more money out of tractor farming than he did out of horse-farming, and today Dr. Taylor shows that it is so much more economical that it is sweeping the country and will go further."

The Department of Agriculture statements above referred to appear in the TNEC record as exhibits No. 2663 and No. 2664. From these statements and the working papers which Dr. Sherman E. Johnson has kindly made available to us, it appears that the comparisons of income and expense of farms using animal power and tractor power are based on only one wheat farm and one corn farm. The excess of income over expense, the dollar difference and the percentage difference resulting from the use of horse or tractor power as shown in said exhibits are summarized in the following tabulation:

	Excess of Income Over Expense by the Use of		Dollar Difference	Percentage Difference
	Horses	Tractors		
320 Acre Wheat Farm.....	\$844	\$633	-\$11	-1.7%
200 Acre Corn Farm.....	2847	2922	+75	+2.6

Individual cases such as the two selected above can be found, where the advantage of tractor power over animal power is very slight or entirely absent, but we believe such cases are the exception, rather than the rule.

It is our understanding that the above tables had to be selected by the USDA for presentation to the TNEC on very short notice. Had there been more time for preparation, data based on a larger number of wheat and corn farms could have been selected from the numerous publications of State Colleges which cooperate with USDA. This would have enabled the USDA to base its conclusions on a representative sample of wheat and corn farms, rather on such a thin sample as one wheat and one corn farm.

In the case of the study presented by the USDA to the TNEC on cotton production which was based on a larger number of farms, the excess of income over expense on tractor-operated farms under normal conditions was substantially larger than on mule-operated farms. Basing a judgment on our studies of all published data available, we believe that similar difference would be found on any representative number of wheat and corn farms.

In further support of our claim that it is dangerous to base a judgment on the comparative cost of operating a single farm with tractors and horses, we submit the following criticisms of the wheat cost data submitted to the USDA by its field forces and resubmitted by USDA to TNEC:

Cost of "Machinery (repairs, fuel, oil)"—Under this cost classification, \$96 appears for the horse-powered farm and \$543 for the tractor-powered farm. The breakdown of this cost for the tractor farm is as follows:

Tractor fuel—1800 gal. @ 12¢	-----	\$216. 00
Tractor oil—75 gal. @ 60¢	-----	45. 00
Total for 600 hours	-----	\$261. 00
Tractor and combine repairs	-----	61. 00
Truck operation (fuel, oil & repairs)—5000 mi. @ 2½¢	-----	125. 00
Repairs on tillage and other equipment	-----	96. 00
Total	-----	\$543. 00

CRITICISM

(a) The tractor farm costs are loaded with \$125.00 of expense for operating a motor truck. The changeover to tractor power would not necessarily require the acquisition of a motor truck and does not ordinarily result in the purchase of a motor truck, particularly in cases such as on this farm, where it is apparent that a number of horses were retained on the farm after it became a tractor farm. Iowa State College in its Research Bulletin No. 258 showed that out of 1711 farms studied, only 24% had motor trucks. These were found on 10% of the horse farms and 29% of the tractor farms. Furthermore, 72% of the farms had tractors but there were only 11 on which no horses were kept.

The University of Illinois study of costs on Illinois farms in 1938 showed that only three out of 27, or 11.1% of the farms had motor trucks.

(b) The repairs for tillage and other equipment are given as \$96, precisely the same as the entire repairs, fuel, and oil cost on the horse-powered farm. There are several machines, such as the grain binder, bundle racks, wagons and also harness that are used on horse-powered farms but not on tractor farms. Operating cost for this extra machinery was not charged on horse powered farms.

(c) In the USDA calculation, it was assumed that tractors were used 60 days for an average of ten hours per day. On that basis, the fuel and oil cost of \$261 for the tractor would average 43.5 cents per hour. This cost is excessive when compared with the results of other studies. The following table shows a comparison of tractor fuel and oil costs.

Study or Source	Type of Tractor	Number of Tractors on Which Average Is Based	Cost per hour Fuel and Oil
USDA Statement to TNEC	?	?	43. 5¢
University of Minnesota: Report No. 108:			
1935	Two plow	4	23. 6
1936	"	9	30. 9
1937	"	10	26. 7
1938	"	13	25. 8
4 year average:	"		26. 7
1935	Three plow	9	19. 2
1936	"	9	30. 7
1937	"	11	31. 3
1938	"	7	34. 9
4-year average	"		29. 0
Iowa State College: Research Bulletin 1936-37 No. 258	General Purpose		
"	Two Plow:		
"	Steel Wheel	73	27. 6
"	Rubber tire	61	22. 7
"	Three Plow:		
"	Stl. & Rubr.	20	32. 8
"	Standard Type:		
"	Two Plow	66	31. 3
"	Three Plow	39	36. 9
University of Illinois: 1938 Farm Business Analysis:			
1936	Two Plow	18	24. 5¢
1937	"	23	20. 3
1938	"	22	20. 8
1930	Three Plow	8	31. 7
1937	"	9	30. 0
1938	"	9	28. 3

This table shows that in none of these representative studies did the cost per hour for fuel and oil, even for three-plow tractors, approach the calculated amount shown in the United States Department of Agriculture's table.

(d) The item of \$61 for tractor and combine repairs is also high. How much of this applies to combine and how much to tractor is not stated, but considerably more than half would naturally apply to tractors. This can be compared with the actual average repairs cost as found by studies at Iowa State College and the University of Illinois. The Iowa State College studies found that in 1936-37 the average repairs cost for 73 steel wheel two-plow general purpose tractors was \$13.16; for 61 rubber tired, two-plow general purpose tractors it was \$19.38; for 20 three-plow general purpose tractors it was \$19.15; for 66 standard type, two plow steel wheel tractors it was \$15.00 and for 39 three-plow standard type steel wheel tractors it was \$30.54.

The University of Illinois study showed that in 1936 the average cost of repairs for 18 two-plow tractors was \$22.94; in 1937 for 23 two-plow tractors it was \$13.51 and in 1938 for 22 two-plow tractors it was \$15.65. The same study shows the following average per-tractor repairs for three-plow tractors in 1936-8 tractors average repair cost \$20.70; in 1937 9 tractors average repair cost of \$11.59 and in 1938-9 tractors average repair cost of \$14.18.

"Purchased Feed".—This figure is the same for both types of farms because it is said most of the horse feed was produced on the farm and the purchased feed is used primarily for other types of livestock than horses. The horse feed necessary has been taken care of by adjustment of the feed crop acreages.

CRITICISM

If a comparison of costs between horse and tractor use is desired, the cost of horse feed should be included with the other costs of horse maintenance, regardless of whether horse feed was purchased or produced on the farm. Another objection to the method of acreage adjustment used by the Department of Agriculture is that a specific acreage cannot be accurately allocated to the production of horse feed. The acreage used might produce too much or not enough feed, depending upon crop conditions in which case, either the sale or purchase of feed would be in order. Clear and accurate cost accounting demands that the horse feed used be included under its proper caption rather than allowed for through an acreage adjustment.

Depreciation.—Depreciation of horses is not included in the costs of the horse-power farm. This is an omission which would raise the cost of the horse-power farm considerably.

The same amount of pasture and woodland was assumed for each type of farm. No charge or acreage adjustment is made for the extra pasturage required by horses on the horse-power farm. This cost, like the depreciation on horses, is ignored by the comparison.

General.—The corn cost submitted by the United States Department of Agriculture are also based on the operation of a single farm and are not, in our judgment, representative costs. We shall not, however, write detailed criticisms as in the case of the wheat farm.

In conclusion, we wish to submit that our studies and observations indicate that in general it is cheaper to farm with tractors than with animal power and the fact that more than a million United States farmers have purchased tractors indicates that they are convinced that tractor power is cheaper power.

Yours very truly,

(Signed) Wm S ELLIOTT,
Wm. S. Elliott,
Vice-President.

WSE/RC
