dX = - \frac{4}{3} \rho f \frac{c^1}{1 + 2\varepsilon} dc, \quad dZ = - \frac{4}{3} \rho h \frac{c^1}{1 + 2\varepsilon} de.
\]

To apply this to our heterogeneous spheroid, if we put \( c_1 \) for the semiaxis of that surface of equal density on which is situated the attracted point \( P \), and \( c_0 \) for the semiaxis of the outer surface, the attraction of that portion of the body which is exterior to \( P \), namely, of all the shells which inclose \( P \), has for components

\[
x_0 = - \frac{8}{15} \pi f \frac{c^0}{1 + 2\varepsilon} dc, \quad z_0 = \frac{16}{15} \rho \frac{h}{1 + 2\varepsilon} de,
\]

both \( e \) and \( \rho \) being functions of \( c \). Again the attraction of a homogeneous spheroid of density \( \rho \) on an external point \( f, h \) has the components

\[
x = \frac{4}{3} \rho \frac{c^0}{1 + 2\varepsilon} \left( \chi (1 + 2\varepsilon) - \lambda c^0 \right),
\]

\[
z = \frac{4}{3} \rho \frac{c^0}{1 + 2\varepsilon} \left( \chi (1 + 2\varepsilon) - \lambda c^0 \right),
\]

where \( \lambda = \frac{3}{5} \frac{4h^2 - R^2}{r^2}, \quad \chi = \frac{3}{5} \frac{2h^2 - 3R^2}{r^2}, \) and \( r^2 = f^2 + h^2 \).

Now \( e \) being considered a function of \( c \), we can at once express the attraction of a shell (density \( \rho \)) contained between the surface defined by \( c + dc \), \( c - de \) and that defined by \( c, e \) upon an external point, the differentials \( c, de \) and \( c, e \) with respect to \( c, e \), viz. \( dX, dZ \), must then be integrated with \( \rho \) under the integral sign as being a function of \( c \). The integration will extend from \( c = 0 \) to \( c = s \). Thus the components of the attraction of the heterogeneous spheroid

\[
\text{VII.} - 76
\]
upons a particle within its mass, whose coordinates are \( f, 0, h \), are

\[
X = -\frac{4}{5} \pi \rho f \left\{ \frac{1}{5} \int_0^1 \rho d \sigma \left( 1 + 2a^2 + \frac{2}{5} \sigma (\sigma^2 - 1) \right) \right\}
\]

\[
Z = \frac{4}{5} \pi \rho h \left\{ \frac{1}{5} \int_0^1 \rho d \sigma \left( 1 + 2a^2 + \frac{2}{5} \sigma (\sigma^2 - 1) \right) \right\}
\]

We take into account the rotation of the earth by subtracting the centrifugal force \( f^2 = F \) from \( X \). Now, the surface of constant density upon which the point \( f, 0, h \) is situated gives \( (1 - 2a^2)f + kh = 0 \); and the condition of equilibrium is that \( (X - F)f + Z = 0 \). Therefore,

\[
(X - F)h = Zf(1 - 2a^2)
\]

which, neglecting small quantities of the order \( e^2 \) and putting \( \rho d \sigma = 4\pi e^2 \), gives

\[
\frac{2\pi}{3} \int_0^1 \rho d \sigma \left( 1 + 2a^2 - \frac{6}{5} \sigma (\sigma^2 - 1) \right) = \frac{2\pi}{3} \int_0^1 \rho d \sigma \left( 1 - 2a^2 \right).
\]

Here we must put now \( c \) for \( c_1 \), \( f \) for \( f_1 \), and \( 1 + 2e \) under the integral sign may be replaced by unity. Two integrations lead us to the following very important differential equation:

\[
\frac{2\pi}{3} \int_0^1 \rho d \sigma (1 + 2a^2) = \frac{2\pi}{3} \int_0^1 \rho d \sigma (1 - 2a^2),
\]

and putting \( c = c_0 \) in the equation expressing the condition of equilibrium, we find

\[
M(2r - m) = \frac{2\pi}{3} \int_0^1 \rho d (\rho^2 d\sigma).
\]

Making these substitutions in the expressions for the forces at the surface, and putting \( r = 1 + \epsilon - e \cos \theta \), we get

\[
G \cos \phi = \frac{M}{ac} \left\{ 1 + e | \frac{3}{2} - \frac{5}{2} m - \frac{5}{2} \left( m - 2a^2 \right) \left( \frac{5}{3} - m \right) \right\} \frac{2\pi}{3} \int_0^1 \rho d (\rho^2 d\sigma),
\]

\[
G \sin \phi = \frac{M}{ac} \left\{ 1 + e | \frac{3}{2} + \frac{5}{2} m + \frac{5}{2} \left( m - 2a^2 \right) \left( \frac{5}{3} - m \right) \right\} \frac{2\pi}{3} \int_0^1 \rho d (\rho^2 d\sigma).
\]

Here \( G \) is gravity in the latitude \( \phi \), and \( a \) the radius of the equator. Since \( \sin \phi = \frac{2\pi}{3} \int_0^1 \rho d (\rho^2 d\sigma) \), we get

\[
G = \frac{M}{ac} \left\{ \frac{1}{2} \int_0^1 \rho d (\rho^2 d\sigma) \right\}.
\]

which expression contains the theorems we have referred to as discovered by Clairaut.

The theory of the figure of the earth as a rotating ellipsoid has proved an attractive subject to many of the greatest mathematicians, Laplace especially, who has devoted a large portion of his Mécanique Céleste to it. In English the principal existing works on the subject are Sir George Airy's Mathematical Tracts, where the subject is treated in the lucid style so characteristic of its author, but without the use of Laplace's coefficients, Archdeacon Pratt's Attractions and Figure of the Earth, and O'Brian's Mathematical Tracts, in the last two Laplace's coefficients are used. In the Cambridge Tracts, vol. vi., is a valuable essay by Professor Stokes, in which he proves, without making any assumption whatever as to the ellipticity of internal strata, or as to the past or the present fluidity of the earth that if the external form of the sea—imagined to percolate the land by canals—be a spheroid with small ellipticity, then the law of gravity will be that found above \( \epsilon \). An important theorem by Jacoby must not be overlooked. He proved that for a homogeneous fluid in rotation a spheroid is not the only form of equilibrium; an ellipsoid rotating round its least axis may with certain proportions of the axes and a certain time of revolution be a form of equilibrium.\(^2\)

Local Attraction.

In speaking of the figure of the earth, we mean the surface of the sea imagined to percolate the continents by canals. That this surface should turn out, after precise measurements, to be exactly an ellipsoid of revolution is a priori improbable. Although it may be highly probable that originally the earth was a fluid mass, yet in the cooling whereby the present crust has resulted, the actual solid surface has been left in form the most irregular. It is clear that these irregularities of the visible surface must be accompanied by irregularities in the mathematical figure of the earth, and great care must be taken that the error in the major semiaxes may not be precisely any surface of revolution. Nevertheless, there must exist some spheroid which agrees very closely with the mathematical figure of the earth.

\(^1\) See also a paper by Professor Stokes, in the Cambridge and Dublin Mathematical Journal, vol. iv. 1849.

\(^2\) See a paper in the Proceedings of the Royal Society, No. 123 1870, by L. Todhunter, M.A., F.R.S.
each in mean latitudes, and near each other, say about five degrees of latitude apart, the probable error of the resulting value of the ellipticity will be approximately \( \varepsilon \), being expressed in seconds, so that if \( \infty \) be so great as 2\(^\circ\) the probable error of the resulting ellipticity will be greater than the ellipticity itself. It is not only interesting, but necessary at times, to calculate the attraction of a mountain, and the consequent disturbance of the astronomical zenthr, at any point within its influence. The deflection of the plumb-line, caused by a local attraction whose amount is \( \Delta_s \), is measured by the ratio of \( \Delta s \) to the force of gravity at the station. Expressed in seconds, the deflection \( \Delta \) is

\[
\Delta = 12'' \cdot \frac{472}{\rho}
\]

where \( \rho \) is the mean density of the earth, \( \delta \) that of the attracting mass,—the linear unit in expressing \( \Delta \) being a mile. Suppose, for instance, a table-land whose form is a rectangle of twelve miles by eight miles, having a height of 500 feet and density half that of the earth, let the observer be two miles distant from the middle point of the longer side. The deflection then is 1'\(^\circ\) 472, but at one mile it increases to 2'\(^\circ\) 20. At sixteen astronomical stations in the English Survey the disturbance of latitude due to the form of the ground has been computed, and the following will give an idea of the results. At six stations the deflection is under 2', at six others it is between 2' and 4', and at four stations it exceeds 4'.

There is one very exceptional station on the north coast of England, near the village of Portsea, at which the deflection amounts to 10', so that if that village were placed on a map in a position to correspond with its astronomical latitude, it would be 1000 feet out of position. There is the sea to the north and an undulating country to the south, which, however, to a spectator at the station does not suggest any great disturbance of gravity. A somewhat rough estimate of the local attraction from external causes gives a maximum limit of 5\(^\circ\), therefore we have 5\(^\circ\) unaccounted for, or rather which must arise from unequal density in the underlying strata in the surrounding country. In order to throw light on this remarkable phenomenon, the latitudes of a number of stations between Narm on the west, Fraserburgh on the east, and the Grampians on the south, were observed, and the local deflection determined. It is somewhat angular that the deflections diminish in all directions, not very regularly certainly, and most slowly in a south-west direction, finally disappearing, and leaving the maximum at the original station at Portsea.

The method employed by Dr Heath for computing the attraction of masses of ground is so simple and effectual that it can hardly be improved on. Let a horizontal plane pass through the given station; let \( r, \theta \) be the polar coordinates of any point in this plane, and \( r_1, \theta_1 \) the coordinates of a particle of the attracting mass, and let it be required to find the attraction of a portion of the mass contained between the horizontal planes \( z = 0, z = h \), the cylindrical surfaces \( r = r_1, r = r_2 \), and the vertical planes \( \theta = \theta_1, \theta = \theta_2 \). The component of the attraction at the station or origin along the line \( \theta = 0 \) is

\[
\frac{\mu}{2 \pi} \left( \frac{r^2}{r^2 + h^2} \right) \left( \frac{r^2}{r^2 + h^2} \right) \cos \theta_1 \cos \theta_2 \log \frac{r + \sqrt{r^2 + h^2}}{r_2 + \sqrt{r_2^2 + h^2}}
\]

By taking \( r_2 \) sufficiently small, and supposing \( h \) also small, as it usually is, compared with \( r_1 + r_2 \), the attraction is

\[
-\frac{3}{2} k \frac{\mu}{2 \pi} \left( \frac{r^2}{r^2 + h^2} \right) \cos \theta_1 \cos \theta_2 \log \frac{r + \sqrt{r^2 + h^2}}{r_2 + \sqrt{r_2^2 + h^2}}
\]

where \( r = \frac{1}{2} (r_1 + r_2) \). This form suggests the following procedure. Draw on the contoured map a series of equidistant circles, concenter with the station, intersected by radial lines so disposed that the areas of their annuli are in arithmetical progression. Then, having estimated from the map the mean heights of the various compartments, the calculation is obvious.

In mountainous countries, as near the Alps and in the Caucasus, deflections have been observed to the amount of as much as 29\(^\circ\). On the other hand, deflections have been observed in flat countries, such as that noted by Professor Schweizer, who has shown that, at certain stations in the vicinity of Moscow, within a distance of 15 miles the plumb-line varies 16\(^\circ\) in such a manner as to indicate a vast deficiency of matter in the underlying strata. But these are exceptional cases. Since the attraction of a mountain mass is expressed as a numerical multiple of \( \delta/\rho \), the ratio of the density of the mountain to that of the earth, if we have any independent means of ascertaining the amount of the deflection, we have at once the ratio \( \rho/\delta \), and thus we obtain the mean density of the earth, as, for instance, at Schelchthon, and more recently at Arthur's Seat. A compact mass of great density at a small distance under the surface of the earth will produce an elevation of the mathematical surface which is expressed by the formula

\[
y = a \left[ \frac{1}{(1 + \kappa^2 - 2 \kappa \cos \theta)^{1/2}} \right] - 1
\]

where \( a \) is the radius of the (spherical) earth, \( a(1-\kappa) \) the distance of the disturbing mass below the surface, \( \mu \) the ratio of the disturbing mass to the mass of the earth, and \( a(1-\kappa) \) the distance of any point on the surface from that point, say \( Q \), which is vertically over the disturbing mass. The maximum value of \( y \) is at \( Q \), where it is

\[
y = -a \frac{k}{1 - \kappa} - \frac{a^2}{2}
\]

The deflection at the distance \( a(1-\kappa) \) is

\[
\Delta = -a \frac{k}{1 - \kappa} \frac{a^2}{2}
\]

or since \( \theta \) is small, putting \( h = \kappa = 1 \),

\[
\Delta = -a \frac{a^2}{2}
\]

The maximum deflection takes place at a point whose distance from \( Q \) is to the depth of the mass as \( 1 : \sqrt{2} \), and its amount is

\[
\frac{\mu}{2 \pi} \frac{a^2}{2}
\]

If, for instance, the disturbing mass were a sphere a mile in diameter, the excess of its density above that of the surrounding country being equal to half the density of the earth, and the depth of its centre half a mile, the greatest deflection would be 5\(^\circ\), and the greatest value of \( y \) only two inches. Thus a large disturbance of gravity may arise from an irregularity in the mathematical surface whose actual magnitude, as regards height at least, is extremely small.

The effect of the disturbing mass \( \mu \) on the vibrations of a pendulum would be a maximum at \( Q \), if \( v \) be the number of seconds of time gained per day by the pendulum at \( Q \), and \( \sigma \) the number of seconds of angle in the maximum deflection, then it may be shown that

\[
y = \frac{v^2}{2}
\]

1 In the Philosophical Transactions for 1855 and 1859 will be found Airchensoff Pratt's calculations of the attractions of the Himalayas and the mountain region beyond them, and the consequent deflection of the plumb-line at various stations in India; the subject, which presents many anomalies and difficulties, is very fully taken up in his treatise on the figure of the earth. His computed deflections are vastly greater than anything brought to light by observation.
so that the number of seconds of time by which the maximum the pendulum is accelerated is about half the number of seconds of angle in the maximum deflection.

Principles of Calculation.

Let \( a, a' \) be the mutual azimuths of two points \( P, Q \) on a spheroid, \( k \) the chord line joining them, \( \mu, \mu' \) the angles made by the chord with the normals at \( P \) and \( Q, \phi, \phi' \) their latitudes and difference of longitude, and \( \frac{z'}{R} + \frac{z}{R} = 1 = 0 \) the equation of the surface; then if the plane \( z \) passes through \( P \) the co-ordinates of \( P \) and \( Q \) will be

\[
\begin{align*}
\alpha &= \frac{a}{\Delta} \cos \phi, \\
\alpha' &= \frac{a}{\Delta} \cos \phi' \cos \omega, \\
y &= 0, \\
y' &= \frac{a'}{\Delta} \cos \phi' \sin \omega, \\
z &= \frac{a}{(1 - e^2) \sin \phi}, \\
z' &= \frac{a'}{(1 - e^2) \sin \phi'},
\end{align*}
\]

where \( \Delta = (1 - e^2 \sin^2 \phi), \Delta' = (1 - e^2 \sin^2 \phi'), \) and \( e \) is the eccentricity. Let \( f, g, h \) be the direction cosines of the normal to that plane which contains the normal at \( P \) and the point \( Q, \) and whose inclinations to the meridian plane of \( P = a, \) let also \( l, m, n \) and \( I', m', n' \) be the direction cosines of the normal at \( P, \) and of the tangent to the surface at \( P \) which lies in the plane passing through \( Q, \) then since the first line is perpendicular to each of the other two and to the chord \( k, \) whose direction cosines are proportional to \( x - x', y - y', z - z', \) we have these three equations

\[
f (x - x') + gy' + hz' = 0, \\
f' + gy' + hz' = 0, \\
(f' + z')^2 + y'^2 + z'^2 = 0.
\]

Eliminate \( f, g, h \) from these equations, and substitute

\[
\begin{align*}
l &= \cos \phi \quad f - \sin \phi \cos \alpha, \\
m &= \sin \phi \quad f' + \sin \phi' \cos \alpha, \\
n &= \sin \phi \quad f' - \sin \phi' \cos \alpha,
\end{align*}
\]

and we get

\[
(x - x') \sin \phi + y' \cos \phi = 0
\]

The substitution of the values of \( x, x', y', z', z' \) in this equation will give immediately the value of cot \( \alpha, \) and if we put \( \zeta \) for the corresponding azimuths on a sphere, or on the supposition \( \varepsilon = 0, \) the following relations exist

\[
\begin{align*}
\cot \alpha &= \cot \zeta = \cos \phi \cos \alpha, \\
\cot \alpha' &= \cot \zeta' = \cos \phi' \cos \alpha', \\
\alpha' \sin \phi - \alpha \sin \phi' &= \alpha \sin \omega.
\end{align*}
\]

If from \( Q \) we let fall a perpendicular on the meridian plane of \( P, \) and from \( P \) let fall a perpendicular on the meridian plane of \( Q, \) then the following equations become geometrically evident.

\[
\begin{align*}
\kappa &= \sin \mu \sin a = \frac{d}{\Delta} \cos \phi \sin \omega, \\
\kappa &= \sin \mu' \sin a' = \frac{d}{\Delta} \cos \phi' \sin \omega.
\end{align*}
\]

Now in any surface \( \omega = 0, \) we have

\[
\begin{align*}
k^2 &= -(x - x')^2 + (y - y')^2 + (z - z')^2 \\
- \cos \mu &= \frac{(x - x') \frac{du}{dx} + (y - y') \frac{du}{dy} + (z - z') \frac{du}{dz}}{k} \\
\cos \mu' &= \frac{(x' - x') \frac{du}{dx} + (y' - y') \frac{du}{dy} + (z' - z') \frac{du}{dz}}{k}
\end{align*}
\]

in the present case, if we put

\[
\begin{align*}
1 - \frac{\omega}{\omega} &= \frac{2U}{U} = \frac{1}{b}, \\
-k^2 &= 2U - \frac{\omega}{\omega} (x - x')^2 \\
\cos \mu &= \frac{a}{b} \frac{1}{U}, \\
\cos \mu' &= \frac{a'}{b} \frac{1}{U}.
\end{align*}
\]

Let \( \omega \) be such an angle that

\[
(1 - e^2) \sin \phi = \Delta \sin \omega \\
\cos \phi = \Delta \cos \omega,
\]

then on expressing \( x, x', z \) in terms of \( u \) and \( u', \)

\[
U = 1 - \cos \cos \cos \omega = \sin \omega = \sin \omega',
\]

also, if \( \omega \) be the third side of a spherical triangle, of which two sides are \( \omega - \omega \) and \( \omega - \omega' \) and the included angle \( \omega, \) being a subsidiary angle \( \phi' \) such that

\[
\sin \phi \sin \frac{\omega}{2} = \sin \frac{\omega - \omega'}{2} \cos \omega + \frac{\omega - \omega'}{2},
\]

we obtain finally the following equations—

\[
\begin{align*}
h &= \sin \phi \sin \frac{\omega}{2}, \\
\cos \mu &= \frac{a}{b} \sin \phi \sin \frac{\omega}{2}, \\
\cos \mu' &= \frac{a'}{b} \sin \phi \sin \frac{\omega}{2}, \\
\sin \mu \sin \omega &= \frac{a}{b} \sin \omega \sin \omega, \\
\sin \mu' \sin \omega &= \frac{a'}{b} \sin \omega \sin \omega.
\end{align*}
\]

These determine rigorously the distance, and the mutual zenith distances and azimuths, of any two points on a sphere whose latitudes and difference of longitude are given.

By a series of reductions from the equations containing \( \zeta \) it may be shown that

\[
a + a' = \zeta + \frac{1}{4} (\phi' - \phi) \cos \phi' \sin \phi + \ldots
\]

where \( \phi \) is the mean of \( \phi \) and \( \phi', \) and the higher powers of \( \phi \) are neglected. A short computation will show that the small quantity on the right-hand side of this equation can never amount even to the tenth thousand part of a second, and practically speaking is zero; consequently the sum of the azimuths \( \alpha + \alpha' \) on the sphere is equal to the sum of the spherical azimuths, whence follows this very important theorem (known as Laplace's theorem). If \( \phi, \phi' \) be the latitudes of two points on the surface of a sphere, \( \omega \) their difference of longitude, \( \alpha, \alpha' \) their reciprocal azimuths,

\[
\tan \omega = \frac{\cos \phi \cos \phi'}{\cos \phi' \sin \phi + \ldots}
\]

The vertical plane at \( P \) passing through \( Q \) and the vertical plane at \( Q \) passing through \( P \) cut the surface of the sphere in two distinct curves. The greatest distance apart of these curves is, if \( \omega \) be the mean azimuth of \( PQ, \)

\[
\frac{z}{b} \cos \phi \sin \omega = A \omega.
\]

This is a very small quantity, for even in the case of a line of 100 miles in length having a mean azimuth \( \omega = 45^\circ \) in the latitude of Great Britain, it will only amount to half an inch, whilst for a line of fifty miles it cannot exceed the sixteenth part of an inch. The geodesic line joining \( P \) and \( Q \) lies wholly between these two curves. If we designate by \( P', Q' \) the two curves (the former being that in the vertical plane through \( P \)), then, neglecting quantities of the order \( \omega^2, \) where \( \omega \) is the angular distance of \( P \) and \( Q \) at the centre of the earth, the geodesic curve makes with \( \omega \) an angle equal to the angle it makes with \( Q \) at \( Q, \) each of these angles being a third of the angle of intersection of \( P \) and \( Q'. \) The difference of length of the geodesic line and either of the curves \( P, Q' \) is, \( \omega \) being the length of either,

\[
\frac{1}{b} \frac{\sin \omega}{\omega} \cos \phi \sin \omega = 2A
\]

At least this is an approximate expression. Supposing the angle \( PQ \) to be as much as \( 10^\circ, \) this quantity would be less than one hundredth of an inch

An idea of the course of a geodesic line may be gathered from the following example. Let the line be that joining Cadiz and St Petersburg, whose approximate positions are

<table>
<thead>
<tr>
<th>City</th>
<th>St Petersburg</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lon.</td>
<td>6° 18' W.</td>
</tr>
<tr>
<td>Lat.</td>
<td>36° 22' N.</td>
</tr>
</tbody>
</table>

If \( G \) be the point on the geodesic corresponding to \( F \) on that one of the plane curves which contains the normal at Cadiz (by "corresponding" we mean that \( F \) and \( G \) are on a meridian) then \( G \) is to the north of \( F; \) at a quarter of the whole distance from Cadiz GF is 458 feet, at half the dis-

---

1 See a paper "On the course of Geodesic Lines on the Earth's Surface" in the Philosophical Magazine for 1870.
The azimuth of a more important place is the azimuth

The azimuth of a more important place is the azimuth of the geodesic line at the intersection of the meridian line with the parallel of latitude. The azimuth of the geodesic line at the intersection of the meridian line with the parallel of latitude. The azimuth of a meridian line is always more important than the azimuth of any geodesic line.

If $\alpha$, $\beta$, and $\gamma$ be the angles made by the direction of $Z$ with the sides $AB$ or $AC$ of the first triangle, then, to find $\phi_1$, where the line cuts the next triangle, we must make the angles $F\beta, F\alpha, B\phi_1$, such that $\rho F\beta + \rho B\phi_1 = 180^\circ$. This fixes $P_1$, and $P_2$ is fixed by a repetition of the same process, so for $P_1, P_2, \ldots$. Now it is clear that the points $P_1, P_2, \ldots$ are connected by a chain of triangles, and for $P_1$, $P_2$, $P_3$, and $P_4$, the chain of triangles is continually continued.

From the relation we have given above, expressing the mutual relations of points $P$, $Q$, on a sphere, we may obtain the solution of the problem. Given the latitude $\phi$ of $P$, with the azimuth $\alpha$ and distance $s$ of $P$, to determine the latitude and longitude of $Q$ and the back azimuth $\alpha'$.

Let

$$\theta = \frac{s}{a}$$

and

$$\zeta = \frac{\phi - \alpha}{\sin s}$$

$\zeta$ is always a finite quantity even for the longest distances, then, putting $s = 90^\circ - \phi$,

$$\tan \frac{s'}{2} = \sin \left(\frac{\pi}{2} - \frac{s}{2}\right) = \frac{\sin \left(\frac{s}{2}\right)}{\cos \left(\frac{s}{2}\right)}$$

$$\tan \frac{\phi - \alpha}{2} = \sin \left(\frac{\phi - \alpha}{2}\right) = \frac{\sin \left(\phi - \alpha\right)}{\cos \left(\phi - \alpha\right)}$$

$$\phi - \alpha = s = \sin s' = \sin \left(\frac{\phi - \alpha}{2}\right)$$

Here $\rho$ is the radius of curvature of the meridian for the mean latitude $\phi + \phi'$. These formulæ are approximate only, but they are sufficiently precise even for very long distances.

Meridian Arcs.

The length of the arc of meridian between the latitudes $\phi_1$ and $\phi_2$ is

$$s = 2\pi r \rho = 2\pi \rho \phi_1 (1 - \rho^2 \sin^2 \phi_1)^{-\frac{1}{2}}$$

instead of using the excentricity, put the ratio of the arcs $= 1 - \rho^2 \sin^2 \phi_1$, then

$$s = 2\pi r \rho \frac{1 + n x (1 + n x - 1)^{-1}}{(1 + 2a \cos 2\pi + e^2)}$$

Thus, after integration, gives

$$\tan \left(\frac{\phi - \phi_1}{\phi_1}\right) = \tan \left(\frac{s}{a}\right)$$

The part of $s$ which depends on $n$ is very small, in fact, if we calculate it for the longest arc measured, the Russian arc, it amounts to only an inch and a half, therefore we omit this term, and put

$$s = \frac{(n + \frac{1}{4}) a}{2}$$

Now, if we suppose the observed latitudes to be affected with errors, and that the true latitudes are $\phi_1 + x_1$, $\phi_2 + x_2$, and if further we suppose that $n_1 + x$ is the true value of $\phi_1 + x_1$, and that $n_2$ is the true value of $\phi_2 + x_2$, and that $n_1$ and $n_2$ are not very far apart, and are connected by a line of long distance and reciprocal lengths.

The azimuth of a meridian line is always more important than the azimuth of any geodesic line.

In determining the figure of the earth from the arcs of meridian measured in different countries, one source of uncertainty was, until the last few years, the want of comparison between the standards of length in which the arcs were expressed. This has been removed by the very extensive series of comparisons recently made at Southampton (see Comparisons of Standard of Length of England, France, Belgium, Prussia, Russia, India, and Australia, made at the Ordnance Survey Office, Southampton, 1866, and a paper in the Philosophical Transactions for 1873, by Lt.-Col. A. R. Clarke, C.B., R.E., on the further comparisons of the standards of Austria, Spain, the United States, Cape of Good Hope, and Russia). These direct comparisons, which were carried out with the highest attainable precision, are of very great value. The length of the base has three independent determinations, viz., through the Russian standard, the French geoid, and the Belgian geoid, giving for the length of the base, expressed in terms of the standard yard of England.
The latitude assigned in this table to Saxanford is not the directly observed latitude, which is 60° 49' 35' 53", for there are here a cluster of three close latitudes which are astronomically determined, and if we transfer, by means of the geodetic connection, the latitude of *Girth of Sea* to Saxanford, we get 60° 49' 36' 59", and if we similarly transfer the latitude of *Baltic*, we get 60° 49' 35' 46". The mean of these three is that entered in the above table.

For the Indian arc in long. 77° 40' we have the following data.

<table>

</table>

Having now stated the data of the problem, we may either seek that ellipsoid which best represents the observations, or we may restrict the figure to one of revolution. It will be convenient to commence with the assumption of an ellipsoidal figure, as on so doing we can, by a slight alteration in the equations of minimum, obtain also the required figure of revolution. It may be remarked that, whatever the real figure may be, it is certain that if we presuppose it an ellipsoid, the arithmetical process will bring out an ellipsoid, which ellipsoid will agree better with all the observed latitudes than any spheroid would, therefore we do not prove that it is an ellipsoid; to prove this, arcs of longitude would be required. There is no doubt such arcs will be shortly forthcoming, but as yet they are not available.

The first thing that occurs to one in considering an ellipsoidal earth is the question, What is a meridian curve? It may be defined in different ways: a point moving on the surface in the direction astronoanically determined as "north" might be said to trace a meridian; or we may define it as the locus of those points which have a constant longitude, whose zeniths lie in a great circle of the heavens, having its poles in the equator; we adopt this definition. Let \( a, b, c \) be the semiaxes, \( c \) being the polar semiaxis.

The equation of the ellipsoid being

\[
\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1.
\]

If \( P \) be any point on the surface, the direction cosines of the normal at \( P \) are proportional to...
and if \( \frac{1}{2} \pi - \phi \) be the angle between this normal and the minor axis, so that \( \phi \) is the latitude of \( P \), we have

\[
\sin \phi = \frac{z}{\sqrt{a^2 - x^2 + y^2}}.
\]

Hence the equation to a "parallel" in which the latitude \( \phi \) is constant is

\[
x^2 + y^2 + \frac{z^2}{a^2 - \cos^2 \phi} = \frac{a^2}{a^2 - \cos^2 \phi}.
\]

So that in an ellipsoidal earth the parallel is no longer a plane curve. Let longitude be reckoned from the plane of \( xz \). As there are two species of latitude, astronomical and geocentric, so there are in the ellipsoidal earth two species of longitude, geocentric (called \( w \)) and astronomical (called \( \omega \)). Conceive a line passing through the origin in the plane of the equator and directed to a point whose longitude is \( \frac{1}{2} \pi + \omega \). The direction cosines of that line are \(-\sin \omega, \cos \omega, 0\). Those points of the surface whose normals are at right angles to this line are in the meridian whose longitude is \( \omega \), the condition of perpendicularity is expressed by

\[
\sin \omega + y \cos \omega = 0,
\]

and thus, in fact, is the equation of the meridian, which is still on the ellipsoidal hypothesis a plane curve. The geocentric and astronomical longitudes are connected by the relation

\[
a^2 \tan \frac{\omega}{2} = b^2 \tan \omega.
\]

This meridian curve is an ellipse whose minor semi-axis is \( c \), and of which the semi-major axis is some quantity \( r \) intermediate between \( a \) and \( b \), such that

\[
1 - \frac{\cos^2 \omega}{a^2} = \left(1 - \frac{\cos^2 \omega}{b^2}\right) \cdot \frac{\cos^2 \omega}{b^2}.
\]

Take two quantities \( u, v \), such that \( a(1-u)=b(1+v)=k^2 \), then

\[
\frac{u}{1-u} = \frac{1}{1+v}.
\]

and substitute the value of \( r \), neglecting the square of \( s \), this gives

\[
\frac{u}{1-u} = \frac{1}{1+v} = \frac{4}{k^2}.
\]

Now we have to determine not only the three semi-axes \( a, b, c \), but the longitude of \( P \). Let \( \alpha \) be the longitude of one of the measured meridian arcs, \( \beta \) the longitude of another, then for that arc,

\[
\frac{u}{1-u} = \frac{1}{1+v} = \frac{4}{k^2}.
\]

where \( 4p = \cos 2\alpha + \sin 2\alpha \), \( 4p = \sin 2\beta \).

The normal at \( P \) does not pass through the axis of rotation, so that the observed latitudes on an ellipsoid are not exactly the quantities which should be used in the ordinary method of expressing the length of a meridian arc in terms of the latitudes. But it may be shown that this consideration may be neglected.

The data we have collected form 35 equations between the 40 z-corrections to the observed latitudes, and the four unknown quantities determining the elements of the ellipsoid. Suppose \( m_t \) to be an approximate value of the ratio \( k - c : k + c \), so that

\[
k - c : k + c = m_t + r,
\]

where \( r \) is a small correction to \( m_t \), and suppose \( c_2 \) to be an approximate value of \( c \) so that \( c = c_1 (1 + t) \), then the four unknown quantities are \( p, q, r, t \). The result of making the sum of the squares of the 40 corrections a minimum is

\[
a = 20956350 = 6378140 \quad b = 20919773 = 6378140 \quad c = 63560681
\]

The meridian of the greater axis passes, in the Eastern Hemisphere, through Spitzbergen, the Straits of Messina, Lake Chad in North Africa, and along the west coast of South America, nearly corresponding to the meridian which passes over the greatest quantity of land in that hemisphere. In the Western Hemisphere it passes through Behring's Straits and through the centre of the Pacific Ocean. The meridian (105° 34' E) of the minor axis of the equator passes near North-east Cape on the Arctic Sea, through Tongking and the Straits of Sundra, and corresponds nearly to the meridian which passes over the greatest amount of land in Asia, and in the Western Hemisphere it passes through South Sound, the west of Labrador, Montreal, between Cuba and Hayti, and along the west coast of South America, nearly coinciding with the meridian which passes over the greatest amount of land in that hemisphere.

The length of the meridian quadrant passing through Paris, in the ellipsoidal figure given above, is 10001472.5 metres, showing that the length of the ideal French standard is considerably in error as representing the ten-millionth part of the quadrant. The minimum quadrant, in longitude 105° 34', has a length of 10000516.5 metres. The probable error of the longitude of the major axis of the equator given above is of course large, as much perhaps as 15'.

It has been objected to this figure of three unequal axes that it does not satisfy, in the proportions of the axes, the conditions brought out in Jacobi's theorem. Admitting this, it has to be noted, on the other hand, that Jacobi's theorem contemplates a homogeneous fluid, and this is certainly far from the actual condition of our globe, indeed the irregular distribution of continents and oceans suggests as possible a sensible divergence from a perfect surface of revolution.

If we limit the figure to be an ellipsoid of revolution, we get rid of our equations of two unknown quantities, and the result may be expressed thus

\[
\frac{a - c}{a + c} = \frac{b - c}{b + c} = \frac{1}{2} = \frac{1}{2}.
\]

As might be expected, the sum of the squares of the 40 latitude corrections, viz., 153,99, is greater in this figure than in that of three axes, where it amounts to 138.30. In the Indian arc the largest corrections are at Dodagounth, +3° 87', and at Kalaupur, -3° 68'. In the Russian arc the largest corrections are +3° 77', at Tornera, and -3° 31', at Staro Nekrasowska. Of the whole 40 corrections, 16 are under 1° 0', 10 between 1° 0' and 2° 0', 10 between 2° 0' and 3° 0, and 4 over 3° 0. For the ellipsoidal figure the probable error of an observed latitude is \( 1° 42' \); for the spherical it would be very slightly larger. This quantity may be taken therefore as approximately the probable amount of local deflection.

In 1863, the Russian Government, at the instance of M. Otto Struve, imperial astronomer at St. Petersburg, invited the co-operation of the Governments of Prussia, Belgium, France, and England, to the important end of connecting their respective triangulations so as to form a continuous chain under the parallel of 52° from the island of Valaia on the south-west coast of Ireland, in longitude 10° 20' 40" W, to Omk on the river Ural in Russia. This grand undertaking was at once set in action, but up to the present
time there are portions of the work still incomplete. On
the part of England the triangulation was, in 1862, carried
through France into Belgium; and the difference of
longitudes of Greenwich and Valletta was determined by
the Astronomer Royal by means of electric telegraph signals.

Although in theory the determination of differences of
longitudes by electric telegraph signals may appear extremely
simple, yet practically there are very many sources of error
which have to be sought out and eliminated by a proper
arrangement of the observations. The system has now
been brought to such perfection that the astronomical
accuracy of arcs of longitude can be determined with
nearly as much accuracy as the figure of latitude, and in a few
years the data of the problem of the figure of the earth will
thus receive many additions. As an example of the
precision arrived at, the difference of longitude of Green-
wich Observatory and Harvard Observatory, U.S.A., has
been three times determined with the following results :-

<table>
<thead>

But the different determinations of the velocity of
transmission of signals present great anomalies.

**Pendulum Observations.**

In Clairaut's theorem we have seen that if $g'$ be gravity
in the latitude of $\phi$, $g$ its value at the equator, then
$g = g(1 + q \sin^2 \phi)$. If the same pendulum be swung in
different latitudes than the square of the number of
vibrations will be proportional to gravity. Hence, if $N$ be
the number of vibrations of an invariable pendulum per
diem at the equator, $N'$ the number in latitude $\phi$, then
$N'^2 = N^2(1 + q \sin^2 \phi)$. Thus $g$ can be obtained by observa-
tions on the same pendulum in different latitudes, and since
$q = \frac{\sin \phi}{\sin \phi'} - 1$ and $\phi$ is known, $g$ will at once, follow. The
pendulum which makes 86400 oscillations per diem in London
is observed to lose 136 vibrations at the equator and
gain 79 at Spitzbergen.

The limits of space at our disposal here prevent our going
into the subject of pendulum experiments, and it seems
unnecessary to repeat the investigations that have
already been based upon the older pendulum observations.

See Airy's *Figure of the Earth*, Baily's paper in the
Memoirs of the Royal Astronomical Society, General
Sabine's Account of Experiments to determine the Figure
of the Earth by means of the Pendulum vibrating seconds in
Different Latitudes, 1825, and a valuable paper in the
Cambridge Philosophical Transactions, 1849, by Professor
Stokes. The pendulum gives an ellipticity certainly some-
what greater than that resulting from arcs of meridian,

\[ \text{V} = \frac{1 - \cos \theta}{\cos \theta} \]

An immense number of pendulum observations are now being made at the astronomical stations of
goodscale surveys in Germany, Russia, and India, which,
when fully published, will throw light more perhaps upon
the local variations of gravity than on the figure of the
earth. The observations made at the various stations of
the Indian meridian are being light a physical fact of the
very highest importance and interest, namely, that the
density of the strata of the earth's crust under and in the
vicinity of the Himalayan Mountains is less than that
under the plains to the south, the deficiency increasing as
the stations of observation approach the Himalayas, and
being a maximum when they are situated on the range
itself. This accounts for the non-appearance of the large
deflections which the Himalayas, according to Archedeacan,
Fratt's calculations, ought to produce. The Indian
pendulum observations also throw some light on the relative
variations of gravity at continental, coast, and island
stations, showing that, without a single exception, gravity
at the coast stations is greater than at the corresponding
continental stations, and greater at island stations than
at coast stations. The ellipticity of the earth has also
been deduced from the motion of the moon, the quantity
$1 - \frac{1}{e^2}$ entering as a coefficient in the expression for
the moon's latitude. The resulting value of the ellipticity is
3.504 (Airy's True, p. 395). A value of the ellipticity
may also be derived from the precession of the equinoxes,
but this depends on the assumed law of density in the
interior of the earth it is not of much importance.

**Elements of the Figure as a Solid of Revolution.**

If $a$ be the radius of curvature of the meridian in latitude $\phi$, $\phi'$
that perpendicular to the meridian, $D$ the length of a degree of the
meridian, $D'$ the length of a degree of longitude, $r$ the radius drawn
downward from the centre of the earth, $\psi$ the angle of the vertical, then

\[ \begin{align*}
\psi &= \frac{20990500 - 1064115 \cos 2a + 225 \cos 4a}{0.13485 - 95.8 \cos 2a + 139.8 \cos 4a} \\
D &= \frac{384609 - 1857 \cos 2a + 394 \cos 4a}{0.13485 - 95.8 \cos 2a + 139.8 \cos 4a} \\
D' &= \frac{385538 - 48 \cos \phi - 310 \cos 2a + 253 \cos 5a}{0.13485 - 95.8 \cos 2a + 139.8 \cos 5a} \\
\psi &= \frac{9 9996245 - 11000284 \cos 2a - 8000109 \cos 4a}{0.13485 - 95.8 \cos 2a + 139.8 \cos 4a} \\
\psi &= \frac{7004 \sin 2a \cos 25 \pi}{0.13485 - 95.8 \cos 2a + 139.8 \cos 4a}.
\end{align*} \]

In this country, the earliest work worthy of mention is Dr. Robert Hooke’s *Discourse on
Earthquakes*, written in 1668, and read at a later date
before the Royal Society. This discourse, though containing
many passages of considerable merit, tended but little to
a correct interpretation of the phenomena in question.

In this country, the earliest work

\[ \psi = \frac{99996245 - 11000284 \cos 2a - 8000109 \cos 4a}{0.13485 - 95.8 \cos 2a + 139.8 \cos 4a} \]

\[ \psi = \frac{7004 \sin 2a \cos 25 \pi}{0.13485 - 95.8 \cos 2a + 139.8 \cos 4a} \]

\[ \psi = \frac{99996245 - 11000284 \cos 2a - 8000109 \cos 4a}{0.13485 - 95.8 \cos 2a + 139.8 \cos 4a} \]

\[ \psi = \frac{7004 \sin 2a \cos 25 \pi}{0.13485 - 95.8 \cos 2a + 139.8 \cos 4a} \]

\[ \psi = \frac{99996245 - 11000284 \cos 2a - 8000109 \cos 4a}{0.13485 - 95.8 \cos 2a + 139.8 \cos 4a} \]

\[ \psi = \frac{7004 \sin 2a \cos 25 \pi}{0.13485 - 95.8 \cos 2a + 139.8 \cos 4a} \]

\[ \psi = \frac{99996245 - 11000284 \cos 2a - 8000109 \cos 4a}{0.13485 - 95.8 \cos 2a + 139.8 \cos 4a} \]

\[ \psi = \frac{7004 \sin 2a \cos 25 \pi}{0.13485 - 95.8 \cos 2a + 139.8 \cos 4a} \]
His illustration of the movement of the ground is that of a loose carpet thrown into undulations by being shaken at one corner. Although Michell's hypothesis is still accepted, in a modified form, by some geologists, it should be remembered that many arguments of considerable weight have been urged by modern physicists against the doctrine of a liquid nucleus and a thin crust. Whatever the merits of Michell's theory, he failed to understand the true nature of wave-motion, and the way in which it is transmitted during an earthquake shock. Modern seismologists believe that an earthquake is a vibratory motion propagated through the solid materials of the earth, much in the same way that sound is propagated by vibrations in the atmosphere. It appears that this view was first suggested by Dr Thomas Young in his Lectures on Natural Philosophy, published in 1807. The development of this view, especially in its quantitative results, lies at the very base of seismology.

In 1846 Mr Mallet communicated to the Royal Irish Academy his first paper "On the Dynamics of Earthquakes," and in the following year the late Mr Hopkins, of Cambridge, presented to the British Association a valuable report in which earthquake-phenomena are discussed in some detail. Since that date the great advances in this country have been made by Mr Mallet, assisted occasionally by the Rev. Professor Haughton and other mathematicians.

Even at the present day, after all that has been written on the subject, but little is really known as to the origin of earthquakes. Probably several distinct causes should be recognized, for it is hardly to be supposed that all subterranean disturbances, differing as they do so widely in intensity and in duration, should be referable to one common mechanism. Any great concussion, even upon the surface, is competent to produce tremors which may be regarded as diminutive earthquakes; thus the great land-slip at the Rossberg in Switzerland in 1806 was accompanied by a local quaking of the ground. Volger and Mohr have suggested that some of the small earthquakes which have been felt in Germany may be referred to the falling-in of the roof of enormous subterranean cavities formed by the long-continued solvent action of water on deposits of rock-salt, limestones, and gypsum. Such causes, however, can have given rise to only very petty shocks, and must be quite subordinate to subterranean disturbances of a more general character. The late Mr Poullart Scrope was led to refer most earthquakes to "the snap and jar occasioned by the sudden and violent rupture of solid rock-masses, and perhaps the instantaneous injection into them of intumescent molten matter from beneath." He believed that the rupture of the rocks was due to expansion of deeply seated masses of mineral matter, consequent upon either increased temperature or diminished temperatures. It is argued, however, by Mr Mallet, on mechanical principles, that such fractures could produce only very weak impulses; but he believes that some earthquakes, especially those marked by long continued tremors, may be due to the movement and crushing of rock masses by tangential pressures produced by secular cooling of the earth. Steam has always been a favourite agent with seismologists, since it is clearly competent to produce great effects by its sudden generation or by its sudden condensation. It has been suggested that water, finding its way through fissures in the earth's crust, might reach the heated rocks in a vapourous or subaqueous condition, until a local reduction of temperature suddenly caused it to flash into steam. After all, the origin of earthquakes is probably to be regarded as part only of a much wider question. Whatever causes are competent to produce volcanic action are, in all likelihood, equally competent to produce the ordinary manifestations of seismic energy. A relation is clearly traceable between the geographical distribution of volcanoes and the chief earthquake-areas, and although it is not for a moment to be supposed that the volcano and the earthquake stand to each other in the relation of cause and effect, it is nevertheless highly probable that they represent merely different expressions of the same subterranean forces.

Whatever may be the real origin of the earthquake shock, it is convenient to regard its effects as proceeding from a concussion or sudden blow delivered underground at some definite centre. This centre of impulse is called the "seismic focus." It must be borne in mind, however, that such a centre, so far from being anything like a mathematical point, is in nature a subterranean region, which in many cases is no doubt of very large dimensions, measuring perhaps some miles in diameter.

From the seismic centre waves are propagated in all directions through the solid materials of the earth's crust, and if the focus be situated beneath the sea, the vibrations of the ground will be accompanied by undulations of the water. Those waves which pass through the elastic materials of the earth consist of two parts, of longitudinal vibrations, like those of atmospheric sound-waves, and consequently not like ordinary water-waves. In the sound-wave the air is alternately condensed and rarefied, the molecules advancing and retreating in the line of direction in which the wave is travelling. In the water, on the contrary, the molecules of liquid rise and fall, or rather describe closed curves in planes which are transverse to the direction in which the undulation or wave-form advances. According to Mr Hopkins, both orders of vibration—longitudinal and transverse—occur in the earth-quake-wave, and call for investigation. When, for example, the molecules of an iron bar are disturbed by a blow delivered at one end, both kinds of vibration are generally excited, and hence two waves are sent through the bar,—the longitudinal, however, having a much greater velocity than the transverse wave. But it may be doubted whether the seismologist need concern himself with any but longitudinal vibrations.

For, admitting that small transversal vibrations are generated at the seismic focus, it is probable that they would be cut off at a great extent during transmission from stratum to stratum. Indeed, the planes of junction between the several beds of stratified deposits would hinder the transmission of transversal vibrations travelling in a direction normal to the strata. Hence Mr Mallet maintains, that in studying the effects of an earthquake, attention may be usually, without danger of error, confined to the longitudinal or normal vibrations, the transversal or tangential vibrations being neglected.

Around the seismic centre, or mean focal point, the molecules of the rock will first be squeezed together by the concussion, and then separated by virtue of the elasticity of the solid medium, the onward motion is then rapidly taken up by the next set of molecules, which in like manner are pushed against one another, and then spring apart. In this way the pulse, or form of the wave, may be propagated to an enormous distance, whilst the excursions of the individual particles are confined within very narrow limits. It is therefore of great importance to distinguish between the transit of the wave and the movement of the material particles. Each molecule may move only through a few inches, but the undulation may travel for hundreds of miles. The distance through which the individual particles oscillate is called the amplitude of the wave. After the Neapolitan earthquake of 1857 Mr Mallet found from actual observation at a place called Polia, situated nearly above the seismic centre, that the amplitude of a wave which continued for some 2½ miles was less than an inch. He is thus led to believe, contrary to the opinion of most geologists, that earthquakes are not great agents of...
permanent elevation. That elevation has been frequently observed after an earthquake is a fact beyond question; thus, Captain Fitzroy found, after the South American earthquake of 1855, that a part of the isle of Santa Marta in the Bay of Concepcion, had been raised upwards of 10 feet, and, although this elevation was followed by a slow subsidence, it is believed that the land was permanently lifted considerably higher than its level before the occurrence of the catastrophe. Mr Mallet, however, would prefer such alteration of level to the action of elevatory forces accompanying the earthquake, but not to the direct transit of the earth-wave.

From the density and the modulus of elasticity of a given rock, it is possible to calculate the velocity with which a vibration would travel through such a medium. But the rate deduced by calculation usually exceeds very greatly that actually observed in an earthquake. To determine the rate of transit through various rocks, Mr Mallet and his son Dr J. W. Mallet conducted many years ago a series of experiments, at the instance of the British Association. A mile was carefully levelled and measured on sand in Killiney Bay, near Dublin, and by explosion of gunpowder the velocity of transmission through this damp sand was observed. This sand was selected as a medium likely to give a minimum velocity, whilst an assumed maximum velocity was observed by experiments on the granite of Killiney Hill. The velocity in sand was about 825 feet, and in solid granite 1665 feet per second. These figures are much lower than those obtained from theoretical considerations, and it is believed that the difference is due to loss of speed occasioned by the discontinuity of the rock, even the solid granite being always more or less affected by fomentation. The velocity deduced from these experiments accords tolerably well, however, with that observed during earthquake-shocks. Thus the velocity of shock during the Lisbon earthquake of 1755 is computed to have been about 20 miles per minute, or 1760 feet per second. This velocity of the earth-wave, or wave of shock, is of course to be carefully distinguished from the velocity of the oscillating particles. The mischief of the shock depends in fact on the rate at which the earth-molecules are moving, and this is vastly inferior to that of the wave. Thus Mr Mallet calculated from his observations in Naples that the shock of the great earthquake of 857 had a mean velocity in the surface of 788 feet per second, whilst the greatest velocity of the wave-particles was never more than 15 feet per second, and in many places was very much less. Yet this low velocity is quite sufficient to produce effects of the most disastrous kind upon solid objects exposed to the shock.

If the earth were a homogeneous solid, perfectly isotropic — that is to say, possessing equal elasticity in all directions — the waves of alternate compression and expansion would take the form of a series of concentric spherical shells around the seismic focus as a common centre. As a matter of fact, however, the crust of the earth is made up of rocks varying greatly in physical properties, each having its own density and elasticity, whilst the rocks themselves are fissured in all directions. Symmetry of wave-surface is therefore hardly to be expected; for the waves will necessarily have greater velocity in one direction than in another, whilst the transit of the wave may be interrupted by breach of continuity in the transmitting medium. The points at which a wave-shell reaches the surface form a curve which is conveniently called a coseismic line. It is obviously the line along which an earthquake shock will be simultaneously felt, and where the waves will emerge at the same angle. Since the wave-shells are not concentric spheres, the coseismic curves cannot be concentric circles.

It may readily be supposed that the greatest effect of an earthquake, at least in shaking a building up and down, will be felt at that point of the surface which is situated vertically over the centre of impulse. A line joining this point with the earthquake-focus is termed the coseismic vertical, and the wave travelling to the surface along this vertical has a shorter path than that of a wave emerging at any other point. Just as the seismic focus is, in nature, not a single point, but a considerable space, so the seismic vertical is not a single line, but rather a succession of parallel lines drawn from every point of the focal area to the surface. The mean of these lines may be taken as the seismic vertical. In the neighbourhood of this line the waves emerge at very steep angles, and indeed for a considerable area may be regarded as practically vertical in direction. As the distance from the seismic vertical increases, the angle of emergence becomes less and less; but it is evident that since the focus is seated beneath the surface, the path of an emergent wave can never be perfectly horizontal, unless indeed it be that of a reflected wave.

Almost any object which has been overthrown or projected by an earthquake-shock may afford direct information as to the path of the wave on the surface. For when the vibration is transmitted to such a solid body as an upright column, the particles are pushed together and then pulled apart in the line of wave-transit. It is clear that only half the energy of the wave can be propagated in the same direction as that in which the wave is travelling, and half in the opposite direction. Each particle of the object when first disturbed moves with the wave, and its velocity increases from zero to the maximum, this maximum being reached at one quarter of the total vibration; then the velocity diminishes from the maximum to zero, which it attains at the end of half the oscillation. During this first semi-phase, therefore, the vibration has been in the direction in which the wave moves. After the first half oscillation has been executed, movement begins afresh, but this time in the contrary direction, attaining its maximum at the end of the third quarter, and then falling again to zero when the vibration is completed. Hence during the first semi-phase, the motion of the particles is in the same sense or direction as that of the wave, and during the second semi-phase in the opposite direction. But in consequence of the inertia of the body its apparent movement if free, will be in a direction contrary to that of the wave during the first semi-phase. Whatever the direction of the shock, however, it will always be in the line of wave-transit. Hence the azimuthal direction of the wave is easily found.

Whenever any two wave-paths, not in the same right line, can be thus traced on the surface, the position of the seismic vertical may be immediately determined. For thus line must pass through the point of their intersection. If, for example, it is found by observation on bodies displaced by the shock that one wave moved in the direction AB (Fig. 1), whilst another had a path CA (Fig. 1), it is only necessary to mark on the surface the point O, at which these azimuths meet, and the seismic focus will be vertically beneath such a point. The point indicates, in fact, the centre on the surface from which the waves radiated. Practically it is found that the several wave-paths of an earthquake do not diverge from a single point, for reasons already indicated; but intersections are less and less, and the paths are crowded together in the neighbourhood of the mean vertical. It is easy to understand that the greatest amount of mechanical damage is not to be expected immediately above the focus, although this is the point nearest to the origin of impulse. It is true, the shock passing directly upwards along the seismic vertical might destroy the roof or floor of a building, but it would not tend directly to overturn the walls or produce lateral disturbance. In fact, the side-thrust will be greatest in waves which reach the surface at small angles, and are therefore necessarily at great distances from the seismic vertical. But the energy of the wave diminishes as the square of the distance along the normal increases. Hence there must be some definite position upon the surface beyond which advantage of direction is counteracted by loss of energy. Indeed it is generally possible after an earthquake to trace the successive zones of objects may be regarded as practically the same are known as "seismic curves". After what has been already said, it is hardly necessary to remark that these lines are not true circles, nor indeed are they in all cases regular closed curves.

Fig. 1.
Fractures and fissures in walls which have been rent by an earthquake, are of great value to the seismologist, since they often indicate the direction in which the waves emerge at the surface. The interpretation of such phenomena, in some cases very complicated, has been ably discussed by Mr Mallet, who applied the results with excellent effect to his observations on the Neapolitan earthquake. If it is possible to find, from such indications, the direction in which any two waves emerged at the surface, the depth of the seismic focus is easily determined. For since the waves radiate from this focus, any two wave-paths when produced backwards will meet at the seismic centre. It has already been shown that the verticals are so situated that, when this is known the direction of the focus is determined, for as the verticals represent one wave path it is necessary to find only one other. Let O (fig 2) be the seismic focus, and OA the seismic vertical, if a

**Fig 2.**

wave, OB, emerge at the surface B, at an angle θ, it is evident that

$$AO = AB \tan \theta$$

To find the depth of the focus, it is consequently only necessary to know the angle of emergence of a wave at a given station, and the distance of this station from the seismic vertical. As the stations are so situated that, for each other, the earth's sphericity may be neglected, and the surface between the two regarded as practically a horizontal plane,

where several wave-paths are known, several values of AO will be obtained, and as the seismic centre is not a point, like O, but a cavity of determinate magnitude, the average of these different values must be taken to represent the mean focal depth. After the great Neapolitan earthquake of 1857, Mr Mallet, aided by the Royal Society, spent months in carefully examining the country which had been rent by the shock, and in 1852 he published an elaborate report in which his observations were fully discussed. By determining the wave-paths at twenty-five stations in every azimuth around the seismic vertical, he was enabled to deduce the important fact that the mean focal depth of the earthquake was about 12 geographical miles. Similar principles have since been applied by Dr Oldham to an examination of the results of an earthquake which occurred in Cachar in India, on January 10, 1869, and he has found that the seismic focus must have had a depth of about 30 miles.

Between the centre of disturbance and the seat of the shock, as appears to have been the case with that which produced the great earthquake of Lisbon in 1755, a water-wave is generated, but since this has less velocity than the earth-wave, it does not roll up upon the shore until after the shock has been felt on land. The height of the sea-wave depends on the depth of the water. During the Lisbon earthquake the wave at Cadiz was as much as sixty feet in height. It is this great sea-wave which, breaking upon the shore after the earthquake-shock, generally completes the work of devastation. At first the water retires from the land, but in a few moments the gigantic wave rolls in, and sweeps all before it.

The earthquakes which are so frequently felt on the western coast of South America are generally terminated in this manner, and the great tube wave which accompanied the earthquake of May 1877, wrought dreadful havoc at Arica, Iquique, and other towns on the coast. In addition to the waves propagated through earth and sea, it commonly happens that waves are transmitted through the air and thus produce sound. These sound-waves, travelling at the rate of about 1100 feet per second, may reach the observer nearer simultaneously with the shock or before it or even after it. They probably result from sudden fracture and dislocation of rock-masses, or from subterranean explosions.

Almost every object disturbed by an earthquake may be made to yield, when properly questioned, more or less information with respect to the direction and intensity of shock. Special instruments termed seismometers, however, have been constructed for this purpose, and have assumed considerable variety of form. Perhaps the simplest seismometer is that suggested by Mr Babbage, consisting merely of a bowl of some vessel liquid like treacle. On the passage of a shock the liquid rises up one side of the vessel, leaving its mark to indicate radially the direction and extent of motion. As a modification of this simple instrument Mr Mallet proposed the use of a common wooden tub having its inside rubbed with chalk, and half filled with coloured water. An apparatus devised by Professor Cescutore, of Palermo, and much used in Italy, is constructed with a shallow dish having eight notches in the side, and containing mercury up to the level of the lip. When any oscillation occurs, the liquid is split into a series of caps placed under the notches, and the quantity ejected, which may be readily weighed, gives some notion of the intensity of the shock. Since the notches face the four cardinal points and bisecting rhumbs, the direction in azimuth is approximately obtained. Mr Mallet suggested a convenient form of seismometer in the shape of a tube, the cavity of which is filled with mercury, and the horizontal limb directed to the cardinal points. The tube is partially filled with mercury, and the horizontal component of any shock causes the mercury to move in the lower limb, whilst the vertical component is determined by the motion of quicksilver in a U-shaped tube. In both cases, the movement of the liquid column is registered by means of indexers.

All these instruments depend for their indications on the displacement of liquids by the shock of the earthquake. But it is obvious that the oscillations of solid bodies may be equally well employed in seismometry. Thus a pendulum free to move in all directions will be set vibrating by a shock, and may be made to record the direction and extent of its vibration by means of a style below the bob, which moves over a bed of fine sand in a properly-shaped dish. Two pendulums are sometimes used, as proposed by Santu. One pendulum vibrates in a vertical plane directed north and south, and the other in one striking east and west. The axes traced by these styles are registered by means of a tracing-stile affixed to the bob. Professor J. Forbes employed an inverting pendulum, or rod fixed at its base and weighted above, carrying at its free end a pencil or tracer by which any oscillation could be recorded. A modification of the inverting pendulum was devised by Mr Mallet, and described in 1849. Both the horizontal and the vertical element of a shock are recorded by the movement of mercury in a system of glass tubes, the tubes being placed in a galvanic circuit so arranged that contact is broken by displacement of the liquid. As long as the circuit remains complete, a pencil traces a line on ruled paper wound round a cylinder rotated by clock-work, but the motion of the mercury intercepts the current and thus breaks the line. Two forms of "ball seismometer" are also due to the ingenuity of the investigator. In one of these instruments, two heavy metal balls are placed on slightly inclined planes supported by a cast-iron table, the axis of which passes through a vertical
spiral spring. During the passage of an earthquake wave the spring is compressed and the balls displaced,—their displacement breaking contact in an electric circuit which had previously been completed through the balls. That ball which first moves gives the time at which the shock commences, whilst the other gives the elements of the shock. Two such instruments are necessary to form one seismometer, the two being placed at right angles to each other.

An elaborate electro-magnetise seismograph has been constructed by Professor Palmeri, and has done good service in the observatory on Mount Vesuvius. The vertical movements are recorded by a helix of copper wire, the lower end of which is caused by even the slightest shock to dip into a basin of mercury, and thus complete a galvanic circuit. An electro-magnet, brought into action when the connections are completed, strikes an alarm bell which calls an attendant, and also stops a clock, so that the instant at which the shock occurs is permanently marked. At the same time a second electro-magnet releases the pendulum of another clock, which being thus set in motion unrolls a band of paper, while a pencil continues to mark upon the paper as long as the shock lasts. To record the vertical element a system of four U-shaped tubes is employed, the same being partly filled with mercury, and any displacement breaking contact being placed at right angles to each other.

Fig. 3

Two sets of right cylinders are turned to fig. 3. Two such instruments connected with an index. The shock lasts to record the vertical displacement breaking contact which is caused by even the slightest shock to overtop No. 3 standmg; then the shock commences by connecting the narrow-based pillar with the pendulum of a clock so as to stop it at the instant of overthrow. Where the angle of wave-emergence is very steep, this instrument is not to be recommended, since it ignores the vertical element of the shock.

Catalogues of earthquakes, showing their distribution in time and space, have been constructed by Mallet, Perrey, Von Hoff, Cotte, and other seismologists. The most complete of these statistical works is the catalogue arranged compiled by Mr. R. Mallet and his son, Dr. J. W. Mallet, and published by the British Association between the years 1854 and 1858. This includes notices of all recorded earthquakes from 1608 a. d. to 1842 a. d. and in these was carried on to 1850 from Perrey's annual catalogues. Between 6000 and 7000 separate earthquakes are recorded as having occurred in most every part of the world, both on land and sea; though seismic energy may thus become sensible at any point of the earth's surface, there are, as everyone knows, certain regions peculiarly subject to earthquakes, and it is, in fact, from these seismic bands of variable width following the great lines of elevation which divide the oceanic basins.

It is a few years since Professor Alexis Perrey, of Dijon, sought to trace a relation between the occurrence of earthquakes and the age of the moon. By careful analysis of his catalogue he believed that he had established the fact that earthquakes are more frequently at the syzygies than at the quadratures, that their frequency increases at the perigee and diminishes at the apogee of the moon, and that shocks are more frequent when the moon is on the meridian than when 90° from it. Such a connection between seismic phenomena and the phases of the moon would accord with Zan tedeschi's views on the existence of a terrestrial or ferrous zone, views which were based, however, on the old hypothesis of a liquid nucleus in the earth, covered by a thick crust.

The cylinders stand upright on the planks in the order of their size, with a space between each pair greater than their height, so that when one pillar falls it does not strike its neighbour. The surrounding floor is covered to the level of the planks with dry sand. When a shock passes, some of the cylinders are overturned, the number depending on the velocity of the wave. Suppose the shock knocks over the narrow-based cylinders 4, 5, 6, leaving Nos. 1, 2, 3 standing; then the velocity of the horizontal component must have been greater than that needed to overturn No. 4, but great enough to overturn No. 3. Hence the velocity (V) can be approximately obtained by using a formula due to Professor Haughton, viz.:

\[
\theta = \frac{150\pi^2 + 16\pi^2}{125^2} \sqrt{v^2 + \frac{3}{2} \left(1 - \cos \theta \right)}
\]

where \(a\) is the altitude of the column, \(b\) the diameter of its base, and \(\theta\) the angle formed by the inclination of the column drawn through the centre of gravity to the extremity of the base. The direction in azimuth is indicated by the position in which the overturned pillars are found, since the bed of sand prevents rolling. It is possible to obtain the exact time at which the shock commences by connecting the narrow-based pillar with the pendulum of a clock so as to stop it at the instant of overthrow. Where the angle of wave-emergence is very steep, this instrument is not to be recommended, since it ignores the vertical element of the shock.

Annual reports on earthquakes have been published for many years by Professor Fuchs. During the year 1858 he recorded 104 earthquakes, which were distributed among the months as follows.—In January 10, February 10, March 14, April 8, May 7, June 7, July 8, August 5, September 7, October 14, November 5, December 9. In the preceding year 97 earthquakes were noted, occurring as follows.—In January 15, February 7, March 12, April 7, May 9, June 10, July 6, August 5, September 3, October 2, November 9, December 12.

error arising in the first instance probably from their invariable habit of secretting themselves in any cavity, of which they always endeavour to reach the innermost recess (instances being known of the common species hiding itself in the ear of a person sleeping in the open air), and strengthened by the popular exaggerated idea of the strength and attributes of the anal forceps peculiar to these insects.

Earwigs have been for some time of uncertain position in classification, having been ever considered as worthy of the rank of a separate and distinct family, Spaltotrepidae; Duncker, (Lobododera), Longhorn, (Dermatera), Dorsaloptera, Loven; and Euphotopterina, (Dutroct), (the Locustae, Grasshopper, Crickets, Cockroaches, Mantis, &c.) They have much the habits of the Brachytela or Stephysyphus in the Coleoptera (Beetles), from which order they differ in their paps being active, resembling the perfect insect except in possessing only rudimentary wings, &c.; also in the method of folding and seoration of the hinder wings, the presence of an anal forceps, and, as in the Orthoptera, in the external additional lobe to their maxilar. From all the other Orthoptera, apart from the anal forceps, they differ in having horizontal elytra covering the wings in repose in beetles, and in the female not possessing a cocoon scavenger, and from most of them in the hind legs being not formed for jumping.

Of distinct species 250 are recognized, comprised in 34 genera (of which some are apparently needless), but it is highly probable that the present range of the genus, as scarred by naturalists make them an object of study, and their geographical distribution is very extended. There are about 200 species in the collection of the British Museum alone, mostly unnamed, and not specially collected. They are found in the whole of Europe, in Syria, and Asia Minor, Ceylon, China, and Japan, the Malay Archipelago, the Philippine; North, West, and South Africa to the Cape itself, Egypt, Zanzibar, Mauritius, Ceylon, New Guinea, South Australia, Tasmania, and New Zealand, and species occur in such isolated localities as Madeira, the Canaries, St. Helena, Woodstock Island, the Sandwich, and the Sandwich Islands, and Kerguelen's Island. As regards pre-historic times, a few fossil species have been found in the territories of Solnhofen, Eicheng, in Italy and in the Old World, and of the Rocky Mountains (Colorado) in the New Seven species have been recorded from Great Britain, of which two are universally common, viz., Forficula auricularia, and the smaller Lobula minor. The former is found all over Europe, in Armenia, Ceylon, and other parts of Asia, and in the eastern United States, being also recorded from Japan, and the latter occurs in Europe, Western Asia, and North America. Another species, Lobododera tympany, extends over the entire Old World.

All are of comparatively small size, and nearly all of ob­scure colours, mostly various shades of brown or dull yellow, and of a much smaller size, one South American species is with another, from the Amazon, has blue metallic elytra, which are metallic also in another from Peru, a fourth exotic species is yellow, with black stripe, and several have opaline or irisdecent wings. Ectenaty development is shown chiefly in the forceps, which in a Nicaraguan species are as long as the rest of the body; in another South American form the abdomen is laterally toothed, a third has very long legs, being almost tipuline, Apachya has the body as thin as cardboard. Sexual differences are shown in the male by the greater development and armature of the forceps, or the tuberculated abdomen, which is composed of nine distinct segments, whereas only seven are evident in the female. The forceps have been observed to be used in arranging the wings, and are also supposed to be used as weapons of offence and defence, through it is difficult to understand how they could be of any practical assistance for either purpose. The lower wings have long attenuated appendage, and an unpaired organ of flight, Poceleria curricularia has seldom, if ever, been observed to make use of the wings, though there is evidence that it does fly, but the other common British species, Lobula minor, is frequently seen on the wing, being often mis­taken for a brachyleptous beetle. It may be observed that the possession of wings is apparently sexual in some cases, and that some species are entirely apetrous.

Some few instances have been recorded of earwigs being carnivorous, devouring the larvae and pupae of wild bees and even their own species; but the majority are in a normal state certainly eaters of vegetable matter, congregating under bark, and destroying flowers, fruit, &c., often to a considerable extent. An instance of their adaptability to circumstances is afforded by Mr. H. W. Bates's discovery of a large white species (above referred to) very common on white sandy beaches of the Brazilian river Para, at Carpó with a white Tetracha and a white mole cricket, this white­ness was permanent, and must not be confused with the light colour of recently disclosed individuals.

The female of the common earwig has long been noted for an exhibition of remarkable maternal instinct in defending her progeny, not only brooding over her eggs, but caring for her newly hatched young.

The chief writers on Forficula are Dobson, in the Straten exomologische Oekologie for 1863 and following years, and quite recently, S. H. Scudder, in the Proceedings of the Boston Natural History Society, vol. xiv., the latter being the first to express these insects in a collective form (P. E. B).

EASEMENT, in English law, is a species of servitude or limited right of use over land belonging to another. It is distinguished from a profit, which is a right to take the soil of another, while an easement is a right to use the soil or the produce of the soil in a way tending to the more convenient enjoyment of another piece of land. Thus a right of way is an easement, a right of common is a profit.

Besides rights of way the most important easements are water-courses (as where a person has a right to divert a flow of water), the right to discharge water, &c., upon a neighbour's land, and the right to restrain such a use of land as would obstruct the access of light and air to an ancient window.

EASTBOURNE, a watering-place on the Sussex coast, 66 miles from London by railway. It is situated about three miles inland to the east of Beachy Head, the flattest head land on the English Channel. It once consisted of three parts—the old village of East Bourne, a mile inland, South Bourne, lying back from the shore, and Seabournes, facing the beach, but these distinctions are now almost obliterated, and numerous handsome terraces and detached houses have more or less united the three old hamlets into one town. Besides the parish church of St. Mary's, a building of some antiquity, there are four chapels of ease in Eastbourne. A pier was erected in 1869. The population, which is rapidly increasing, was 10,361 in 1911.

EASTER, the annual festival observed throughout Christendom in commemoration of the Resurrection of our Lord Jesus Christ. The word Easter—Anglo-Saxon, Eastre, Easter, German, Ostern—like the names of the days of the week, is a survival from the old Teutonic mythology. According to Bede (De Temp. Ratu, c. xv.) it is derived from Eostre, or Ostara, the Anglo-Saxon goddess of spring, to whom the fourth month, answering to our April—thence called Easter-monath—was dedicated. This month, Bede informs us, was the same as the "Menus Paschala," when the old festival was observed with the gladness of a new solemnity."
The name by which Easter is known among the Romance nations—French paques; Italian, pasqua; Spanish, pascua—is derived through the Latin pascha, and the Greek paíka, from the Chaldean or Aramaean form, מִסְכָּה (misca), of the Hebrew name of the Passover festival, פֶּסַח, from פַּסַח, “he passed over,” in memory of the great deliverance when the destroying angel “passed over” the houses of the children of Israel in Egypt when he smote the Egyptians.” Exp. xii. 27. An erroneous derivation of pascha is given by some of the early fathers of the church, e.g., Irenæus, Tertullian, T càc., to whom Hebrew was an unknown tongue, from the Greek πάσχειν, “to suffer,” as being the period of our Lord’s sufferings. St. Augustine (in Joann. Tract. 56) notices this false etymology, and shows how similarity of sound had led to the error, and gives the true derivation.

There is no trace of the celebration of Easter as a Christian festival in the New Testament or in the writings of the apostolic fathers. The sanctity of special times or places was an idea quite alien from the early Christian mind, too profoundly absorbed in the events themselves to think of their external accidents. “The whole of time is a festival unto Christians because of the excellency of the good things which have been given, writes Chrysostom, commenting on the passage Col. v. 17, which has been erroscously supposed to refer to an apostolic observance of Easter. Origen also in the same spirit (Contr. Celsum, v. 22) urges that the Christian who dwells on the truths of Christ of our Presentation and the gift of the Holy Ghost, in every day keeping an Easter and Pentecostal feast. The ecclesiastical historian Socrates (Hist. Eccl. v. 29) states with perfect truth that neither Christ nor his apostles enjoined the keeping of any or any other festival. “The apostles,” he writes, “had no thought of appointing festival days, but of promoting a life of blamelessness and purity;” and he attributes the introduction of the festival of Easter into the church to the perpetuation of an old usage, “just as many other customs have been established” This is doubtless the true statement of the case. The first Christians, being derived from, or intimately connected with, the Jewish Church, naturally continued to observe the Jewish festivals, though in a new spirit, as commemorations of events of which these had been the shadows. The Passover, ennobled by the thought of Christ the true Paschal Lamb, the first-fruits from the dead, continued to be celebrated, and became the Christian Easter. Thus the human instinct which everywhere cries for the commemoration of marked epochs in their national, social, ecclesiastical, or national life, found its legitimate gratification in the public celebration of the events which are the foundation of the Christian faith.

But though the observance of the Paschal festival at a very early period became the rule in the Christian church, a difference as to the time of its observance speedily sprang up between Christians of Jewish and Gentile descent, which led to a long-continued and bitter controversy, and an unhappy severance of Christian union. No rule as to the date of the Easter festivals having been laid down by authority, Christians were left to follow their own instincts. These were naturally different in the Jewish and Gentile churches. The point at issue really was the date of the termination of the Paschal fast. With the Jewish Christians, whose leading thought would be the death of Christ as the true Paschal Lamb, this fast would end at the same time as that of the Jews, on the 14th day of the month, at evening, and the Easter festival would immediately follow, entirely irrespective of the day of the week. With the Gentile Christians, on the other hand, unfettered by Jewish traditions, the first day of the week would be identified with the Resurrection festival, and the preceding Friday would be kept as the commemoration of the Crucifixion, irrespective of the day of the month, the last continuance of the moulding elements in Easter usage. With the one, therefore, the observance of the day of the month, with the other the observance of the day of the week, was the ruling principle. The chief point was the “keeping” or “not keeping” the 14th day of the moon corresponding to that of the month Nisan. Those who, adopting the Jewish rule, did so keep the 14th day were called Τετραώδειοι, Τετράυδειοι, Τετρακάτακτοι, and were stigmatized as heretics. In the absence of any authoritative decision as to the day to be observed and the proper mode of calculating it, other discrepancies arose, which led to controversies and dissensions which, in the words of Ephraem (Pasar, H. E. ixx.), distracted the church, and became a source of mockery and ridicule to the unbelievers. “Some,” he writes, “began the festival before the week, some after the week, some at the beginning, some at the middle, some at the end, thus creating a wonderful and laborious confusion.”

This diversity of usage was gradually brought to an end by the verdict of the Church of Rome. The Roman Christians adopted the ordinary Gentile usage, which, within certain limits, placed the observance of the Crucifixion on a Friday, and that of the Resurrection on the following Sunday. A decree of Pope Pius I., c. 147—the genuineness of which, however, is by no means established—proclaims that “the Pasch should be celebrated on the Lord’s Day by all.” His successor Anacletus was equally firm upon the point. Polycarp, the venerable and sanctified bishop of Smyrna, who, according to Irenæus (apud Euseb., H. E. v. 24), visited Rome in 159 with this object, failed to induce Anacletus to conform to the Quartodecimans usage, which Polycarp had inherited from his master, the Apostle John. Anacletus declined to permit the Jewish custom in the churches under his jurisdiction, but made no scruple of communicating with those who adopted it, and allowed Polycarp to celebrate the Eucharist at Rome. Between thirty and forty years after this visit (197) the same question was controverted in a very different spirit between Victor, bishop of Rome, and Polycrates, bishop of Ephesus, the aged metropolitan of proconsular Asia. This province was the only portion of Christendom that still maintained the Quartodeciman usage, which had been dropped even by the churches of Palestine and Alexandria. Victor's despotism demanded that the Asiatic churches should adopt the Roman system having been met by Polycrates with a courteous but firm refusal, Victor proceeded to excommunicate him and all who held with him. So sweeping a measure shocked the Christian world. Irenæus renounced with the bishop of Rome, and ultimately the Asiatic churches were allowed to retain their usage unmolested. (Euseb., H. E. v. 23-25.) We still find the Quartodecimans usage springing up from time to time in various places, but it never took permanent root, and at the time of the Council of Nicea (325) the Syrians and the Antiochenes were the solitary champions of the Jewish rule. The settlement of this controversy was one among the causes which led the emperor Constantine to summon that council. The consent of the assembled prelates was unanimous. All agreed that Easter should be kept on one and the same day throughout the world, and that none should hereafter follow the blindness of the Jews (Socr., H. E. i. 9). Nothing, however, was said as to the determination of the day. This was practically left to be calculated at Alexandria, the home of astronomical science, by the bishop of that See of the day of the week of the Easter festivals, in the hands of the church under his jurisdiction and to the bishop of Rome, by whom it was to be communicated to the Western churches.
But although measures had thus been apparently taken to secure uniformity of observance, some centuries elapsed before any discrepancy ceased. A more intricate question remained to be solved, viz., how the full moon on which Easter depended was to be predicted. The Nicene decrees had effectively crushed the febrile remnants of the Quartodeciman usage. It was established as a rule that Easter must be kept on a Sunday, but there was no general agreement as to the cycle by which the festival was to be calculated. Some churches adopting one rule, some another. We learn from St. Ambrose (Epist. 23) that in 357 the churches of Gaul kept Easter on March 21, while the churches of Italy postponed it to April 18, and those of Egypt a week later still, to April 25. It appears from an epitaph of Leo the Great (Epist. 64 ad Marcan.) that in 458 there was eight days' difference between the Roman and Alexandrine Easter. Similar discrepancies are mentioned by Gregory of Tours in the year 577, nor did they disappear from the Gallican Church till the 8th century, although by a canon of the Council of Orleans (541) it had been ordained that the Easter festival should be kept at the same time by all, according to the tables of Victorinus. The ancient British Church observed the 84 years' cycle which they had originally received from Rome, and their stubborn refusal to give it up caused much bitter controversy between the Fathers of Iona and the Latin missionaries. These latter universal attempted to fix the stigma of the Quartodeciman heresy on their opponents, and they are sometimes even now spoken of as adopting the Asiatic mode of calculation, and false inferences are thence drawn to the Eastern origin of the British Church. This view is quite erroneous. The early British and Irish Church always commemorated the Crucifixion on a Friday and the Resurrection on a Sunday. The only difference between them and the Roman Church was in the cycle adopted for the computation of the festival, the British Church really adhering to the cycle originally adopted by the Roman Church itself, which had been superseded by the more accurate calculations of Victorinus of Aquitaine (457), and of Dionysius Exiguus (525). This led to a double Easter being observed by the adherents of the two churches. Thus, as we learn from Peires (Ecat. Hist., 257), in 651 Queen Eumanda, adopting the Roman rule, was fasting and keeping Palm Sunday while her husband Oswy, king of Northumbria, was celebrating the Easter festival. This diversity of usage was put an end to in the kingdom of Northumbria by the council of Bernham, or Whitby (664), and the Roman rule was finally established in England by Archbishop Theodore in 669. This rule may be thus briefly stated. Easter day is the first Sunday after the 14th day (not the full moon) of the calendar month which happens on or next after March 21. This calendar month, however, is not the moon of the heavens, nor the mean moon of the astronomers, but an imaginary moon created for ecclesiastical convenience in advance of the real moon (see Prof. De Morgan’s article in Companion to the Almanac, 1848). After nine centuries a fresh discrepancy in the observance of Easter between the Roman and the English Church was caused by the refusal in England to adopt the Gregorian reformation of the calendar, 1582, apparently for no other reason than that the alteration had originated at Rome. Thus difference was happily put an end to in 1752, when the “New Style” was adopted in the United Kingdom. The churches of Russia and Greece, and the Oriental churches generally, still observe the unformed calendar, their Easter falling sometimes before sometimes after that of the Western Church; very rarely, as in 1855, the two coincide. The rules on which the calculation of Easter is based are given in the article Calendar (vol. iv. p. 675).

Easter day, as commemorating the central fact of our religion, has always been regarded as the chief festival of the Christian year, and has been from the earliest times observed with a stately and elaborate ceremonial. It is not, however, the purpose of this article to enter on the ritual observances of Easter, nor on the many curious and interesting popular customs of which the sending of Paschal Eggs, or Easter eggs, is one of the most widely spread with which it is connected in all Christian nations. For these last the reader may consult Brand’s Popular Antiquities, Home’s Every Day Book, and Chambers’s Book of Days.

EASTLAKE, Sir Charles Lock (1793–1865), English painter who became president of the Royal Academy in London, was born on 17th November 1793 in Plymouth, where his father, a man of uncommon gifts but of indolent temperament, was solicitor to the Admiralty and judge ad vocate of the Admiralty Court. Charles was educated (like Sir Joshua Reynolds) at the Plymouth grammar-school, and in London at the Charterhouse. Towards 1809, partly through the influence of his fellow-Devonian Haydon, of whom he became a pupil, he determined to be a painter. He also studied in the Royal Academy school. In 1815 he exhibited in the British Institution his first picture, a work of considerable size, Christ restoring sight to the Daughter of Jairus. In 1814 he was commissioned to copy some of the paintings collected by Napoleon in the Louvre, and he returned to England in 1816, and practised portrait-painting at Plymouth. Here he saw Napoleon a captive on the “Bellerophon,” from a boat he made some sketches of the emperor, and he afterwards painted, from these sketches and from memory, a life-size portrait of him, which was pronounced a good likeness. It belongs to the marquis of Lansdowne. In 1817 Eastlake went to Italy, in 1819 to Greece, in 1820 to Italy, where he remained altogether fourteen years, sojournimg chiefly in Rome and in Ferrara. Subjects of banditti and peasant-life engaged his pencil mostly from 1820 onwards. In 1827 he exhibited at the Royal Academy his picture of the Spartan Isidore—who (as narrated by Plutarch in the life of Agesilaus), rushing naked out of his bath, performed prodigies of valour against the Tholos host. This was the first work that attracted much notice to the name of Eastlake, who in consequence obtained his election as A.R.A., in 1830, when he returned to England, as R.A. In 1850 he succeeded Shakspeare as R.A. (his only worthy competitor being Landseer), with the education of the Prince of Wales besides, to mark the poor estate of British art, or of its official representatives), and, as usual, he was knighted. Prior to this, in 1841, he had been appointed secretary to the Royal Commission for decorating the Houses of Parliament, and he retained this post until the commission was dissolved in 1862. In 1843 he was made keeper of the National Gallery, a post which he resigned in 1847 in consequence of an unfortunate purchase that caused much animadversion, in 1855, director of the same institution, with more extended powers was created. During his directorship he purchased for the gallery 155 pictures, mostly of the Italian schools. He became also a D.C.L. of Oxford, F.R.S., Chevalier of the Legion of Honour, and member of various foreign academies. In 1849 he married Miss Elizabeth Rigby, a lady of some literary distinction. In 1865 he fell ill at Milan; he died at Fiesa on 24th December in the same year, and was buried at Kensal Green. As a painter, Eastlake was gentle, harmonious, delicate, and correct, lacking fire of invention or of execution; eclectic, without being exactly imitative, influenced rather by a love of ideal grace and beauty than by any marked bent of individual power or vigorous originality. Among
E A S — E B E

his principal works (which were not numerous, 51 being
totally exhibited in the Academy) are,—1826, Pilgrima
arriving in sight of Rome (repeated in 1855 and 1866, and
perhaps in the whole chassis-paintings); 1829, Byron's Dream
of the national Gallery, 1834, the Escape of Francesco
di Carrara (a duplicate in the National Gallery), 1841,
Christ lamented over Jerusalem (ditto); 1843, Hagar and
Ismael; 1845, Comus, 1849, Helena, 1851, Ippolito
Torelli; 1853, Violante, 1855, Esdrasil. These female
Venetian glow of tint, are the most satisfactory specimens of
Eastlake's work to an artist's eye. He was an accomplished
and judicious scholar in matters of art, and published, in
1840, a translation of Goethe's Theory of Colours, in 1847
(his chief literary work) Materials for a History of Oil
Painting, especially valuable as regards the Flemish school;
in 1848, Contributions to the Literature of the Fine Arts;
in 1851 and 1855, translated editions of Kugler's History of
the Italian School of Painting, and Handbook of
Painting.

Sir Charles Eastlake was a man of middle height, spare
form, reddish complexion, bright hair (scanty in advanced
life), of unassuming and rather courtier-like bearing;
reluctant to oppose or offend, but with a strong sense of
official duty. He was a neat and appropriate speaker, and
accepted his presidential and other offices with great credit
in the eyes of all who appreciate moderation and cultured
finish in the speech and bearing of a public man.

EASTON, a borough of the United States, and capital
of Northampton county, Pennsylvania, is situated on the
right bank of the Delaware immediately above the
course of the Lehigh, 54 miles north of Philadelphia.
The town is very systematically arranged in spite of the
irregularity of the ground on which it is built; the water
supply from the Lehigh river is abundant, and a strong
pressure is obtained by the elevated position of the
reservoirs. As the centre of a rich agricultural and mineral
district, with free communication both by land and water,
Easton has considerable activity at once in trade and
manufacture. Among its establishments the borough
contains breweries, tanneries, carriage factories, iron
foundries, a rope-walk, and an oil-factory; and South
Easton, on the other side of the Lehigh, has a cotton-
factory, a rolling-mill, and railway engineering works.
The principal buildings are the farmers' and mechanics' institute,
the free reading room, and the Presbyterian or Lafayette
College, which was founded in 1831, and in 1872 had 25
teachers and 359 students. The borough, laid out in
1765, was incorporated in 1789. Population in 1870,
10,887; or, if South Easton be included, 14,154.

EAST SAGINAW, a city of Saginaw county, Michigan,
United States, is situated on the Saginaw river, about 90
miles N.N.W. of Detroit. It extends about three miles
along the river, with a breadth of nearly a mile. It is
the principal depot of the salt and lumber trade of the Saginaw
valley, and possesses foundries, boiler-shops, saw-mills, and
shingle-mills. It is the terminus of the Saginaw Valley
and St. Louis Railway, while a branch of the Flint and Pere
Marquette Railway radiates here to Bay city and another
to Caro, Tuscola county. On the opposite bank of the
river is the Jackson, Lansing, and Saginaw line. East
Saginaw was incorporated as a village in 1853, and obtained

EAU DE COLOGNE, a perfume, so named from the
city of Cologne, where its manufacture was first established
by an Italian, Giovanni Maria Faina, born in 1685, and
by other members of his family, some of whom made it
according to a method due to one Paul Fumus in 1674;
there were in Cologne 33 establishments for the preparation of
the perfume, 28 of which were in the hands of persons
bearing the name of Farina. Eau de Cologne consists of
a solution of various essential oils in strong alcohol. The
purity and thoroughness of the manufacture is of the greatest
importance in the process of manufacture. It was
originally prepared by making a spirituous infusion of
certain flowers, pot-herbs, drugs, and spices, and adding
thereto, after distillation, definite quantities of several
vegetable essences. See Laboulaye, Dictionnaire des Arts et
Manufactures, vol. ii., p. 515. Eau de Cologne consists
of

EBEL, HERMANN WILHELM (1820-1875), a distin-
guished philologist, was born at Berlin, May 10, 1820. He
displayed in his early years a remarkable capacity for the
study of languages, and at the same time a passionate fond-
ness for music and poetry. At the age of sixteen he became
a student at the university of Berlin, applying himself
especially to philology, and attending the lectures of Boeckh.
Music continued to be the favourite occupation of his leisure
hours, and he pursued the study of it under the direction
of Marx. In the spring of 1838 he passed to the university
of Halle, and there began to apply himself to comparative
philology under Pott. Returning in the following year to
his native city, he continued this study as a disciple of
Bopp. He took his degree in 1842, and, after spending
his year of probation at the French Gymnasium of Berlin,
he resumed with great earnestness his language studies.
About 1847 he began to study Old Persian. In 1852 he
accepted a professorship at the Beheim-Schwarzbach
Institution at Flieben, which post he held for six years. It
was during this period that his studies in the Old Slavic and
Celtic languages began. In 1858 he removed to Schnedem-
hul, and there he discharged the duties of first professor
for ten years. He was afterwards called to the chair of
comparative philology at the university of Berlin. The
most important work of Dr Ebel in the field of Celtic
philology is his revised edition of the Grammatica Celtica
of Professor Zeuss, completed in 1871. This had been pre-
ceded by his treatises—De serva Britannicui futuro ac com-
junctione (1866), and De Zevus curii positus in Grammatica
Celtica (1869). He made many learned contributions to
Kuhn's Zeitschrift fur vergleichende Sprachforschung, and
to Schleicher's Beitrage zur vergleichenden Sprachforschung;
and a selection of these contributions was translated into
English by Sullivan, and published under the title of Celtic
Studies (1853). Ebel contributed the Old Irish section to
Schleicher's Indogermanische Chrestomathie (1869). Among
his other works must be named Die Lehworter der Deutschen
Sprache (1856). He died at Misdroy, August 19, 1875.

EBERHARD, SURNAMED BAET (Barbutus), count and
afterwards first duke of Wurttemberg, was born December
2, 1445. He was the second son of Count Ludwig I.,
who died in 1450; and he succeeded his elder brother,
Ludwig II., at the age of twelve (1457). The guardan-
ship of the young count was assumed by his uncle, Count
Ulrich, and he had for tutor the learned John Nauclerus.
Coveting power and careless of learning, he profited little
by the learning of his tutor; and at the age of fourteen he
succeeded in throwing off the restraint of the guardianship,
and assumed the government. But instead of discharging
its duties he thought only of indulging his passions, and
for a time led a wild, reckless life. By some means he
was brought to serious reflections, and we find him, accord-
ing to a custom which had not become wholly extinct,
undertaking in 1458 the pilgrimage to Jerusalem. He also
visited Italy, and made acquaintance with some of the most
famous scholars of the age. His marriage with Barbara,
daughter of Lodovico di Gonzaga, contributed to the amend-
ment and elevation of his character. He began to study
law and to take a practical interest in the promotion of the new
learning, and at the instigation of his wife he founded, in
1477, the university of Tubingen. There he came, in 1481.
the young advocate John Reuchlin, who lectured on Greek at the university and took his degree of doctor of laws. Count Eberhard conceived a great liking for him, appointed him his private secretary, and named him councillor. In the spring of 1482 Eberhard, accompanied by Reuchlin, visited Rome, had an audience of Pope Sixtus IV, and received from him the Golden Rose. On his return he visited Florence, and enjoyed the society of the group of scholars gathered around Lorenzo de' Medici. It was in the same year that Eberhard, by the treaty of Manningen, put an end to the evils which had arisen from a division of the county made in 1437 between his father and his uncle Ulrich, as representatives of the two lines of Urach and Stuttgart, and secured the future indivisibility of Wurttemberg, and the right of primogeniture in his own family. The treaty was made under the guarantee of the empire, and was sanctioned by an assembly of prelates, knights, and landed proprietors. By a limitation of the power of the prince agreed to at the same time, Count Eberhard became the founder of the constitution of Wurttemberg. He made Stuttgart his place of residence, and retained Reuchlin in his service till his own death. Eberhard sympathized with the desire that was daily strengthening for a thorough reformation in the church, and in his own dominions he rendered great services by his regulation of convents. Some of these institutions he secularized. Though a lover of peace, he knew how to bear the sword when war was necessary; and by his courage, wisdom, and fidelity to his engagements he secured the esteem and friendship of the emperors Frederick III and Maximilian I, as well as that of other princes of his time. He was one of the leading members of the Grand Swabian League formed in 1498, and took part in the liberation of Maximilian, then king of the Romans, from his imprisonment at Burgos. In recognition of his great services the emperor at his first diet, held at Worms in 1495, raised Eberhard, without any solicitation on his part, to the dignity of duke, confirming at the same time all the possessions and prerogatives of his house. Duke Eberhard did not live long to enjoy his new dignity. He died at Tubingen on the 25th of February 1496. He had two children by his marriage, but these died in their infancy, and with him the line of Ursch became extinct.

EBERHARD, August Gottlob (1769-1845), a German poet and miscellaneous writer, was born at Belzig, near Wittenberg, in 1769, and died at Dresden on the 15th May 1845. He studied theology at Leipsic; but some stories he contributed to periodicals having proved successful, he devoted himself to literature. Among his earlier works were Ida's Blumenkorbchen (1792), Lust und List, oder was ein Knabe nicht vermag; Ferdinand Werner, der arme Flottenpieler (1802); Pruss Pet Ehr (1804); and Ich hatte Kraft's Lehren und Thaten (1807). For a time he was associated with Becker in the editorship of his Taschenbuch and his Erhellungen, for both of which he wrote numerous tales and sketches. His claim to permanent literary fame, however, depends almost exclusively on his Haunchen und die Kuchles (1823), a charmingly graceful narrative poem in ten parts, which has passed through many editions, and been translated into most of the languages of Europe. An English translation by James Crouchane was published in 1854. In his Der Erste Mensch und die Erde (1828), a poem written in hexameters, the narrative of the creation is given with dignity and spirit. After the death of Vater in 1826, Eberhard succeeded to the editorship of the Jahrbuch der hauslichen Anstalt, a well-known German educational annual. The miscellaneous poems (Vermachte Gedichte) of Eberhard appeared in two volumes in 1833, and his collected works (Gesammelte Schriften) in 20 volumes in 1830-1.
Prussia conferred upon him the honorary title of a privy-counsellor. In 1798 he obtained the degree of doctor in divinity, which was afterwards given him as a reward for his theological writings. He died January 6, 1809.

Eberhard's attainments in philosophy and literature were extensive and profound. He was master of the learned languages, spoke and wrote French with facility and correctness, and understood English, Italian, and Dutch. He had read a great deal, was thoroughly versed in the philosophical sciences, and possessed a just and discriminating taste for the fine arts. He was a great lover of music, and was himself a proficient in the art.

The following is a list of his works—Neue Apologie der Sorenian, &c., 2 vols 8vo, 1772-3, Allgemeine Theorien des Dekans und Magneden, &c., Berlin, 1778, 8vo, an essay which gained the prize assigned by the Royal Society of Berlin for that year, Von dem Begriff der Philosophie und ihren Titeln, Berlin, 1778, 8vo,—a short essay, in which he announced the plan of his lectures on being appointed to the professorship at Halle, Lobreich auf Herrn Johannes Thunmann Prof der Wissenschaft und Berufskraft der Universitat zu Halle, Halle 1779, 8vo, Amatory, eine Geschichte in Dreimal, Berlin, 1782, 8vo,—written with the view of counteracting the influence of those sceptical and Epicurean sentiments in religion and morals which then prevailed in France, and rapidly spreading amongst the higher ranks in Germany. Uber die Macht der Aufklärung in der Philosophie, &c., Halle, 1783, 8vo, Thesen der Wissenschaft und Wissenschaften, &c., Halle, 1783, 8vo, Vermuthete Schriften, Halle, 1784; Neue Versuche in der Philosophie, &c., Halle, 1787, 8vo, 2d ed. with a continuation and chronological tables, 1796; Versuche einer Allgemeinen Deutschen Synonymik, &c., Halle, and Leipzig, 1791-2, 3 vols 8vo, long reckoned the best work on the synonyms of the German language (an abridgment of it was published by the author in one large volume 8vo, Halle, 1790); Handbuch der Ästhetik, &c., Halle, 1790-3, 4 vols 8vo besides the works above mentioned, Eberhard contributed a number of small tracts and essays to various periodical and scientific publications, and translated several foreign works. He was also the editor of the Philosophical Magazine, Halle, 1788-1795, and of the Philosophical Archives, Halle, 1793-1795. These two periodical works, which are now little read, were instituted for the purpose of counteracting the metaphysical principles of Kant, and of vindicating the doctrines of Leibnitz and Wolff. Frederick Nicolas published a memoir on the life and character of Eberhard, Berlin and Stuttgart, 1810, 8vo. See also K. H. Jorden, Lexicon Deutscher Dichter und Prosaisten.

EBERT, FRIEDRICH ADOLF (1791–1834), a very eminent bibliographer, was born at Taucha, near Leipzig, July 9, 1791. He received his early education partly from his father, preacher to the Georgenhaus at Leipzig, and partly at the Nicholas School. At the age of fifteen he was appointed to a subordinate post in the town library of Leipzig, in which his literary tastes, early awakened, were fostered and strengthened. He studied theology for a short time, first at Leipzig and afterwards at Wittenberg, but, by the advice of a friend, renounced it in favour of history. After the close of his academic studies, he made his appearance as an author by the publication in 1811 of a work on public libraries, and in 1813 of another work entitled "Versuche in der Anordnung der lizae literar commode." In the following year he took part in the reorganization of the Leipzig University Library, and in 1814 was appointed secretary to the Royal Public Library of Dresden. The same year he published P. Taubmann's Leben und Verhältnisse, and in 1819 Torquato Tasso, a translation from Guicciardini with annotations. Anxious to turn to good account the rich resources open to him in the Dresden library, he undertook the work on which his reputation chiefly rests, the Allgemeines bibliographische Lexikon, the first volume of which appeared in 1821, and the second in 1820. This was the first work of the kind produced in Germany; but nevertheless it had a higher aim and a more scientific character than its German predecessors. It was called to the post of chief librarian and professor at Leipzig, and at the same time was offered to the duke of Brunswick at Wolfenbuttel. He accepted the latter. But early in 1825 he returned to Dresden as public librarian; he was soon after named private librarian to the king, and in 1834 chief librarian and sub-councillor. Among his other works are—Die Bildung des Bibliothekars (1820), Geschichte und Beschreibung der Koniglichen öffentlichen Bibliothek in Dresden (1822), Zur Handschriftenkunde (1825–27), and Culturperioden des Deutschen Mittelalters (1829). Ebert was a contributor to various journals and encyclopedias, and took part in the editing of Ersch and Gruber's great work. He died at Dresden, November 13, 1834, in consequence of a fall from the ladder in his library a few days before.

EDENGEN, a town of Wurttemberg, in the circle of the Schwarzwald, on the Schluchse, a left-hand tributary of the Danube, 23 miles south of Tubingen and 37 miles west of Ulm. It has rather more than 5000 inhabitants, who are engaged in woolen-weaving, stock-feeding, hat-making, bleaching, and cattle-dealing.

EBIONITES, a Christian sect which was separated from the general Christian church about the end of the 2d century. The origin of the name has been much disputed, some deriving it from Ebion as the founder of the sect, and others from the Hebrew word (EBPW) meaning poor. For the former opinion the authority of Tertullian is quoted, who makes reference to the existence of such a person as Ebion, but as counter-balancing these references there must be considered—1st, that Tertullian being careless and inaccurate, and having no knowledge of Hebrew, may have merely fallen into the error of assuming that the sect took its name from that of a person, 2d, that no mention is made of the existence of such a person either by Ireneus or Origen, and that any reference to a name and later writers are probably borrowed from Tertullian, and 3d, that the name Ebionites had a very general signification, and represented a natural Judaizing tendency which must have had a more comprehensive beginning than that originating in an individual influence. Those who derive the name from the Hebrew word explain it in two ways—as applicable either to the poverty of the doctrines of the Ebionites, or to the poverty of their circumstances. Undoubtedly the name was applied to them with the former significance by their enemies, but it is more probable that they employed it in a holy name already existing, than that they coined it to suit their purpose. That the term was originally applied to the circumstances of the Ebionites seems the only probable supposition; and the argument in support of it may be stated thus:—That the early Christians, both Jewish and heathen, were designated the poor; that the poverty of the Jewish Christians continued to that of the heathen Christians, and Origen states that they in particular were named the poor (EBPW PHUXOTHZNFWY UN TO OXOULOCW TOI XOPAOY TOV XHETOY ANDAOYO), and that, as the Judaizing Christians came gradually to be the only Jewish Christians who required to be distinguished from the heathen Christians, they retained the name. The fathers show a very imperfect knowledge of the origin, history, and doctrines of the Ebionites, but there cannot be any doubt that at first all Judaizing Christians went under that name. In the New Testament there is evidence of the existence of such a party, though it had not then developed into a recognized sect. This apparently did not happen till after the second destruction of Jerusalem and the founding of the heathen colony of Acha Capitolina, when the emperor Hadrian banished from the neighbourhood all Jews who still retained their national peculiarities. As to the particular opinions of the Ebionites we have no authentic statements of the fathers; but at the end of the 2d century, it is evident that the party was still in existence, and thus for the threefold reason—that by the isolation of the Ebionites from the general church the information obtainable regarding them could only be imperfect; that under
the general name Ebionites a good many varieties of opinion are included, and that their opinions varied at different periods of their history. The term Ebionites is used by some writers to include the Nazarenes, who, while recognizing the binding obligation of the Mosaic law on all Jews, did not regard it as binding on heathen Christians (see Nazarenes), but at an early period the stricter Ebionites must have separated themselves from the Nazarenes, who soon became merged in the general church. Of Ebionites proper Origen distinguishes two classes—those who affirm and those who deny the miraculous birth of Jesus and in this he is following the Eusebians. The extreme Ebionites, according to Origen, were only distinguishable from common Jews by the acceptance of the moral teaching of Christ; while those Ebionites who admitted the miraculous birth of Christ did not recognize His divinity proper, but believed that with His human nature the spirit of an angel or archangel, or even of Adam, was incorporated. Both classes of Ebionites seem to have had these points in common—1st, They emphasized the unity of God; 2d, they affirmed the universal obligation of the Mosaic economy; 3d, of the books of the New Testament they received as genuine only the gospel of St. Matthew, 4th, they denounced St. Paul as a separatist, and 5th, they believed that Jerusalem was yet the city of God, and some of them at least believed in Christ's millennial reign. In the time of Eusebius the Ebionites inhabited chiefly the coasts of the Dead Sea, but they dwelt also in Rome and Cyprus. They vanished from history in the end of the 4th or beginning of the 5th century. The ancient authorities on the Ebionites are Irenæus, Hippolytus, Eusebius, Tertullian, Origen, and Theodoret. In modern literature there are—Geiger, in Stand und Lehre der ersten Christenkirche, vol. ii, Leipzig, 1829; Cremer in Winter's Zeitschrift für wissenschaftl. Theologie, 1829; and by Salza, 1839, Bart, De Ebionitarum origine et doctrina ab Ebenezer superbus (Thumner's Untersuchungen v. 1821), Hugentöld, Die Ebioniten konunungen, Jena, 1845, the article "Ebioniten" in Herrgott's Real-Encyclopädie, and Maintz's Geschichte des ersten und zweiten Centurium, London, 1875.

EBOLI, or Evoli, a town of Italy, in the province of Piacentia Citeriore and district of Campagna, situated about thirteen miles from Salerno, on an elevated site commanding a fine prospect over land and sea. It has an ancient castle belonging to the princes of Angris, and its church of St. Francis of Assisi contains a curious picture of the Crucifixion by Roberto di Olcenio. Between the town and Salerno or Sela are the ruins of the ancient Eboli, a place of municipal rank, and the river is still spanned by a bridge of fine Roman construction Population, 8947.

EBONY (Ebros), the wood of various species of trees of the genus Diospyros and natural order Ebenaceae, found in the tropical parts of Asia and America. The best kinds are very heavy, are of a deep black, and consist of heartwood only. On account of its colour, durability, hardness, and susceptibility of polish, ebony is much used for cabinet work and inlaying, and for the manufacture of pianoforte keys, knife-handles, and turned articles. Ceylon ebony is furnished by D. Eburneum, which grows in great abundance throughout the flat country west of Trincomalee. The tree is distinguished from others by the inferior width of its trunk, and its jet-black, charred-looking bark, beneath which the wood is perfectly white until the heart is reached (See Baker, Eight Years' Wanderings in Ceylon, p. 293, 1855). The wood is stated by Sir J. E. Tennent to excel that obtained from D. reticulata of the Mauritius and all other varieties of ebony in the ligneous and intensity of its dark colour. Although the centre of the trees alone is employed, reduced logs 1 to 3 feet in diameter can readily be procured. Much of the East Indian ebony is yielded by the species D. Melanorrh, a large tree 8 to 10 feet in circumference, with irregular rigid branches, oblong or oblong-lanceolate leaves, white flowers, having a 5-cleft calyx; and a round, pulpy berry, containing 2-8 seeds. The bark of the tree is astringent, and mixed with pepper is used in dyeing Saragosse, near Riga, in the wood of D. Eburneum, the species called by the Singhalese Calodosobha, is black, with rich brown stripes, it is not so durable and heavy as the true ebones. That of D. tomentosa, a native of North Bengal, is black, hard, and of great weight. D. montana, another Indian species, produces a dark wood, variegated with white-coloured veins. D. quaranta is the tree from which is obtained the wood known in Ceylon by the name Calamander, derived by Freiham from the Singhalese katam-marude, black-blowing. Its closeness of grain, great hardness, and fine dark-brown colour, mottled and striped with black, render it a valuable material for veneering and furniture-making. Chinese ebones is believed to be the wood of a species of Melo, a genus of Ebenaceae. What is termed Jamaica or West Indian ebony and probably also the green ebony of commerce are produced by Brey Eburna, a ligneous tree or shrub, having a trunk rarely more than 4 inches in diameter, flexible many branches, and orange-yellow, sweet-scented flowers. The wood is greenish-brown in colour, heavier than water, exceedingly hard, and capable of receiving a high polish. From the book of Ezekiel (xxvii. 15) we learn that ebony was among the articles of merchandise brought to Tyre, and Herodotus states (iv. 97) that the Ethiopians every three years sent a tribute of 200 logs of it to Persia. Ebony was known to Virgil as a product of India (Geor., i. 116), and was displayed by Pompey the Great in his Mithridatic triumph at Rome. By the ancients it was esteemed of equal value for durability with the cypress and cedar (see Piny, Nat. Hist, vi. 9, xv. 79). According to Solinus (Polyhistor, cap. iv. p. 363, Paris, 1621), it was employed by the kings of India for sceptres and images, also, on account of its supposed antagonism to poison, for drinking-cups. The hardness and black colour of the wood appear to have given rise to the tradition related by Pausanius, and alluded to by Southey in Thalaba, t. 22, that the ebony tree produced neither leaves nor fruit, and was never seen exposed to the sun. EBRO (in Latin Ibora), the principal river of Spain, rises in the Cantabrian province of Santander, flows in a general south-east direction through Old Castile, Navarre, Aragon, and Catalonia, and falls into the Mediterranean about 80 miles south-west of Barcelona, in 40° 41' N lat. and 0° 30' E long, forming by its delta a very considerable expanse on the otherwise regular outline of the coast. It has a total length of about 340 miles, and its drainage area is calculated at 31,445 square miles. Already a noble stream when it breaks through the pass of Horadada, it becomes navigable about Tudela, but its value as a means of communication is almost neutralized by the obstacles in its channel, and sailing vessels cannot proceed further up than Tortosa. The great Imperial Canal, commenced by the emperor Charles V., proceeds along the right bank of the river from a point about three miles below Tudela, to the monastery of Monte Terero, five miles below Saragossa, and the San Carlos Canal affords direct communication between Amposta at the head of the delta and the harbour of Los Alfajir. The principal tributaries of the Ebro are—from the right hand the Jalon with its affluent the Júcar, the Huerva, the Huerva, the Querol, the Segre, and the Guadalope; from the left the Aragón, the Galligo, and the Segre with its elaborate system of confiding rivers. 
ECARTÉ (French, écarté, separated, discarded), a game at cards, of modern origin, probably first played in the Paris salons, in the first quarter of the 19th century. It is a development of a very old card game called conspectus or French-cuff (Académie des Jeux, various editions; Cotton and Seymour, Compleat Gamester, various editions; and Paul Boitelle d’Ambly, Les Cartes à jouer, Paris, Hachette, 1854).

Écarté is generally played by two persons, but a pool of three may be formed, the player who is out taking the place of the loser, and the winner of two consecutive games winning the pool. At French écarté (but not at English) bystanders who are betting may advise the players, by pointing to the cards they desire them to play, and the loser of the game goes out and one of the remaining takes his place, unless the loser is playing la clochette (i.e., taking all the bets that are offered), when he does not have to resign his seat if he loses.

A pack of cards is used from which the small cards (from the two to the six both inclusive) are removed. The players cut for deal, the highest having the choice. The dealer gives five cards to each player, the deal being made in the following manner, often betraying the nature of the hand.

The dealer then looks at his cards. If satisfied with them he plays, and there is no discarding, if not satisfied he proposes. The dealer may either accept or refuse. If he accepts each player discards face downwards as many cards as he thinks fit, and fresh ones are given from the undealt cards or stock, first to complete the non-dealer’s hand to five, then to complete the dealer’s. Similarly, a second proposal may be made, and so on, until one player is satisfied with his hand. If the dealer refuses the hand is played without discarding.

If the non-dealer announces that he holds the king of trumps, he scores one; and, similarly, if the dealer holds the king of trumps, he scores one.

The non-dealer, being satisfied with his hand, leads a card. The dealer plays a card to it, the two cards thus played forming a trick. The winner of the trick leads to the next, and so on. The highest card of the suit led wins, the cards ranking king (highest), queen, knave, ace, ten, nine, eight, seven. Trumps win all other suits.

The second player to a trick must follow suit if able, and must win the trick if he can, whether by trumping or otherwise.

The scores are for the king (as already explained), and for the majority of tricks. The player who wins three tricks scores one for the point; if he wins all five tricks, he scores two for the sole. If the non-dealer plays without proposing, or the dealer refuses the first proposal, and fails to win three tricks, the adversary scores two, but no more even if he wins the sole. The game is five up.

Hints to Players.—The following hints, which merely touch on the elements of the play, may be of service to beginners:—

Shuffle thoroughly after every deal to prevent the cards packing in suits, otherwise the trump card is not unlikely to be of the same suit as those preceding it, which are in the dealer’s hand. It is an act of courtesy to the adversary to shuffle your own pack well, to save him the trouble of making your cards.

Do not look at your hand when dealer, and look at the dealer’s hand only after you have decided whether he will propose or not. The countenance or manner often betrays the nature of the hand.

Do not announce the king until in the act of playing your first card.

Propose quickly, as hesitation exposes the nature of the hand. Do not be too quick, the hands which should be played without proposing, called jeux de rôles, ought to be thoroughly known.

They are as follows:

1. Hands with three trumps, whatever the other cards.
2. Hands with two trumps which contain—

a. Any three cards of one plain suit.
b. Two cards of one plain suit, one being as high as a queen.
c. Two small cards of one suit, the fifth card being a king of another suit.

4. Hands intermediate between a and e, i.e., with higher cards in one plain suit, and lower in another, e.g., two trumps, knave, ace of one suit, and nine or eight of another; or ace, ten of one suit, and ten of another; or ten, nine of one suit, and knave of another.

5. Three cards of different suits, as high as king, knave, and a small card, or cards of equal value in different suits, as king, ace, ten; or king, and two tens, or two queens; or queen, knave, ace; or three knaves.

6. Hands with one trump, which contain also—

a. King, queen, knave of one suit, and a small card of another.
b. Four cards of one suit headed by king.
c. Three cards of one suit headed by queen, and queen of another suit.

d. Hands with no trump, which contain three queens or cards of equal value in different suits, e.g., four court cards.

7. Hands from which only two cards can be discarded without throwing a king or a trump

Holding cards which make the point certain, propose, as you have the chance of a refusal, and one good card taken in may give you the sole. If you hold a jeu de rôles, and one of the trumps is the king, it is generally right to propose, as your adversary, if he accepts, cannot then take the king. But, except in the case of the king, the value of the trumps does not affect the proposal hands, as the game is not to lead trumps originally (without the king), unless you have three, but to keep them for trumping, and for this purpose high trumps are no better than low ones.

When discarding, throw out all cards except trumps and kings.

If your adversary proposes you should accept, unless you are guarded in three suits (a queen being sufficient guard), in two suits with a trump, or in one suit with two trumps. Hence the rule not to discard two cards, unless holding the king of trumps, applies to the dealer.

The hands with which to refuse are the same as those with which to play without proposing, except as follows:

1. Two trumps and three cards of one plain suit should not be played unless the plain suit is headed by a court card.

2. One trump and a three major is too weak, unless the fifth card is a court card.

3. Hands With three trumps, a guarded card; but

4. One trump and two queens is too weak, unless both queens are guarded.

5. One trump, queen of one suit, and knave guarded of another should not be played unless the queen is also guarded, or the card of the fourth suit is a court card.

6. One trump, a king and a queen, both unguarded, should not be played, unless the fourth suit contains a card as high as an ace.

7. Four court cards without a trump are too weak to play, unless they are of three different suits.

Refuse with three queens, if two are unguarded; otherwise, accept.

Lead from your guarded suit, and lead the highest. An exception to this rule is when two small trumps, a guarded queen, and a small card of another suit, when the single card should be led.

When playing a weak hand after a refusal, with no hope of the point and fear of losing the sole, lead the strongest single card, unless you have a king.

If the strong suit led is not trumped, persevere with it, unless with king of trumps, or queen (king not having been announced), or knave, ace, when lead a trump before continuing your suit. Also, when playing for the sole with a weak trump and high cards, change the suit each time to avoid a ruff. Having made three tricks, then lead the trump.

You should not lead trumps at starting, even if your best suit, unless you hold king, or queen, or knave, or ace, with court cards out of trumps. Holding three trumps, the two best being in sequence, lead a trump.

If cards are refused, it is better to lead from two small cards in sequence, than from a high tenace.

If you have won two trumps, your opponent one, and you hold a trump and a plain card, lead the plain card; but if your adversary has won two trumps and you win the third, lead the trump.

If you make two trumps and have the queen and two small trumps (the king having been announced against you), by leading a small trump you must win the point.

The score has to be considered. If the dealer is at four, and the king is not in your hand, nor turned up, play any cards without proposing which give an even chance of three tricks, e.g., a queen, a guarded knave, and a guarded ten. The same rule applies to the dealer’s refusal, but he ought to be protected in three suits, e.g., three knaves, or a knave and two guarded tens. At the adverse
score of four, and kung not being in hand or turned up, any hand with one trump should be played, unless the plain cards are very small and of different suits. Further, the rule to ask for cards with the point certain does not hold at the adverse score of four, unless kung is in hand or turned up.

If the non-dealer plays without proposing when he is four to the dealer, and the dealer holds the kung, the non-dealer may then play a trump of not marking it. The same rule applies to the non-dealer after a refusal, if the dealer is four to three.

At an adverse score of non-dealer three, dealer four, the dealer should refuse on moderate cards, as the player proposing at this score must have a very bad hand.

At four a forward game should not be played in trumps, as there is no advantage in winning the role.

**Laws of Ecbatá.**—The following laws are abridged from the revised code adopted by the Tartl Club—

**Cutting**—1. A cut must consist of at least two cards. Card exposed in cutting, false cut *Dealing*—2. Order of distribution of cards, whether by three and two, or vice versa, once selected, dealer must not change it during game. If changed, or wrong number of cards dealt, non-dealer, before he looks at his hand, may claim fresh deal. 3. Dealer turning up more than one card, non-dealer, before looking at his hand, may select either for trump, or may claim fresh deal. If he has looked at his hand there must be a fresh deal. 4. Faced card discovered in pack before trump card is turned, fresh deal. 5. Dealer exposing one of his non-dealer's cards, non-dealer, before looking at his hand, has option of fresh deal. 6. Deal out of turn, discovered before trump turned up, void, and dealer must rectify. 7. Modest discovered after trump card turned, and before proposing or playing, non-dealer has option of fresh deal. If deal stands, dealer cannot mark kung card turned, and neither player having superfluous cards discards them. dealer having superfluous cards, non-dealer draws and looks at them, either having too few cards, hand is completed from stock. Either player, before playing with wrong number of cards, adversary has option of fresh deal. 8. Marking kung—9. Kung turned up may be marked any card that is a trump card of new deal turned in kung. In hand it must be announced before playing first card, and if kung is card first led by non-dealer before being played to, or cannot be marked, sl kung in card first played by dealer, it must be announced before he plays again. 10. Player announcing kung when he has not got it, and playing a card without declaring error, adversary may correct score and have hand played over again. If offender was point or role at hand, he scores one less than he wins. Proposing—11. Proposal, acceptance, or refusal made cannot be retracted. Declaring—12. Cards discarded must not be looked at. 13. Either player taking too many cards, and mixing any with his hand, adversary may claim fresh deal. If deal stands, adversary draws superfluous cards, and may look at them if offender has taken any of the cards given. Non-dealer asking for less cards than he discards, dealer counts as tricks all cards that cannot be played to game before dealer, but if he discards from hand, he may complete hand from stock. 14. Dealer giving more or less cards than asked for, non-dealer may claim fresh deal. If deal stands, non-dealer with too many cards discards superfluous ones, and with too few, hand is completed from stock. 15. Faced card in stock after discarding, player may look at it, as it was put into his hand. 16. Cards exposed in giving cards to non-dealer, he has option of taking them or of having next cards, dealer exposing his own cards, no penalty. 17. Dealer turning up top card, after giving cards, cannot refuse second discard. 18. Dealer accepting when too few cards in stock to supply both, non-dealer may take cards, and dealer must play his hand. Playing—19. Card led in turn cannot be taken up again. Card played to a lead can only be taken up prior to another led, to save revoke or to correct error of not winning trick. Card led out of turn may be taken up prior to its being played to 20. Player naming one suit and leading another, adversary has option of requiring suit named to be led. If offender has none, no penalty. 21. Player abandoning hand, adversary is deemed to win remaining tricks, and scores accordingly. Secretary, and not winning trick—22. For either of these offences same penalty as in law 10. Incorrect packs,—23. Deal in which discovery made, void, preceding deals good. By-passers—24. If players declare to play English skirts, bystanders, having more, not allowed to make remarks or give advice, unless bystanders play out game of player resigning, if bystanders make remark which affects score, player prejudiced may call on him to pay his stock, which bystanders make, bystanders may correct score, give advice (by pointing only), or play game of player who resigns.

**Ecbatanata (Greek, Eékbatáneía), or, as it is found in Ezechiel, Aýbóvneía, a name applied by the classical writers to several and possibly to no fewer than seven distinct sites,—the capital of Media Atropatene, the capital of Media Magna, the citadel of Persepolis, a Syran city on Mount Carmel, the Assyrian castle of Amadiyah, the Aramean stronghold of Europa, and the city of Iphathah.** This diversity of application doubtless arises from the fact that the word was a descriptive epithet, but its derivation has not been ascertained, and it is even possible that under the Greek guise we may have two totally distinct originals. According to the usual hypothesis the meaning is treasury or place of assemblage, from the Old Persian magdan. The Median use of the name is the only one of special moment, involving, as it does, a difficult question of identification. It has long been admitted on all hands that the modern Hamadan, a town of Persia at the foot of the Elwond Mountains, occupies the site and preserves the name of the great city of Ecbatanata, which was the summer residence of the Persian kings from the time of Darius Hystaspes to the Greek conquest, and afterwards became the capital of the Parthian empire. But the further identification of this Ecbatanata with the Ecbatanata of Herodotus, still maintained by some authorities, has been disputed by Sir Henry Rawlinson, who locates the latter city at Takht-i-Suleiman, a conical hill about halfway between Hamadan and Tiberias, which agrees in its main topographical features with the Herodotean description, and is still covered with extensive ruins of ancient date. There it was at least possible for the Median monarch Dares to surround his palace with seven concentric walls of different colours, raising one behind the other, but, if the site of Hamadan be adopted, this part of the account, recently shown by the similar arrangement at Borappa to be so probable in itself, must be relegated to the region of myths. One or other of the cities is possibly mentioned in the Old Testament as Achamutha or Amatha, in the Apocalypse the name frequently occurs in the form of Ekkatanata.

**Eccard, Johannes (1553-1611)**, a celebrated composer of church music, was born at Mindenhausen on the Unstrut, Prussia, in 1553. After having received his first musical instruction at home, he went, at the age of eighteen, to Munich, where he became the pupil of Orlando Lasso, one of the greatest masters of the France-Belgian school, and his company Ecard had to leave. He first made his name in 1574 we find him again at Minden, where he resided for four years, and edited, together with Johann von Bork, his first master, a collection of sacred songs, called *Crepundia sive a Helmsbi.* Soon afterwards he obtained an artistic appointment in the house of Jacob Fugger, the great Augsburg banker, and in 1583 he became assistant conductor, and twelve years later first chancel-master, at Konigsberg in Prussia. In 1608 he received a call to Berlin as chief conductor of the elector's church, but this post he held only for three years, owing to his premature death in 1611. Eccard's works consist exclusively of vocal compositions, such as songs, sacred cantatas, and chorales for four or five, and sometimes for seven, eight, or even nine voices. Their polyphonic structure is a marvel of art, yet excites the admiration of musicians. At the same time his works are instinct with a spirit of true religious feeling. They have indeed a religious and historic significance beyond their artistic value. The important position of music in the service of the Reformed churches is well known. It was derived from the foregoing appeal again to, the feelings of the people. Luther himself recognized the elevating influence of the art by
E C C — E C C

cultivating it with zeal and success. His setting of the beautiful words "Euu festa est uxor amabilis" is still regarded by the Germans as their representative hymn. Eccard and his school are inseparably connected with the history of the Reformation.

Of Eccard's songs a great many collections are extant; for an enumeration of the old and rare editions the reader is referred to the works of Winterfeldt, who has devoted great care to the study of Eccard, and by Doring (Choral-klan, p. 47).

ECCELINO, or Ezcelino da Romano (1194-1259), fourth of the name, a famous Ghibelline chief, was born April 25, 1194. The family traced its origin to Eccelin, a knight who about 1088 followed the emperor Conrad II. into Italy, and received from him among other fiefs that of Romano, in the neighbourhood of Padua. Eccelino IV. was the elder of the two sons of Eccelino III., surnamed the Monk, who divided his little principality between them in 1223, and died in 1235. In his youth Eccelino displayed the dauntless courage and the power of dissimulation which characterized him through life. In 1226, at the head of a party of Ghibellines, he got possession of Verona, and was appointed podestat. He became one of the most faithful servants of the great emperor Frederick II., who by a charter granted in 1232, confirmed him in his possessions.

Four years later (1236) he invited Frederick to enter Italy to his assistance, and in August met him at Trent. Eccelino was soon after besieged in Verona by the Guelphs, and the siege was raised by the emperor. Vicenza was next stormed, and the government was given to Eccelino. But he was excommunicated by the Congregation of the Propaganda.

In 1237 the latter marched against Padua, became master of the city by capitulation, and crushed the party of Ghilbellines, whose surname is derived from Eckel, or Eccel, a name of German origin. Eccelino was soon after appointed to his own. He had cultivated philosophy, became professor of Arabic and Syriac in the college of the Propagandists. Called to Paris in 1630 to assist Le Jay in the preparation of his polyglott bible, he contributed to that work the Arabic and Latin versions of the book of Ruth and the Arabic version of the third book of Maccabees. A quarrel with Gabriel Sionita, one of his condutors, whose work he had revised, led to a sharp controversy in which De Flavigny took part. He returned to Rome in 1642, but resumed his residence in Paris in 1645. Being invited by the Congregation of the Propaganda to take part in the preparation of an Arabic version of the Scriptures (1652), he went again to Rome in 1652 or 1653 to Rome, where he died in 1664.

Eccelens is the elder of the two sons of Eccelino II., surnamed Romano, who about 1223, and died in 1235. In his youth Eccelino displayed the book of Ruth and the

ECCHELLENSIS, or Ecclehens, Abraham, a learned Maronite, whose surname is derived from Eckel in Syria, where he was born towards the close of the 16th century. He was educated at the Maronite college in Rome, and, after taking his doctor's degree in theology and philosophy, became professor of Arabic and Syriac in the college of the Propagandists. Called to Paris in 1630 to assist Le Jay in the preparation of his polyglott bible, he contributed to that work the Arabic and Latin versions of the book of Ruth and the Arabic version of the third book of Maccabees. A quarrel with Gabriel Sionita, one of his condutors, whose work he had revised, led to a sharp controversy in which De Flavigny took part. He returned to Rome in 1642, but resumed his residence in Paris in 1645. Being invited by the Congregation of the Propaganda to take part in the preparation of an Arabic version of the Scriptures (1652), he went again to Rome in 1652 or 1653 to Rome, where he died in 1664.

Eccelens published several Latin translations of Arabic works, of which the most important was the Chronicon Orientale of Ibu-ar Râhîm (Paris, 1653). He was engaged in an interesting controversy with Selden as to the historical grounds of episcopacy, in the course of which he published his Chronicon Ecclesiæ ad Seldams Originum (Rome, 1661). Conjointly with Borelli he wrote a Latin translation of the 5th, 6th, and 7th books of the Conics of Apollonius of Perga (1661).

ECCLES, a populous village of England, in the county of Lancaster, four miles west of Manchester by railway, and practically an outlying suburb of that city. The parish church of St Mary, an ancient structure, was enlarged and extensively repaired in 1863-4; and several dissenting places of worship have been built in the present century. The cotton-manufacture is extensively carried on in the immediate neighbourhood. Previous to the Reformation all the monks of Whalley Abbey had a grange at what is still called Monks' Hall; and in 1864 many thousands of silver pennies of Henry III. and John of England and William I. of Scotland were discovered near the spot. Ainsworth, the author of the Latine and English dictionary so long familiar to English students, was born at Eccles in 1660; and it was at the vicarage of the Right Hon. William Huskisson expired on 15th September 1830 from injuries received at the opening of the Liverpool and Manchester Railway.

ECCLESLIA, in Grecian antiquity, the general assembly of Athenian citizens, who met from time to time to discuss public affairs. The first of these were held, according to the laws of Solon, four times in each prytany, or period of thirty-five days; while the others were only summoned on some pressing emergency. When any measure of unusual importance was to be publicly debated, the people were summoned from the country by special messengers. An assembly thus convened was called a cataclena. Much discussion has taken place as to the exact days of the month on which the ecclesiae were held; but the result has only been to prove either that there were no days invariably fixed for them, or that no day was employed by which to determine accurately what these days were. In Ulpian it is stated that when there were three assemblies a-month, the first fell on the eleventh, the second on the twentieth, and
the third about the thirtieth of the month. The likelihood is that they were held at regular intervals though the days were not absolutely fixed. Ecclesiæ were originally held in the Agora or Forum. The place of meeting was subsequently removed to the Pnyx, and afterwards to such of the greater temples as might be most convenient. The Pnyx was by the west of the Areopagus, and commanded an extensive view. It was partly within the city walls, and had an area of about 13,000 square yards. On its northern side, cut out of the solid rock, was the bema or hustings from which the speakers addressed the people. From this tribunal a splendid view of the principal buildings of the city might be had. The right of assembling the people lay with the prytanes, or presidents of the senate or Council of Five Hundred, who both advertised beforehand the business to be discussed, and on the day of meeting sent round a crier to remind the citizens that their presence was required. In times of war, however, or other national crises, the generals of the army sometimes assumed this privilege, though it was necessary for them in doing so to give notice of their intention by a public proclamation. They also sometimes claimed the right of preventing the ecclesia from assembling; but their claims to this privilege were not generally recognized. Such of the citizens as refused to attend were fined, and six magistrates called lexarchs were appointed to collect the fines. To assure a full meeting, the custom was ultimately introduced of paying the poorer classes a small sum for their attendance. This sum was originally an obolus, but after the time of Pericles it was raised to three. According to the usual order the proceedings of an ecclesia were commenced by a recitation or ceremonial purification of the place of assembly. The victims sacrificed were usually sucking pugs, whose blood was sprinkled round the boundary of the assembly. The crier next offered up a prayer to the gods for guidance, after which the business for which the assembly had been convened was introduced. According to the laws of Solon, the crier first called upon citizens above fifty years of age to speak and then upon all others, but this distinction was afterwards abolished, and the discussion was open from the commencement to all citizens of whatever age. The vote was generally taken by show of hands. In certain special cases, however, such as those affecting individual rights, the balloting was used. The decision to which the assembly came was called a paeplokuma. The ecclesia was sometimes adjourned from one day to the next, and it generally broke up at once if any of those present declared that he had seen an unapproachable one or if anything like excitement occurred. The word ecclesia came to mean any assembly regularly convened, and in New Testament Greek it is used to denote the assembly of Christians in any particular place, or the Christian church.

ECCLESIAS. The Book of, or, has been handed down by Hebrew tradition as one of the three canonical books of Solomon, son of David, the other two being Proverbs and the Song of Songs, or Canticles.

Two different practices have obtained from time immemorial as to the position of this book in the Bible. According to one, which is preserved in the MSS. and editions of the Septuagint, and is followed by the MSS. and editions of the Vulgate, Ecclesiastes is the second in the order of the five books which, according to the Alexandrian Jews and the Greek and Latin churches, was written by Solomon. The order of these five books in the Alexandrian and Sinaitic Codices and in the MS. Bible of Charles the Bold, circa 850 (British Museum) is Proverbs, Ecclesiastes, Canticles, Wisdom, and Ecclesiastes. According to the other practice the book in question is separated from those which are supposed to belong to the same author, and

3. Ecclesiasticus is generally referred to the other four Megilloth.

Thus in the oldest dated MS. of the entire Hebrew Bible yet known (1009), now in the imperial library of St. Petersburg, it is the third of the five Megilloth, viz., Ruth, Canticles, Ecclesiastes, Lamentations, and Esther. Though this order is also to be found in the Spanish and Italian MSS., it is by no means universal. Additional MS. 15,350 of the British Museum not only puts Ecclesiastes before Canticles, but places Ruth before the Psalms. In the fourteen pre-Reformation German translations of the Bible (1462-1518), and in Wycliffe's English version, where the five Solomonic books are still kept together, the order of the Septuagint and Vulgate is followed, as is also the case in the English Catholic version (Donah, 1610). Luther, who was the first to remove Wisdom and Ecclesiasticus from this group, and place them with the other so-called Apocryphal books at the end of the Old Testament, has left Ecclesiastes as second in the order of the Solomonic writings. In our first English translation of the entire Bible (1535) Coverdale followed the example of the great Continental Reformer. Hence this narrower group and this position of Ecclesiastes in the succeeding English Bibles, and in the present Authorized Version.

There is hardly another book in the Bible which has called forth so many commentaries and suffered as much at the hands of expositors as Ecclesiastes. Nearly 350 years ago Luther remarked,—"Difficult as this book is, it is almost more difficult to clear the author of the visionary fancies palpied upon him by his numerous commentators than to develop his meaning." What would this sagacious Reformer have said if he could have seen the countless speculations of which it has been the subject since his days? We are positively assured that the book contains the holy incantations of Solomon, together with a prophetic vision of the splitting up of the royal house of David, the destruction of the Temple, and the Captivity, and are equally assured that it is a discussion between a refined sensualist and a sober sage Solomon publishes in it his repentance, to glorify God and to strengthen his brethren, he wrote it "when he was inquired and scolded during his amours and idolatry." "The Messiah, the true Solomon, who was known by the title of son of David, addresses this book to the saints," a prodigate who wanted to disseminate his infamous sentiments palpied upon Solomon. It teaches to despise the world with all its pleasures, and flee to monasteries, it shows that sensual gratifications are men's greatest blessing upon earth. It is a philosophic lecture delivered to a literary society upon topics of the greatest importance, it is a medley of heterogenous fragments belonging to various authors and different ages. It describes the beautiful order of God's moral government, showing that all things work together for good to them that love the Lord, it proves that all is disorder and confusion, and that the world is the sport of chance. It is a treatise on the sumum bonum, it is "a chronicle of the lives of the kings of the house of David from Solomon down to Zedekiah." Its object is to prove the immortality of the soul, its design is to deny a future existence. Its aim is to comfort the unhappy Jews in their misfortunes; and its sole purport is to pour forth the gloomy imaginations of a melancholy misanthrope. It is intended "to open Nathan's speech (1 Chron. xvii.) touching the eternal throne of David," and it propounds by anticipation the modern discoveries of anatomy and the Harveyan theory of the circulation of the blood. "It foretells what will become of man or angels to eternity;" and, according to one of the latest and greatest authorities, it is a keen satire on Herod, written 8 B.C., when the king cast his son Alexander into prison.1

1 For an historical account of the interpretation of Ecclesiastes, with detached specimens of these "interpretations," see Gustav, "Commentary on Ecclesiastes," pp. 27-32, London, 1861.
One of the causes which have contributed to obscure the design of this book is the name Ecclesiastes. This title, which derives from Solomon, is an echo to theOld Testament, has been given by it to the Septuagint and Vulgate in accordance with a Jewish tradition, and has been adopted alike by the pre- and post-Reformation authorized versions of the Scriptures. The Jewish tradition in question is to be found in the Midrash Rabba on Eccles. i. 1, where we are told that "Solomon was called Coheleth = Ecclesiastes, because his discourses were delivered in the Cahal = Ecclesia." Hence the title in the Alexandrian version, which was followed by the Latin Authorized Version, and is reproduced by Wycliffe's Bible "the boe of Ecclesiastes, that is to say, boe of talker to the people." Hence, too, Luther's title Prediger, which is followed in our first printed English Bible "the boke of the Preacher, otherwise called Ecclesiastes" (Coverdale, 1535), and which is perpetuated in our Authorized Version. This title, however, is contrary to the grammatical form of the word Coheleth, as well as to the usage of the root of which it is derived. It has arisen from a desire on the part of the Jewish synagoge to exhibit Solomon in the garb of a penitent confessing his sins, and, by detailing his bitter experience, warning the people publicly to avoid the thorny path he has pursued and walk in the ways of righteousness. Lastly, the desire is to perpetuate the historical-sacred import of the book, and is contradicted by the signification of the name.

Coheleth is the participle feminine Kal of kāhāl, which primarily means to call, to call together, to collect, to assemble. The verb occurs about forty times in the Hebrew Bible, and is invariably used for assembling or gathering people together, especially for religious worship. Hence the name means a collection, or an assemblage of people into the presence of God, a female gatherer or an assembly to God. This meaning of the name is fully confirmed by another Jewish tradition, which is embodied in the Midrash Yalkut (Eccles. i. 1), and is exhibited in the ancient Greek versions of Aquila and Symmachus. Chapter 1. 12 tells us that Solomon is meant by this designation, since he was the only son of David, who was king over Israel in Jerusalem. The feminine and symbolic allusion arises from the fact that in chapter v. 27 of this very book Solomon is described as personified Wisdom, which appears in Eccl. iv. 10, vili. 1, &c., as Coheleth, or the female gatherer of the people. This symbolic name is, moreover, intended to indicate the design of the book itself, and to connect Solomon's endeavours here with his work recorded in i. Kings viii. Solomon, who in i. Kings vii. is described as gathering (kōpher) the people to hold communion with the Most High in the place which he erected for this purpose, is here again represented as the gatherer (rēvar) of the far-off people of God. As he retains his individuality, he sometimes describes his own experience, and sometimes utters the words of Wisdom, whose organ he is.

The design of this book, as indicated in the symbolic title of its hero, is to gather God's people, who were led astray by the inexplicable difficulties in the moral government of the world, into the community of God. Coheleth shows them the utter insufficiency of all human efforts to obtain real happiness—that it cannot be secured by wisdom, pleasure, industry, wealth, and prudence, but that it consists in the calm enjoyment of our lot, in resignation to the dealings of Providence, in the service of the Most High, and in looking forward to a future state of retribution, when all the present mysteries shall be solved, and when the Righteous Judge shall render to every man according to his deeds, whether they be good or evil.

Instead of writing an elaborate metaphysical disquisition to refute the various systems of happiness which the different orders of mind and the different temperaments had constructed for themselves, Coheleth introduces as narrating his painful experience in all his attempts. He shows how he had vainly striven to divert the longings of his soul by various experiments, and the only solution which can pacify the perplexed mind when contemplating the unhonourable dealings in the moral government of the world.

The theme or problem of the book is given in chapter i. 2–11. On the assumption that there is no hereafter, and that the longing soul is to be satisfied with the things here, Coheleth declares all human efforts to satisfy the longings of the soul to be utterly vain (chap. i. 2), since conscious man is more deplorable than unconscious nature, for he must speedily quit this life, whilst the earth abides for ever (4); the objects of nature depart and retrace their course again, but man disappears and is for ever gone (5–11).

In corroboration of the allegation in the prologue, and to show the utter failure to satisfy the cravings of the soul with mere temporal pleasures, Coheleth tells us that, with all the resources of a great monarch at his command (chap. i. 12), he applied himself assiduously to discover by the aid of wisdom the nature of earthly pursuits, and found that they were fruitless (13–14), since they could not alter destinies. Hence, when he reflected upon the large amount of wisdom which he had acquired, he came to the conclusion that it is utterly useless (16–17), for the accumulation of it only increased his sorrow and pain (18). Wisdom having failed, Coheleth resolved to try pleasure, to see whether it would yield the desired happiness, but he soon found that this too was vain (chap. ii. 1), and hence denounced it (2). After procuring every imaginable pleasure (3–10) he found that it was utterly insufficient to impart lasting good (11). He then compared wisdom with pleasure, the two experiments he had made (12); and though he saw that the former had a decided advantage over the latter (13, 14a), still he also saw that it does not except its possessor from death and oblivion, but that the wise man and the fool must both die alike and be forgotten (14b–16). This melancholy thought made him hate both life and the wealth which he had acquired by wisdom and industry, and, which, to aggravate matters, he perceived might lead to a reckless folly (17–21). It convinced him that man has nothing from his toil but wearisome days and sleepless nights (22, 23), and that there is therefore nothing better for man than to enjoy himself (24a). Soon, however, he found that this too is not in the power of man (24b, 25). God gives this power to the righteous and withholds it from the wicked, and it is after all only transitory (25).

Having shown the failure of wisdom, knowledge, and enjoyment to calm the distracted mind which broods over the problem that, whilst the objects of nature depart and retrace their steps, again man vanishes and is for ever forgotten, Coheleth now shows the vain efforts of industry to satisfy the restless longings of the soul. All the events of life are immutably fixed (chap. iii. 1–8); labour is therefore fruitless (9). Even the regulations to human labour which God has prescribed in harmony with this fixed order of things man in his ignorance often mistakes (10, 11). Nothing is therefore left but the enjoyments as one finds them. But this, too, as has already been shown, is a gift of God (12, 13), who has fixed everything to make man feel his utter dependence on and fear the Lord (14, 15).

The success of the wicked does not militate against this conclusion, for there is no right order of things (16, 17). But even if all terminates here, and man and beast have the same destiny (17–21), this only shows all the more that the enjoyment of life is our only portion
The wisest and most painstaking Coheleth found by experience that all human efforts to obtain real happiness are vanity of vanities (xii, 8-10), that the sacred writings alone contain the clue to it (11, 12), that there is a Righteous Judge who takes cognizance of all we do, that He will in the great Day of Judgment try the conduct of us all, and that we are therefore to fear Him and keep His commandments (13, 14).

From this analysis of its contents it will be seen that the book consists of four parts, with a prologue and epilogue. The prologue and epilogue are distinguished by respectively beginning with the same phrase (i, 1, 8) and ending with two marked sentences (i, 11, xii 14). The prologue, which consists of chapter i. 1-11, propounds the grand problem of the book, whilst the epilogue, which consists of chapter xii. 8-12, gives the solution proposed by Coheleth. The four sections, which are respectively indicated by the recurrence of the same formula or refrain, viz., ii. 26, v. 19, and xiv. 15, give the result of each experiment or group of efforts to satisfy the cravings of the longing soul, apart from the conclusion at which Coheleth arrived.

Coheleth fills up a gap in the Old Testament lessons throughout the Hebrew Scriptures virtue and vice are spoken of as being visibly rewarded on earth. God declares at the very opening of the law that He will show mercy to thousands of those who love Him and keep His commandments, and visit the misfortune of those who hate Him to the third and fourth generation (Exod. x. 5, 6).

The whole of Lev. xxvi. and of Deut. xxviii. are replete with promises of earthly blessings to those who will walk in the way of the Lord, and threatenings of temporal afflictions upon those who shall transgress His law. The faithful fulfillment of these promises and threatenings in the early stages of the Jewish history confirmed every Israelite that "God judgeth the righteous, and God is angry with the wicked every day," and afforded a source of consolation to which the righteous resorted when the power of the wicked threatened destruction (1 Sam. xiv. 13-16, xxi. 23, Ps. vii. ix, ixi) Like a net of thin threads is this doctrine spread over the entire Old Testament (comp. Ps. xvii. 1, 2, xxvi. 1-2, xxvii. 1-3, xxxv. 7-9, Is. 20-24, Jer. 24; Ezek. xxxv. 2-3, xxxvii. 1-3, xxxvii. 1-3, Ezek. ix. 7-9, Jer. 8-17, Malachi ii. 17). By limiting this bar of judgment to this side of the grave, the Old Testament yielded no explanation of, or succour under, the great night of the righteous suffering all their life, and then dying for their righteousness, and of the wicked prospering and prolonging their days through their wickedness. It was under such despairing circumstances that Psalms xxxvii. xix. and lixiv. were written. But these very Psalms endeavour to allay the prevailing scepticism in the moral government of God, by declaring that the righteous shall ultimately prosper and prolong their days upon the earth, and that the wicked shall suddenly be cut off in great misery. Hence the recurrence of this perplexity passing over into despair when these reassurances and consolations were not realized by experience, and when the sufferers, however conscious of their innocence, were looked upon as rejected of God in consequence of some secret sin. The book of Job, which so successfully combats the latter notion by showing that afflictions are not always a proper test of sin committed, only confirms the old opinion that the righteous are visibly rewarded here, inasmuch as it represents their calamities as transitory, and Job himself as restored to double his original wealth and happiness in this life.

Under the Persian and Ptolemaean dominion over Palestine, the political affairs of the Jews were such as to render the incongruity between the destinies of men and
their morals still more striking. Hence people began to
arrange the character of God.

“Every one that doeth evil
Is good in the sight of Jehovah, he delighteth in them,
Or where is the God of justice?”—Eccl. 7. 17.

“...it is vain to serve God,
And what profit is it that we keep his ordinances
And be thankful before Jehovah of Hosts?
For now we pronounce the proud happy;
They that work wickedness are built up;
They that tempt God are delivered.”—Mal. ii. 17, 18.

Under these circumstances, when the inheritance of the
Lord, which was to be the praise and the ruler of all the
earth, was reduced and degraded to the rank of a mere
province; when her inhabitants were groaning under the
extortions and tyranny of hirelings; when her seats of
justice were filled by the most vassal and corrupt men
(Ecc. v. 16); when might became right, and the
impunity and success with which wickedness was practised
swelled most alarmingly the ranks of the wicked
(viii. 10, 11); when the cherished faith in temporal retribution
was utterly subverted by the melancholy experience of the
reversion of destinies; when the longing minds of the
desperate people, released from the terrors of the law,
began to import as well as to construct philosophic systems
to satisfy their cravings (xiv. 12), and to resort to various
other experiments to obtain happiness, Coheleth disclosed
a new bar of judgment in the world to come. There
the Judge of the quick and the dead will rectify all the
inequities which take place here.

On the Continent, where Biblical criticism has been cul-
tivated to the highest degree, and where Old Testament
exegesis has become an exact science, the attempt to prove
that Solomon is not the author of Ecclesiastes would be
viewed in the same light as adding facts to demonstrate
that the earth does not stand still. In England, however,
some scholars of acknowledged repute still adhere to the
Solomonic authorship. Their principal argument is that
the unanimous voice of tradition declares it to be so. We
at once concede the fact. The Jewish synagogues univer-
sally believed that Solomon wrote Canticles while young,
Proverbs when in middle life, and Ecclesiastes in his old
age (Midrash TaHkut, Eccl. i. 1), and the Christian church
has simply espoused the Jewish tradition. But with all
due deference, we submit that tradition has no authority
whatever to determine points of criticism. It is an
acknowledged fact that the ancient Jews and Christians, and
indeed the leaders of thought to the
beginning of the 16th century, had not the slightest
appreciation of peculiarities of style. The different shades
of meaning in which the same expression is used by
different authors, the variations in forms, phrases,
constructions, and sentences which obtained at diverse periods,
and which supply definite data to philologasts, and have
been reduced to a science in modern days, began only to
be noticed at the time of the Reformation, when the vital
power of criticism was first applied to traditional dogmas.
The spell of tradition once broken, thinking men soon
began to recognize the literary style and the respective
artistic merits of the component parts of the Bible. Hence
Luther already declared, “Solomon did not write the book
of Ecclesiastes; it was compiled by Sirach, at the time of the
Macabeans. . . . It is, like the Talmud, made up of many
books, which perhaps belonged to the library of
King Ptolemy Eupator in Egypt.”

No impartial student, with even a moderate knowledge of the genius of the
Hebrew language, can fail to see the striking difference
in the style of the pre- and post-exile books of the Old Testa-
ment. In the case of Ecclesiastes the difference is still
more unmistakable. Of the vocabulary and phrases in
Ecclesiastes a part is to be found in the post-Babylonian
biblical writings, and that only in the Chaldean portions;
whilst another part has no parallel in the Bible, but is only
to be met with in the Mishna, the Talmud, and other post
biblical productions. Unless, therefore, it is maintained
that the Hebrew of the Bible, which extends over a period
of several thousand years, and purports to exhibit the styles
of a number of writers who lived in different districts, is
unlike any other known literary language, that it had no
development and no epochs in its literature, the striking
Rabbinic complexity of Ecclesiastes must assuredly stum
at the latest composition in the Old Testament. Those
who know the vast orthodoxy of the eminent Hebrew
scholar, Professor Delitzsch, will feel theconvincing power
of this fact when they find that he assigns to Ecclesiastes
the latest date of any book in the Hebrew Bible, because
it is written in this unquestionably late language.

We have abstained from adducing any other arguments derived
from its contents, because this appears superfluous. An
intelligent reader even in the English translation can see
that the representation of Coheleth as indulging in sensual
enjoyments and acquiring riches and fame in order to
determin what is good for the children of men (chap.
8, 9); and the leaders of thought to the
development and no epochs in
biblical writings, and that only in the Chaldee
period of the
book, that the complaint about the multiplication
of profane literature (chap. xii. 12) could only have been
made at a time when the Jews became acquainted with the
Greek writings and Alexandrian philosophy. The book,
however, is of Palestinian origin, as is evident from the
frequent allusion to rain (vii. 12–20), which does not fall
in Egypt; the reference to the Temple and its worship
(v. 7); and the mention of “the city” (vii. 10), though,
from the remark הַשֵּׁבָּה in the city (v. 7), it would
seem that the writer did not live in Jerusalem itself but in
the neighbourhood.

From the records we possess of the discussions on the
Hebrew canon we see that at the synod at Jerusalem, circa
65 A.D., and at a subsequent synod in Yabne, circa 90
A.D., the question was still an open one whether Ecclesiastes
was canonical. The school of Shammait then deemed
against its canonicity, whilst the school of Hillel passed it
as canonical (Mishena Yadaot, iii. 5, iv. 6; Edershein,
39). The reasons assigned for its rejection from the
Talmud, are that chap. ii. 5, iii. 5, and vili. 5 contradict
each other, and that the book does not exhibit any signs
of its being inspired (Sabbath 30 b, Megillah 7 a).
According to the Midrash Rabba on Eccl. xi. 9, the advice
to enjoy sensual pleasures was considered as contradicting
of Moses (comp. Eccl. xi. 9 with Numb. xv. 39) and
inclining to heresy. The admonition, however, to fear God
and the doctrine of a future judgment were urged in its
favour and ultimately prevailed. The sages showed that
the contradictions were apparent only, and the book was
declared canonical.—(Both of St. Nathan, cap. i.) Hence it
passed over into the Christian church as part of the canon.

Literature.—The most important commentaries on Ecclesiastes
which furnish the best materials for forming an independent opinion
on this strangely difficult book are—Knobel, Commentarius über das Buch
Koheleth, Leipzig, 1836; Ewald, Kohelet, in Das kleine, Aller
Bunde., 2d ed. vol. u. 267, kct., Gottingen, 1807; Hitzig, Der
Prophet Solomon im Kulturzustande jehovitischer Handbuch zum alten
Testament, vol. iv., Leipzig, 1877; and the Commentary
Ecclesiastes, New York, 1851. Elster, Commentarius über den Prediger,
Göttingen, 1855; Graetz, Koheleth, Leipzig, 1871; Delitzsch,
Habakkuk und Koheleth, Leipzig, 1873. The latest two
volumes are the post-Sinaitic edition of the book. For
the history of the interpretation see Ginsburg, Coheleth, commonly called the
Book of Ecclesiastes, London, 1861. (C. D. G.)
ECLESIASTICAL COMMISSION. This is a standing commission invested with very important powers, under the operation of which extensive changes have been made in the distribution of the revenues of the Church of England. It was one of the results of the vigorous movements for the reform of public institutions which followed the Reform Act of 1832. In 1833 two commissions were appointed "to consider the state of the several dioceses of England and Wales, with reference to the amount of their revenues and the more equal distribution of episcopal duties, and the prevention of the necessity of attaching by commendam to bishoprics certain benefits with cure of souls; and to consider also the state of the several cathedral and collegiate churches in England and Wales, with a view to the suggestion of such measures as might render them conducive to the efficiency of the established church, and to provide for the best mode of providing for the cure of souls, with special reference to the residence of the clergy on their respective benefices." And it was enacted by 5 and 6 Will. IV. c. 30 that during the existence of the commission the profile of dignitaries and benefices without cure of souls becoming vacant should be paid over to the treasurer with the approbation of Queen Anne's Bounty. In consequence of the recommendation of these commissions, a permanent commission was appointed by 6 and 7 Will. IV. c. 77, for the purpose of preparing and laying before the king in council such schemes as should appear to them to be best adapted for carrying into effect the alterations suggested in the report of the original commission and rected in the Act. The new commission was constituted a corporation with power to purchase and hold lands for the purposes of the Act, notwithstanding the statutes of mortmain. The first members of the commission were the two archbishops and three bishops, the lord chancellor and the principal officers of state, and three laymen named in the Act. By a later Act (3 and 4 Vict. c. 113) all the bishops, the deans of the three courts at Westminster, the master of the Rolls, and the judge of the Prerogative Court and Court of Admiralty, and the deans of Canterbury, St. Paul's, and Westminster were added to the commission, and power was given to the crown to appoint four, and the archbishop of Canterbury to appoint two additional lay commissioners. The lay commissioners are required to be "members of the United Church of England and Ireland, and to subscribe a declaration to that effect: " Five are a quorum, but two bishops at least must be present at any proceeding under the common seal of the commission, and it only two are present they can demand its postponement to a subsequent meeting. Members of the court of consistory, under the title of church estates commissioners, are also appointed—two by the crown and one by the archbishop of Canterbury. These three are the joint treasurers of the commission, and constitute, along with two members appointed by the commission, the church estates committee, charged with all business relating to the sale, purchase, exchange, letting, or management of any lands, tithes, or hereditaments. The commission has power to make inquiries and examine witnesses on oath. The schemes of the commission having, after due notice to persons affected thereby, been laid before the queen in council, may be ratified by orders, specifying the times when they shall take effect, and such orders when published in the London Gazette have the same force and effect as Acts of Parliament.

The recommendations of the commission recited in 6 and 7 Will. IV. c. 97 are too numerous to be given here. They include a revision of the dioceses, equalization of episcopal income, providing residua, &c. By 3 and 4 Vict. c. 113 the fourth report of the original commissioners, dealing chiefly with cathedral and collegiate churches, was carried into effect, a large number of canons being suspended, and some benefices and dignities suppressed.

The encllosures of these suppressed or suspended offices, and the surplus income of the episcopal sees, constitute the fund at the disposal of the commissioners. By 33 and 34 Vict. c. 124, on the surrender of any canonries, or archidiaconies, all the land and emoluments of the sees, except the patronage and lands attached to houses of residence, become, by Order in council, vested in the commissioners, who may, however, reserve the same as much as may be sufficient to secure the net annual income named for it by statute or charter. All the profits and emoluments of the suppressed canons, &c., are paid over to the commissioners, as well as the separate estates of those benefices and canons which are not suspended by this fund the canons of the see are to be paid, and the residue is to be devoted to increasing the efficiency of the church by the augmentation of the smaller bishoprics and of poor living, the endowment of new churches, and employment of additional ministers.

The substitution of one central corporation for the many local and independent corporations of the church, so far at least as the management of property in concerned, was a constitutional change of great importance, and the effect of it has undoubtedly been to correct the anomalous distribution of ecclesiastical revenues by equalizing incomes and abating salaries. At the same time it is regarded as having made a serious breach in the legal theory of ecclesiastical property. "The important principles," said Gibbes, "on which the inviolability of the church establishment depends, that the church generally possesses no property as a corporation, or which is applicable to general purposes, but that such property is a part of the ecclesiastical corporation, whether aggregate or sole, has its property annexed, distinct, and maintained. The adaption of the original endowment, was given up without an effort to do it." (Law Entitled to the Church and Clergy, p. 40)

ECLESIASTICAL LAW generally means the law of the church, in countries where an established religion is recognized by the state, but in a more general sense it would include the whole body of the law relating to religion. It is in this sense that the phrase is used by American lawyers, and it is only in this sense that it can be used of Ireland since the disestablishment of the state church in that country. The relation of the church to the rest of the law, especially in respect of legislation and judicature, is one of the most important points in the constitution of a country. Where the Roman Catholic religion is recognized by the state, the jurisprudence of the canon law prevails, but the relations between the Papal See and the state are governed by special conventions, or concordats. See Canon Law.

The ecclesiastical law of England is remarkable for its complete dependence upon the authority of the state. The Church of England cannot be said to have a corporate existence nor even a representative assembly. The Convocation of York and the Convocation of Canterbury are provincial assemblies possessing no legislative or judicial authority. The ecclesiastical judicatures are for the most part Officers by laymen, and the last court of appeal is the Judicial Committee of the Privy Council. In like manner changes in the ecclesiastical law are made directly by Parliament in the ordinary course of legislation, and in point of fact a very large portion of the existing ecclesiastical law consists of Acts of Parliament.

The sources of the ecclesiastical law of England are thus described by the leading text-writer on this subject 1—"The ecclesiastical law of England is compounded of these four main ingredients—the civil law, the canon law, the common law, and the statute law. And from these, digested in their proper rank and subordination, to draw out one uniform law of the church is the purport of this book. When these laws do interfere and cross each other, the order of preference is this—The civil law submitted to the canon law, both of these to the common law, and all three to the statute law. So that from any one or more of them, together or from all of them without attending to their comparative obligation, it is not possible to exhibit any distinct prospect of the English ecclesiastical constitution." Under the head of

---

1 The Ecclesiastical Law, by Richard Burn, LL.D.
statute law. Burn includes 'the Thirty-nine Articles of Religion,' agreed upon in Convocation in the year 1562; and in like manner the Rubric of the Book of Common Prayer, which, being both of them established by Acts of Parliament, are to be esteemed as part of the statute law.'

The first principle of the ecclesiastical law is the assertion of the supremacy of the crown, which in the present state of constitution means the same thing as the supremacy of Parliament. This principle has been maintained ever since the Reformation. Before the Reformation the ecclesiastical supremacy of the Pope was recognized, with certain limitations, in England, and the church itself claimed some pretensions to ecclesiastical freedom. The freedom of the church is, in fact, one of the standing provisions of those charters on which the English constitution was based. The first provision of Magna Charta is quod ecclesia Angli-
cana libera sit. By the various enactments of the period of the Reformation the whole constitutional position of the church, not merely with reference to the Pope but with reference to the state, was definitely fixed. The legislative power of Convocation was held to extend to the clergy only, and even to that extent required the sanction and assent of the Crown. The common law courts controlled the jurisdiction of the ecclesiastical courts, claiming to have "the exposition of such statutes or Acts of Parliament as concern either the extent of the jurisdiction of these courts or the matters depending before them." And therefore if these courts either refuse to allow these Acts of Parliament, or expound them in any other sense than is truly and properly the meaning of the words used, the whole construction of common law may prohibit and control them.

The design of constructing a code of ecclesiastical laws was entertained during the period of the Reformation, but never carried into effect. It is alluded to in various statutes of the reign of Henry VIII., who obtained power to appoint a commission to examine the old ecclesiastical laws, with a view of deciding which ought to be kept and which ought to be abolished; and in the meantime it was enacted that "such canons, institutions, ordinances, synodal or provincial or other ecclesiastical laws or jurisdictions spiritual as be yet accustomed and used here in the Church of England, which necessarily and conveniently are requisite to be put in use and execution for the time, not being repugnant, contrary, or derogatory to the laws or statutes of the realm, or to the prerogatives of the royal crown of the same, or of any of them, shall be occupied, exercised, and put in use for the time within this realm." (35 Henry VIII. c. 1.)

The work was actually undertaken and finished in the reign of Edward VI. by a sub-committee of eight persons, under the name of the Reformatorio Legum Ecclesiasticarum, which, however, never obtained the royal assent. Although the powers of the 35 Henry VIII. c. 1., were revived by the 1 Elizabeth c. 1, the scheme was never executed, and the ecclesiastical laws remained on the footing assigned to them in that statute,—so much of the old ecclesiastical laws might be used as had been actually in use and was not repugnant to the laws of the realm.

The statement is, indeed, made by Sir R. Phillimore that the "Church of England has at all times, before and since the Reformation, claimed the right of an independent church in an independent kingdom, to be governed by the laws which she has deemed it expedient to adopt." This position can only be accepted if it is confined, as the authorities cited for it are confined, to the resistance of interference from abroad. If it means that the church is distinguished from the kingdom, has claimed to be governed by laws of its own making, all that can be said is that the claim has been singularly unsuccessful. From the time of the Reformation no change has been made in the law of the church which has not been made by the king and parliament, sometimes indirectly, as by confirming the resolutions of Convocation, but for the most part by statute. The list of statutes cited in Sir R. Phillimore's Ecclesiastical Law fills eleven pages. It is only by a kind of legal fiction that the church can be said to have deemed it expedient to adopt these laws.

The terms on which the Church Establishment of Ireland was abolished by 32 and 33 Vict. c. 42 may be mentioned. By sec. 20 the present ecclesiastical law is made binding on the members for the time being of the church, "as if they had mutually contracted and agreed to abide by and observe the same," and by sec. 21 it is shown that the ecclesiastical courts shall cease after 1st January 1871, and that the ecclesiastical laws of Ireland, except so far as relates to matrimonial causes and matters, shall cease to exist as law.

ECCLESIASTICUS. See APOCRYPHA.

ECHIDNA, or PORCUPINE ANT-EATER (Echidna hornata), one of the four known species of Monotremata, the lowest order of Mammalia. It is a native of Australia, where it chiefly abounds in New South Wales, inhabiting rocky and montaneous districts, where it burrows among the loose crevices of rocks. In size and appearance it bears a considerable resemblance to the hedgehog, its upper surface being covered over with strong spines directed backwards, and on the back inwards so as to cross each other on the middle line. The spines in the neighbourhood of the tail form a tuft sufficient to hide almost rudimentary organ. The head is produced into a long tubular snout, covered with skin for the greater part of its length. The opening of the mouth is small, and from it the echidna puts forth its long slender tongue, lubricated with a viscid secretion, by means of which it seizes the ants and other insects on which it feeds. It is an entirely destitute of teeth. In its other agreeable form, with its broad feet and large solid nails, powerful burrowing organs In common with the other monotremes, the male echidna has its heel provided with a sharp hollow spur, connected with a secreting gland, and with muscles capable of pressing the secretion from the gland into the spur; but as the animal has never been observed to use this in defending itself, the spur probably serves some other purpose than that of offence or defence. It is a nocturnal or crepuscular animal, generally sleeping during the day, but showing considerable activity by night. When attacked it seeks to escape either by rolling itself into a ball, its erect spines proving a formidable barrier to its capture, or by burrowing into the sand, which its powerful limbs enable it to do with great celerity. "The only mode of carrying the creature," says Bennett (Gatherings of a Naturalist in Australasia) "is by one of the hind legs, when it may be removed to any place with great facility, for an attempt to seize it by any other part of the body, from its powerful resistance and the sharpness of the spines, will soon oblige the captor to relinquish his hold." They are exceedingly restless in confinement, and constantly endeavour by burrowing to effect their escape. From the quantity of sand and mud always found in the alimentary canal of the echidna, it is supposed that these ingredients must be necessary to the proper digestion of its insect food. The only other members of this family are the Short-spined Echidna (Echidna setosa), confined to Tasmania, and differing from the former species chiefly in the shortness of its spines, which are nearly hidden by the long hair of fur, and the Echidna Bruijni—a new species discovered in 1877 in the mountains on the north-east coast of New Guinea, at an elevation of 3500 feet. By many naturalists the generic term Echidna has lately been abandoned in favour of Tachyglossus of Illiger.
Echinodermata

Echinodermata (from ἕχον, a hedgehog or sea-urchin, and δέρμα, skin,) a class of marine animals which constitutes with the class Scelentera the sub-kingdom Annelidea of Haeckel, or, according to some authorities, is a distinct sub-kingdom of the Invertebrata. Familiar examples of the Echinodermata are the Sea-urchins, Star-fishes, Feather-stars, and Sea-cucumbers of the coasts of Britain. The characteristics of the group may be briefly summarized thus. The adult presents a more or less marked, although never perfect, radial symmetry of parts; the larva, in most instances, is bilaterally symmetrical. The perisome or derma develops a calcareous skeleton of numerous interlocking plates or of detached plates or spicules. The muscular tissues consist chiefly of unstripped fibres. The intestinal canal, opening in a distinct anal aperture. An aqueous or ambulacral system of organs, regarded as homologous with the water-vascular system of the Scelentera, is generally present; and there is a nervous system consisting of a ganglionated circular or polygonal cord, which surrounds the mesentery, and sends off branches parallel with and superficial to the ambulacral canals. The sexes are in the majority of cases distinct, and the reproductive organs are generally placed symmetrically with respect to the radially disposed skeleton.

In all Echinodermata of which the life-history has been worked out, the larva, echinoplum, or, as it has been termed by Sir W.J. Thomson, the pseud-embryo, produced from the egg is, with but one or two exceptions, ovate, free-swimming, and provided with cilia, which become after a time confined to one or more bilaterally symmetrical bands running transversely or obliquely to the long axis of the body, and frequently borne on processes of the same. In the Asteroidea and Holothuroidea the larva is vermiform and devoid of skeleton; in the Echinoidea, it is plateform (Latin, platus, a pente-house, or breast-work), and has a continuous calcareous skeleton, passing into and affording support to the body processes. A stomach, with an oesophagus and intestine, which make with each other an angle open towards the ventral side of the body, is early developed in the Echinoderm larva. The peritoneal cavity and ambulacral system of vessels are developed from diverticula of the alimentary canal. A tube formed by the integument of the pseud-embryo to one side of the dorsal line may remain connected with the ambulacral system of the adult as the madreporic canal. In the Echinoidea, Asteroidea, Ophiuroidea, and Crinoidea, the body-wall of the adult is formed from the blastemata, the larval body, more or less of the intestine, and, when present, the skeleton are cast off or absorbed into the new organism, and another month appears in the centre of the circular vessel. It is by this peculiar metagenetic mode of development of the Echinoderm within its larva that the class Echinodermata is specially allied to the order Tubulifera and Testacea of the class Scelentera.

The Echinodermata may be divided into the following orders:—(1) Echinoidea, or Sea-urchins; (II) Asteroidea, or Star-fishes; (III) Ophiuroidea, or Sand-stars; (IV) Crinoidea, or Feather-stars; (V) Cystidea; (VI) Echinoasteridea; (VII) Blastocystidea; (VIII) Holothuroidea, or Sea-slug. Of these orders V, VI, and VII, have been extant since the Palæozoic period, by some authorities the Echinoasteridea are included with the Cystidea.

Order I.—Echinoidea.—The body in the Echinoidea is spheroidal, oval, discoid, or heart-shaped, and the shell, test, or perisome bears numerous spines. A common European type of the group is the species Psammechinus (Echinus, L.) esculentus (see fig. 1). In certain forms (Scutella) the test is perforated by slit-like apertures, and curiously lobed or digitate (fig 2). With few exceptions the test is a rigid structure of numerous plates united by their edges. In the Echnotheuridae, however (Calcearia, Phoramecina, and the ex-

tinct Echinotheuridae and Lepidocentra), and also in the Palæozoic genera Archaelaurus, Lepidocystidea, and Lepidocerus, the plates of the corona overlap, so as to resemble the peristomial plates of Calcearia.

The plates are composed of a dense calcareous network, consisting chiefly of calcium carbonate. As the test is invested with an epidermis, and is produced mainly by calcification of the mesoderm, it is to be regarded as an integument or endo-skeleton. In the typical Recent echinida the walls of the corona or main body of the shell, when freed from spines, are seen to consist of five zones or arcs, the ambulacra (Latin, ambulare, a walk), composed of double rows of pentagonal plates, and alternating with five other double rows, the interambulacra. In the Palæozoic forms, which constitute the sub-order Pericechinidea of McCoy, the interambulacrum is made up of more than two rows of plates, of which the intermediate and central are hexagonal in form (see figs. 3 and 4). In the genera Astoeides and Ophiopus there are extra ambulacral as well as interambulacral plates. The ambulacra, which
ECHINODERMA T

are usually narrower than the interambulacra, have near
their outer edge small shield-like spaces, _ambulacra_, bounded by
a more or less elevated wall, and perforated by pairs of
small orifices or pores for the protrusion of the feet or
pedicels, each pair of pores corresponding to one of the pore
plates—the primitive ossicles which commonly unite to
form the ambulacral plates. The ambulacra are either
homogeneous, i.e., composed of similar elements gradually
diminishing in size towards the poles of the test, or (as in the
_Spatangoida_ and most of the _Clupeasteroida_) are hetero-

geneous, having the upper portion petaloid in shape, and
the lower with pores scattered in areas not always confined
to the ambulacral plates, or arranged in ramifying fasciculi.
In the _Spatangoida_ the anterior unpaired ambulacrum is
commonly obsolete (see fig. 5). In the Oolitic genus

**FIG. 5.—Spatangoidea purpurascens.**

**FIG. 6.—Pedicellaria of**

**FIG. 7.—Echinoidea pur-

_Dipsaster_, the two postero-lateral ambulacra, forming the
_ambulacra_, are separate from the rest, and converge over the
anal opening; while the three anterior, the _truncum_, unite at the anal disk (see fig. 8). The growth of the
urchin in length is effected by the formation of new
plates at the apical end of the corona, and in breadth by additions to the margins of the plates. On the surface of
the plates are tubercles of different sizes, each with a
knob or elevation, sometimes crenulated, by which the
acetabulum of the spine is attached (see figs. 4 and 5).
The presence or absence in the tubercle of a central perforation for the passage of a ligament for the spine is an important
distinguishing character in various groups of fossil echinida. The
spines in the young state are dilated, like the plates of the
test; they are composed of a calcareous network, and are
penetrated and covered by the perisons, which contains the
muscular fibres by which they are moved. They are short in
the _Clupeasteroida_ and _Spatangoidea_, and of various
lengths in the _Echinoidea_, and offer a considerable diversity of
form and ornamentation. Dr Gray (Ann. of Nat. Hist.,
1844) mentions the discovery in Sicily of the fragment of
a spine of an echinus, the circumference of which was
nearly 1 1/2 inches, and the length more than 8 inches. In
_Porocidaris purpuracea_, a deep-sea form, the spines are
paddle-shaped, and very flat, and are serrate on the edges; in _Colobopora_
the long curved spines resemble the antennas of certain beetles. Scattered
over the surface of the test, and more especially on the oral membrane, are the
pedicellaria, generally regarded as peculiarly modified spines; these, when well
developed (fig. 6), consist of a long flexible stem, fur-

**FIG. 7.—_Echinoidea pur-

ished at the summit with a forceps of three pinces or
prongs, which snap together, and seize firm hold of
any object that comes in their way. They serve for the
removal from the neighbourhood of the shell of dirt of
all kinds, and apparently also for defence. _Ctenella
frequenta_ has pedicellaria with four valves. In some
_Spatangoidea_ genera the corona bears symmetrical hands of
minute tubercles with attached spines, the _sumneria_ or _fasci-
des_, distinguished, according to their position with re-
spect to the anus or to the apical or the marginal termina-
tions of the pedaloid ambulacra, as _sub-anal_, _circum-anal_,
_intropetalona_, and _peripetalona_. The spines on the _sum-
neria_ have a thick integumentary covering, and except at
the enlarged apex, are closely studded with cilia. Lovén has
shown the occurrence, in all Echinidea but _Culoria_, of
another kind of appendages of the test, possibly sensory
organs, to which he has given the name of _phaloria_.
These are button-like, sphaeroidal bodies, seldom above 1/3
inch in length, furnished with a short stalk, and normally
articulated with small projecting tubercles on the plates of
the ambulacra and peristome. Sometimes they become
concealed by a layer of the test, in which there remains
only a fine external fissure. At the summit or apical pole
of the test is a space occupied by the ocular and genital
plates, which in the _Echinidea_ (Endocyclica) encircle the
anus with its anal plates. The five genital plates, which are
opposite the interambulacra, or interradial in position,
are perforated by apertures for the exit of the reproductive
products. In the _Clupeasteroida_ and _Spatangoidea_ (Exo-
cyclica), in which the anus is eccentric, and exterior to the
apical disk, one of the genital plates is usually imperforate
(fig. 7). The five ocular plates are situated radially, crown-
ing the apical ends of the ambulacra; on the surface of each is a
depression, having a pore for an ocellus or eye-spot. Always,
except in the _Clupeasteroida_, the right antero-lateral genital plate,
or, in other words, that situated to the right of the anterior
ambulacrum of the trivium, is larger than the others, and bears the
convex, perforated _mandibulopetalous tubercles_ or _madro-
epetalous_. In the _Clupeasteroida_ this is most fre-

**FIG. 6.—Pedicellaria of

**FIG. 8.—_Echinoidea pur-

quently extended over the other apical plates. The hinder genital plate, with apparently
one exception, is wanting in the _Spatangoidea_, the place being
occupied by the madreporite. The Paleozoic _Echinidea_ differ from the modern forms by the greater number of
perforations of their ocular and genital plates. At the base
of the test is the mouth with its buccal membrane and plates.
The species _Lessina mirabilis_ (the type of the sub-family
_Lessinidae_, family _Spatangoidea_) has both mouth and anus
closed by converging triangular valves. In the _Echinidea_
_and Clupeasteroida_ the mouth is central in position, and
provided with teeth; in the _Spatangoidea_ it is eccentric and
edentulous. The teeth resemble those of Rodents in form,
and are arranged in hard wedge-shaped sockets or _alveoli_,
which by their union form a pentagonal cone. As the outer
substance of the tooth is harder than the inner, it is less
readily worn away, and thus always presents a sharp edge
Each alveolus is composed of two halves united in the
middle line, and each half, again, consists of a superior and
inferior portion. The alveoli are inter-radial in position,
or opposite the interambulacra. They are connected by
transverse muscular fibres, to alternate with superiorly
placed, thickish, radial structures, the _rotula_ or _folia_, which,
in the _Echinidea_, bear each a bifurcated piece, the _radus._
This skeletal mouth-apparatus is commonly known as
"Aristotle's lantern." The calcified internal arched processes termed "auriculae," at the oral end of the ambulacra in the Echinidea (of the interambulacra in Cidarida), regarded as homologous with the internal ambulacral ossicles of the Asteroidea and Ophiuroidea, are formed of two pieces from the top of the auricular pass retractor muscles to the outer edge of the alveoli. The oral skeleton is provided also with retractors proceeding from the alveoli to the lower interambulacral edge of the corona, besides special muscles connected with the radii. In the Clypeasteroida arched (in Cidarida unarched) processes are given off from the ambulacral plates, at the sides of the ambulacral canals; and in the Clypeasteroid genus Scutella, the dorsal and ventral walls of the corona are connected by vertical calcareous plates or trabeculae. None of the above-mentioned internal calcareous processes is developed in the Spatangoidea. The mouth communicates by a tortuous oesophagus with the stomach. The intestine forms a sort of tube on the inner side of the shell, and is attached to it by a tentacle.

Of the internal organs of the Echinidea the most important and characteristic are those constituting the ambulacral system. These are (1) a circular or slightly pentagonal vessel placed around and traversed by the oesophagus, on the inside of the alveoli, and between the nervous and blood-vascular systems, called either the vessel (absent in the Clypeasteroida and Spatangoidea), answering to the racemose appendages of the Holothurians; (2) the membranous or calcareous madreporic canal, termed also the sand-channel, which runs nearly vertically through the axis of the body, and, communicating with the exterior by the madreporic tube, supplies water to 1, 2, (4) vessels radiating from 1 along the parieties of the body, and opening eventually into basal sacs, or ampullae, proceeding from the canals of the pedicels shortly above their origin. In the vessels of the ambulacral system is contained a watery fluid stratified from the perivisceral cavity. The pedicels, which may vary considerably in shape, are tubular structures, usually terminated by a sucking disk, they have contractile, muscular walls, and are capable of being protruded beyond the extremities of the spines. They subserve locomotor, tactile, or branchial functions. The contractile perivisceral fluid is kept in motion in the cilia lining the lining membrane of the body and the viscera. Where modified pedicels or ambulacral gills are absent, as in the Echinidea, the Cidaridea excepted, a scarcity of that fluid is apparently promoted by branchial developments from the peritoneum, the hollow stems of which communicate with the body-cavity. The nervous system consists of a slender, pentagonal, red or violet hoop around the gutter, superficial to the circular ambulacral vessel, with five ganglia sending off as many cords, which pass in their course through the ambulacral pores, probably supplying the pedicels, spines, and pedicellariae, and terminate eventually in the pigmentated eyes-spots. The principal vessels of the pseud-hemal or blood-vascular system of the Echinidea appear to be two trunks, the one on the dorsal, the other on the ventral side of the alimentary canal, these, according to Hoffmann, communicate either directly or by a distinct trunk with the water-vascular ring.

From an examination of Echinus synurus, Pentamachus milleri, Teuthogena licida, and Amphiura corticata, Ferner determined that, as maintained by Hoffmann, the circulatory and nervous systems are identical, that the so-called "heart" is only a gland, which opens by a canal into a funnel-shaped space bounded by the lining membranes of the test and the madreporic, through which floats freely in the perivisceral cavity. Further, he found that the ambulacral vessels and their branches terminate blindly, the circulation consisting solely in a to-and-fro movement of their contents.

The reproductive organs are large racemose glands, situated beneath the upper termination of the interambulacra, and opening externally by the genital pores. The sexes are distinct. The spermatophores have vibratile filaments; the egg is fertilized after leaving the body of the female, and in about eight hours undergoes complete yolk-division.

The pseudo-embryo or echinoembryum, at first created and spherical, becomes after a time wedge-shaped, at its broad end to the mouth or pseudopore. Simultaneously with these the skeletal rods and calcified bands of the phalices begin to be produced. The development of the ambulacral system commences with the formation of a sac which lies to the left of the junction of the pseudo-embryonic gut and somach, and is prolonged into a canal opening by a pore at the oral end of the ambulacral system, the canal of the sac becomes the madreporic tube. The skeleton of the phalices separates, as development proceeds, into several pieces, and is by degrees discarded, while its process advance, and the body assumes the rounded form of the embryo within. Thus, however, in many cases to undergo similar important changes before its resemblance to the adult is complete. Thus in the young of species of Spatangoidea, the peritoneum is almost central, and is pentagonal in form. In the Echinidea, before the appearance of the anus in the embryo, its place is occupied by a single plate, the sub-anus, and the anus appears near its border, towards the posterior right ambulacrum. It lies within a circle formed by the imperfect peritonea, the future genital plates, and these again are surrounded by five imperforate oval plates, with intervening oval plates. The central anus, however, is sometimes arabulacral, such as Salenoida among the Echinidea. If it be considered as homologous with the dorsal-external plate of Monopora, or the basall of the cally in other Ophiuroidea, the genital plates correspond to the phalices, and the ocular to the first radials. The food of the Echinidea consists either of seaweed, and small shellfish and crustaceans, which are conveyed to the mouth by the pedicels, or, as in the case of the cuticular forms, of sand and earth containing nutritive material. In the species Aninura, one of the Us ELSE, Hoffmann discovered the presence of a muscular chamber at the apex of the test, containing embryonic in various stages of their growth. Certain species, observed by (Clypeasteridae, and Echinidea) have become at every egg-rolling for themselves: mainly the eggs of the echinoderms are a "remedy for the stone, and "filsms in horses' eyes." They are put to practical use in some countries as stone-penics.

Various systems of classification have been adopted for the Echinidea. In the following scheme the principal groups are arranged chiefly according to the position of the anal opening and the nature of the ambulacra.

Sub-order I — TESSULATA  Echinidea with interambulacral of more than two rows of plates.

Sub-order II — TYPICA Echinidea with interambulacral of but two rows of plates.

Group I — REGULARIA or ECHINOCYCLAE  Mouth central or subcentral, anus usually central and opposite the mouth, and never exterior to spiny disk.

A. Anus central

1. Shell round

Cidaridea  Tubercles smooth, pr-retractor, peritoneum notched, anal plates ten, aneurys inclosed, lateral branchial absent.

Dendroaster  Tubercles crassulate, pr-retractor, peritoneum notched, spines hollow. Allied forms are the fossil H. hennikeri.
Echinoidea

Arbocidate Tubercles smooth, imperforate, four large anal plates, usually closed.

Echidnae Tubercles imperforate, or perforate and crenulate, anal plates numerous, pairs of pores in ranks of four, six, or more.

ii. Shell oval or elliptical.

Echinoidea. Pores in ranks of five or six pairs.

B. Anus eccentric through intervention of one or several supernumerary anal plates.

Solasteridae All fossil forms, with exception of the genus Scoloplos.

Group II.—Irregularia or Eocyclidea. Anus eccentric, not within the anal disk.

A. Ambulacra simple, not petaloid

Galeridae Mouth central; shell globular or sub-pentagonal; a single apex at which the ambulacra converge.

Dysasteridae Mouth eccentric, shell ovate or heart-shaped, two spaces, at which the lamina and trivium respectively converge.

B. Ambulacra more or less petaloid.

1. Dental apparatus present.

Glyposasteridae Shell more or less flattened, sub-pentagonal.

Sulcidae Shell depressed, discoidal, often digitate or perforated, lower surface with ramifying grooves.

ii. Dental apparatus absent.

Culcubidae Mouth central or nearly so; perisome sub-pentagonal.

Spirasteridae Mouth eccentric, transverse or reniform.

To the group Regularia must be added the Cretaceous and Recent family of Echinoidea. The Echinoidea are represented in Paleozoic rocks by the sub-family Echinothuriidae, the group Echinoidea, and the order Echinidea. The most important and characteristic genera of the Echinoidea are Echinothrus and Echinothurea.

The Echinoidea is a group of marine invertebrates, primarily echinoderms, known as sea stars. These animals are characterized by their five-rayed symmetry and five ambulacra (pairs of tube feet). The Echinoidea includes the orders Echinidea, Echinochordata, Echinoidea, Echinoidea, and Echinidea. The orders Echinidea and Echinoidea are the most common and widespread groups within the Echinoidea, with representatives found in both the Paleozoic and Mesozoic eras. The order Echinidea includes the class Echinidea, which contains the sub-class Echinoidea, and the order Echinidea includes the class Echinidea, which contains the sub-class Echinidea.

The Echinoidea are known for their radial symmetry and their ability to regenerate lost body parts. The radial symmetry is evident in the five-rayed structure of their body, which is composed of a central disc and five arms. The arms are equipped with tube feet, which are used for locomotion and feeding. The Echinoidea also have a unique water vascular system, which allows them to move and filter water for food. The Echinoidea are found in a variety of marine environments, from shallow coastal areas to deep oceanic regions.

The stomach in most star-fishes is produced into five sac-

cular prolongations (cardinal sacs), above these it con-

tracts, but again dilates to form the pyloric sac, which

open out in each ray into a pair of parallel diverticula having numerous caecal dilatations, and connected by a mesentery with the ambu-

lacer ossicles, which have a nervous external and muscular

surface of each ambulacral ossicle, and lying alternately

external and internal to one another in position on succes-

sive ossicles (fig. 15). The mouth, which is devoid of den-

tary apparatus, is situated in the middle of a membranous

disk in the centre of the oral surface. It leads by a short
gullet into the stomach. The stomach in most star-fishes is produced into five sac- 
cular prolongations (cardinal sacs), above these it con-
tracts, but again dilates to form the pyloric sac, which

give rise to five tubes, which open out in each ray into a

pair of parallel diverticula having numerous caecal dilata-
tions, and connected by a mesentery with the ambu-
lacral ossicles, which have a nervous external and muscular

each ray underlies a strong band of transverse fibres, by which it is separated from the

ambulacral canal above. At the extremity of the ray the nerve terminates in an eye and its tentacle. The eyes are

small processes of the ectoderm, having a convex surface or cornea containing a large number of simple, conical,

pigmented ocelli. In the peritoneal cavity and ambulacral vessels is a watery fluid containing corpuscles. Respiration
appears to be effected by means of water supplied

VII — 82
Echinodermata

The interior of the body is lined with the plates of the perisome. In Solaster water can enter the body cavity by the interbrachial creniform plates through which the genital ducts pass.

Among the Astereida several modes of development have been observed. In some species the larva appears at times to be formed of the rays. The species Petelella ciliata hatches its young in a special pouch on the dorsal surface. The larva leaves its egg by a tube, but subsequently assumes a pentagonal form, and the provisional mouth comes to be placed at one side of the body. Central mouth and stomach afterwards developed open into each other at the time that the young star leaves the maternal pouch. In other cases the breeding-chamber may be formed by the bringing together of the bases of the rays, and the uniliated embryo develops at its anterior end club-shaped tubercles, by which it can attach itself to the breeding-chamber or to substrata objects. Until these processes appear the breeding-chamber remains closed. In general, the larvae of the Astereida begin life as a lobed and ciliated pseudo-embryo, a common form of which is the Bythocystis. Another form, the Brachiosoma, is distinguished principally by three tuberculated processes at the anterior end of the body. The ambulacral vessels of the adult are developed in the pseudo-embryo from a portion of one of the diverticula of the stomach in which originate the postanal canal and the whole or great portion of the mesodermic structures.

The Astereida are classified by M. Edmond Perrier as follows—

**DIVISION I**—Pedicellata pedunculata; pedicella (except in Echinaster and Pedicellaster) quadrangularly ambulacral.

**Asteria.** Ex Asterias (Asterichonechus), Holaster, Calveasterias, Anasterias, Labridaster, Pedwellaster.

**DIVISION II**—Pedicellata sessiles; pedicella of the same form as the peduncle.

1. **Dorsal skeleton reticulate**

2. **Dorsal skeleton of longitudinal series of rounded or quadrangular ossicles, usually unincinated.**

3. **Skeleton, at least of lower surface, of incised ossicles; dorsal and ventral marginal plates very distinct.**

4. **Sk. ossicles imbricated; with spine on the free border, or rounded and completely covered with small spines.**

5. **Skeleton of exoskehd.**

6. **Dorsal investment supported by spines radiating from the prominent skeletal ossicle.**
   Pyasterias. Ex. Pyasteris.

7. **Arms long, straight, distinct from disk, with minute spines or dorsal series.**

Of the Astereida (fig. 17) — The Astereida are represented in the Lower Silurian series of strata by the genera Echinaster, Palaster (including Calveasterias), Sistaster, Tenuaster, and Ostracasterias, in the Upper Silurian by Ophioaster, Palaeaster, Palaeomus, Petaster, Palaima, Leptaster, and Solaster; in the Devonian by Acanasterias, Palaeaster, Asterias (also in Carboniferous), and Holaster, in the Carboniferous by Schwanaster and Cretasterias, by Quinaster in the Triss, by Tropaster in the Liass; and by Asteropeten with other still living genera in the Liass and Liasterias. The Cretaceous strata are more characterized species of the recent genera Asteroidea, Ophioasterias, Goniasterias, and Stellasterias.

**Order III.**—Ophiuridea. The brittle stars (fig 18) have a general external resemblance to the Asterida. The body consists of a central disk with five or more simple or less usually ramifying rays, which are sharply distinguished from the disk, and are without ambulacral grooves, and contain no prolongations of the stomach. Spaces and plates, also hooks (considered to be the representatives of the pedicellaria of the Astereida), are developed in the perisome. The dorsal skeleton of the arms is constituted usually of a ventral or supernambulacral row of plates, a dorsal median or antambulacral row, and two side rows of spinous imbricated plates. More rarely the perisome of the arm is leathery in consistence, and bears small plates, of which the ventral are the largest, and perforated with a double line of pores. The internal axial skeleton is formed by the vertebro-axial ossicles (fig. 15), the right and left halves of which are united by a longitudinal suture. The axial ossicles are articulated to one another by means of peg-and-socket joints. On the lower surface of each, corresponding to a depression on its dorsal surface, there is a groove for the passage of a radial ambulacral vessel and a nerve. The innermost of the axial ossicles is in two articulated halves, and the neighbouring halves of every two arms are connected with a couple of interambulacral pieces, with the inner edges of which is articulated a single ossicle, the torus angularis. The last-mentioned bears the papilla angularis, and beneath these the palpe angularis, which are short flat processes, moved by muscles, and serving as teeth (see fig. 20). Right and left of the origin of each arm; within the body disk, on the ventral side, is an elongated ossicle, which in the Parasteridae unites at the margin of the disk with an arched piece running towards the centre of the dorsal surface. The mouth is in the centre of the oral face, and at each of its angles is a pair of tentacles. It leads into a simple sac-like alimentary canal, which is without anus. The madreporic canal, the walls of which are strengthened with calcifications, leads from the surface of one of the interradially situated seta buccalia on the ventral side of the disk into a circular ambulacral canal, upon which rest minute plates, the homologues of the Holothurian calyces. Opening into the circular ambulacral canal, and corresponding in position to the madreporic canal, there

**Fig. 18.** — Ophiohols bells, upper surface.

**Fig. 19.** — Axial ossicle of Ophiohola. (After Müller.)

A. dorsal surface; B. ventral surface; C. ventral groove; D. facet for tentacle.
ECHINODERMATA are usually four interradially placed Polian vessels. The necks of the Polian vessels and the ambulacral ring give off the diverticula termed by Sunrock as ambulacrala ecm. From the ambulacral ring proceed the five radial canals between the superambulacral plates and the axial canals. In front of each oscule they give off right and left branches to the pedicles. These are tentacle-like, devoid of basal vessels, and, except in the Euryalidae, pass out through openings between the superambulacral and lateral plates. The nervous system consists of an oral ring, which supplies a branch to each arm, running superficial to its radial ambulacral canal. Between the nerve and the latter is a neural canal. The genital organs are pairs of racemose glands attached to the inner dorsal surface of the disk; their products are shed into the perivisceral cavity, whence they make their way through the genital canals between the origins of the arms.

Hemaphroditism has been observed in the species Ophiolepis symmetrical and in some genera, as Ophiocoma and Ophiohima, simultaneous reproduction occurs. According to Lutken, this at an early age is more especially exhibited by the ovi-ogons forms. In certain cases development takes place within the egg, without any free pseudoprotocelomic stage, but most generally metamorphosis from a plankton larva takes place. The bilaterally symmetrical skeleton of the plates consists of eight radially divergent calcareous rods. The development of the embryo commences with the production of two coelomic cavities, one on each side of the gill slit, which form cellular blastomere masses, one behind and the other in front of the stomach, and a third to the left of the pseudocoel. The ambulacral system of the adult is developed from the last of these, which unites with the mass in front of the stomach to form the ventral portion of the body, whilst the posterior mass furnishes the dorsal portion.

The Ophiuridae may be classified as follows:

Sub-order I.—OPHURIDE. Arms unbranched, ambulacral furrows covered with plates, genital clits ordinarvly fire, but creeping.

A. Oral cloths armed

(i) No papillae antimeres

OPHURIDAE. Bucca; stactes trigonal, disc granulated Ex Ophiura (Ophiocoma), Ophiocoma, Ophiopmna.

(ii) Bucca; stactes pentagonal, disc scales naked Ex Ophiolepis, Ophiocoma, Ophiura.

APPENDICIDE. Disc ragged and scaly, ray plates grannated Ex Ambiphora, Ophiocoma, Ophiocoma.

OPHIOLEIDAE. Bucca; stactes naked, ray cloths with soft integument Ex Ophiocoma, Ophiocoma.

(3) Papillae antimeres present

OPHIURIDE. Disc covered with solid plates Ex Ophiocoma, Ophiocoma, Ophiocoma.

Sub-order II.—EURYALIDE. Arms simple or ramified, and capable of being rolled up towards the mouth, ambulacral furrows covered by soft integument. Spines are not present, but there are tufts of papilla on the ventral surface of the arms, genital clits ten.

Annulidea, by Astrophyton, Troyaster, Asteroidea, Asteoridida, Asteoridida, Ophiocoma, Ophiocoma, and other genera.

Distribution in time of Ophiuridae.—The following Palaeozoic genera are commonly referred to the Ophiuridae.—Pre-Cambrian (Lower Silurian), Paleohoria, Aenura, and Exstrella. Devonian or the same (Upper Silurian), Auspaya (Devonian of New York) Ophiura occurs in the Carboniferous Limestone of Rockies. In the Mesozoic, the Astrophyton, by Astrophyton, Troyaster, Asteroidea, Asteoridida, and in higher Secondary strata Ophiocoma, Ophiocoma, Ophiocoma, and other genera.

The Ophiuridae and Asteridea possess, in a marked degree, the power exhibited by the whole of the Echinodermata of reproducing lost portions of the body. The former have received the name of the Brachioidea. On account of the remarkable facility with which species of the genus Ophiocoma are capable of laying away their arms entire, but, at will, rapidly break them into little pieces. The same property has been noticed in the genus Luides among the star-fishes, in the Crinoidea genus Comaster, and the Synaptidae among the Holothuridea. Writing of a species of Luides, Prof. E. Forbes remarks: “The first time I ever took one of these creatures I succeeded in getting it into the boat entire. Never having seen one before, and quite unconscious of its suicidal powers, I spread it out on a rowing bench, the better to admire its form and colours. On attempting to remove it for preservation, to my horror and disappointment, I found only an assemblage of rejected members. My conservative endeavours were all neutralized by its destructive exertions, and it is now badly represented in my cabinet by a dusky arm and an armless disk.” Major Fred H. Lang relates (Nature, Oct. 12, 1876), that during a dredging expedition in Torbay, presuming on the fact that as a rule he could take up the specimens of Comaster, Ophiocoma and Ophiocoma with his hands without occasioning their dismemberment, he “put about a hundred of the two sorts into a sponge-bag, but this was asking too much of them,” for on reaching home he found “that both Feather-stars and Bottle-stars had convulsed themselves into a mass of muce-meat! It would have been difficult to find a single portion of an arm or a quarter of an inch long.”

Order I.—ECHINODERMATA. The body in the Crinoidea is ciliated, shaped or burrow-form, and its base always in the young state and usually in the adult is attached by the apical pole either directly or, as more commonly, by means of a calcareous stem to submarine objects. The inferior or oral plate of the body or calyx is formed of polygonal plates articulated by their edges, and the superior or ventral plate or disk, which may be either flat or arched, is formed either by a personal membrane, occasionally strengthened with scattered calcifications, or, as in the Terebella, by regularly arranged plates, resembling those of the inferior wall. At the border of the calyx are 2-18, usually 5, arms or branches, which are movable, and can be closed together over the oral disk (fig 22). Between them, commonly in the centre of the disk, in the mouth, and near it, in one of the interradial spines, in the arms. It has been shown by Sir Wycliffe Thomson, (Phil. Transn vol. clv pt 2), that the skeleton of Asteridea and Echinidea may be divided into two systems of plates, the radial and the perisomatous. The former including all the surface of the stem, the conical plates, the radial plates, and the points of the arms and pinnules, and the latter the basals, oral, and anal plates, and the interradial and other plates or spines developed in the disk-membrane. The body of
ECHINODERMATA

636

the pentaceroid is at first, while yet included within the pseudomere, and during its earliest fixed stage, surrounded and enclosed by plates of the pseudome system alone. The predominance of the pseudome system in the calyx of the older Crinoids and formally to them is hence a fact of considerable interest to the embryologist.

The stem is made up of numerous ossicles articulated and interpenetrated by elastic fibres and soft connective tissue. It is attached at its distal end by a root-like expansion, or by numerous, filamentous, branched cirri, having joints similar to those of the stem. Other and unbranched cirri are attached in whose to many of the ossicles of the stem. Through the centre of the stem runs a canal containing a soft solid substance. In the adult Antedon, as has been pointed out by Dr Carpenter (Proc. Roy. Soc., 1876), the medullary portion of the Crinoidal axis passes up through a pentagonal five-chambered dilatation of its cortical portion within the centro-dorsal plate, and reaching the cavity of the calyx, forms the pedicel by which chiefly the stem runs a canal into the axial canal by which chiefly the stem runs a canal into the axial canal by which chiefly the stem runs a canal into the axial canal by which chiefly the stem runs a canal into the axial canal by which chiefly the stem runs a canal into the axial canal. The pedicel enters the calyx and passes through out its entire length, more or less imbedded in its walls, to the commencement of the subtentacular canals, where it apparently becomes continuous with the generative piers of the disk. The stem varies in length, being short in Apecinus, long in Pentacrinus; it is round and sometimes moniform in most Palaeozoic Crinoids, but in Plageryrinus compressed as it nears the calyx; in Woodocrinus it tapers from the calyx downwards. In the Palaeozoic Crinoids the articulations of the ossicles radiate from the central canal, which is larger than in the more modern forms. In the Mesozoic genera the articular facets are commonly united by crescentic or stellate ridges. In the Silurian genus Perichocrinus the ossicles of the stem are alternately thicker and thinner. The calyx, which may be regarded as formed of the uppermost ossicles of the stem, is composed of several series of plates. The lowest of these is commonly formed by 2-6 pieces, the basalia, which in Rhassicrinus appear to be represented by a single central plate. The basalia in the Tesselata are succeeded by the parabasalia or sub-radialia; after the basalia or these come one or more rows of plates (in Rhassicrinus three), the radialia (see fig. 23). In Pentactinurus the radialia seem to form the commencement of the calyx. Supported by the radialia are series of arm plates, or brachidia, from the uppermost of which, as in Pentacrinus, may bifurcate the palamae. The ossicles of the arms are sometimes single, sometimes united by syngenes, or immovable sutures. In the Silurian genera Antocrinus and Cretacrinus the subdivisions of the arms are very numerous, and by their lateral articulation form web-like expansions.

The arms of Poteriocrinus phatius bifurcate 4 times, giving 80 rays; the total number of plates in that species has been estimated at 1300 (see J. G. Groomfett, Rep. Brit. Assoc. 1875, p. 65). In the calyx of the Tesselata there are plates, interradialia, present between the radialia. In Antedon the central portion of the viscera is contained in a basin formed by the 1st, 2d, and 3d radialia, and by the 1st and 2d pairs of brachidia, and the basal segments of the pinnules borne by the second, and the pinnules cavity is completed by the perissome uniting the basal segments of the arms. Where, as in the Articulata, represented by the modern Crinoids, the disk is more or less membranous, four or five deep furrows radiate upon its surface from the mouth, which pass on to the oral surface of the arms and extend to the extreme of their pinnules. They carry the hollow ambulacral tentacles, which pass out through pores in the perissome. In 1865 Mr J. Rofe demonstrated (Geol. Mag., 1845) in the case of several genera of Tesselata Crinoids from the Mountain Lime-stone (Actinocrinus, Amphoraecrinus, Cyathocrinus, and Plageryrinus) that the grooves on the upper surface of the arms divide at their base into two channels—(1) a superior channel passing up beneath (in some cases partly within) the plates of the dome or disk to its apex, and there uniting with an internal circular aperture, probably the mouth; and (2) an inferior channel which goes direct into the visceral cavity. These channels, since their discovery by Mr Rofe, have been shown to be generally present in the Tesselata Crinoids. The superior channels, on the supposition that the central opening is a mouth, doubtless served for the supply of food and of water for respiration; whilst the inferior channels probably gave passage to the motor muscles of the arms, and placed the visceral cavity in connection with the ovaries, if the latter, as in modern Crinoids, were situated in the arms. In the Palaeozoic genus Rhodocrinus the arm is cylindrical, and without a groove on the upper surface, but immediately below its base is situated the orifice of a passage which turns towards the arms. What in the Palaeozoic Crinoids is commonly regarded as the anal opening is situated at the extremity of a proboscisiform tube (fig. 24) inter-radially placed, and often of great length—as much as 4 inches in Poteriocrinus phatius. In existing Crinoids there are two apertures in the disk, the mouth, usually central, and in Rhocols, and the inter-radially situated anus. The mouth is closed by lobes of the perissome, the oral valves, which may contain calcareous plates. Between these run the oral or ambulacral grooves from the mouth to the arms. In Antedon (Comatula) the alimentary canal passes obliquely downwards from the mouth, then horizontally, and after more than a complete turn bends upwards again, and ends in a rectal chamber terminating in a spout-like prominence. Between the exterior of the mucus wall of the alimentary canal and its peritonal covering is the intramural space. The double wall of the canal is strengthened by calcareous disks; and it is by the folding of the inner side of the wall, and the resultant piling together of layers of these plates that the vertical columnella is produced. The body cavity is lined by a smooth peritonal membrane. The ambulacral furrows are bordered by plates, the ambulacral or marginal lamellae, as in Rhassocrinus and Pentacrinus, or, as in Antedon, by elevated ridges of the perissome, produced at the edge into a series of small lobes or valvules, and having grouped on their inner side the pedicels. The epithelial floor of the grooves, where there is good reason to believe, is lined with cells, which, like those of the gullet, serve to create currents in the water and thus to bring into the mouth Diatomaceae, spores of Algae, minute Entomostraca, and other nutritive matter.

In Antedon, as has been shown by Dr Carpenter...
ECHINODERMATA 637

(fig 25), the tentacles communicate at their bases with a common trunk, the tentacular canal. Beneath this, but in communication with it, lies the subtentacular canal, which is usually divided by a more or less incomplete septum. Each of the subtentacular canals is continued with a branch of the axial canal, which communicates with the dorsal portion of the perivisceral cavity by means of a minute pore situated nearly at the centre of the lower surface of the visceral mass, and partly occupied by the pedicle before referred to. As the axial canal extends downward through the visceral mass it comes into contiguity with the alimentary canal, and opens into it by irregular passages. There is in the arms a third canal, the coelomic, which is a continuation of the body-cavity or coelom, and is separated from the subtentacular canal by a transverse partition. At the junction of this partition with the septum of the subtentacular canal there is a passage, the septal canal, in which lies the cellular cord known as the generative tract, in connection with the visceral genital tissue. Enlargements of the rachis in the pinnules constitute the genital glands of the Crinoids, the products of which may or may not be discharged by special slits. Towards the extremity of the pinnules there is a transition between the coelom and subtentacular canals thus away, and becomes finally obsolete, thus possibly affording a means for the circulation of the nutritive fluid of the body, the subtentacular canals constituting an arterial or distributive and the coelom a venous or collective system of vessels.

From the arms the tentacular canals proceed inwards to unite with a circular canal situated around the gutlet, and having connected with it numerous short processes similar to the axis ambulacralis crani of the Ophiuridae (see page 635). There is no madreporic tubule, and the axial or madreporic canal is apparently unrepresented in the Crinoids. Reproduction seems to be effected by the tentacles, and in Comatula also by the access of water through pores in the oral portions, communicating with a series of sinuses below its under surface by means of funnel-shaped canals. The central organ of the nervous system in Asteroidea, according to Carpenter's, is the thickened dorsal portion of the axis of the stem within the corono-dorsal plate, which supplies branches to the cirri and the arms, and corresponds probably with the axial sheath which, in Pentactaria, sends off cords at the nodes of the stem into the whorls of cirri (see fig 21). A filibril band underlying the epithelial floor of the bursal funnels is regarded by Ludwig as a nerve — an afferent rather than a motor nerve (Carpenter).

The development commences with the formation from the egg of an oral morula, which secretes four loop-like ciliated bands, and a posterior terminal tuft of cilia. An endodermal sac or endoderm results from an invagination of the blastoderm between the third and fourth circular bands, and from this three diverticula, two lateral and one ventral, like their rows, the remainder of the archenteron becoming an alimentary cavity communicating with an anterior ovisac. The lateral diverticula are transformed into pericentral sacs, one on the dorsal the other on the ventral side of the alimentary cavity, when the protuberance becomes a true axis in length, there are formed two circles, each of five calcareous plates, which eventually become the oral and basal osicles of the corym. From the centre of the posterior end extends a row of eight calcareous rings, the future stem of the Crinoid, surrounding a backward prolongation of the dorsal pericentral sac. At the posterior extremity of the row is a ctenostome disk, by which the young Crinoid subsequently attaches itself. The ambulacral or the pseudotentacular system and the two lower bands of cirri disappear, and afterwards the two upper bands, and the endothen becomes fixed to a stone, a seaweed, or some other object. A new mouth is formed in the centre of the disk by the separation of the oral plates, and the intestine by the production of a diverticulum of the alimentary cavity. In the early Pentactara and stage of Comatula the basal stem rests upon the corono-dorsal segment, but becomes at length metamorphosed into a single piece, the peduncle, and the corono-dorsal segment by degrees increasing in size, the first radials come to rest upon its enfolded lip. During the same period, after the formation of an anus, the oral and basal plates disappear. The development of the basal column takes place as the prolongation of the point of the column enlarges to form the corono-dorsal plate. At the end of five or six months, when about 1 inch in diameter, the young Comatula detaches itself from its stalk, and is then able to move by means of its arms. The Pentactaria shows its form of Comatula (fig 26), previous to its discovery of the ultimate stage of its growth, had been termed by Vaughan Thompson Pentactaria euripus. The Crinoids are classed as follows:

Order 1 WEDLELLIA Canal completely formed of calcareous plates, oral face with ambulacral funnels

Family 1 TELASCITIA, Ex Centactaria, Asteroidea

Order 2 ARTICULATA Canal face of calcareous usually membranous or sub-membranous, with ambulacral funnels

Family 1 PENTACTARIA Always attached, Ex Pentactaria, Asteroidea

Family 2 COMATULIDE Attached only in the young state. Ex Astea, Phaneroia. The Cretaceous genus Merciaea appears to have been unattached.

The Crinoids are represented by Gephyroidea, Heteroecyae, Mesozoic, Tholus, Echinoidea, Phyllophora, Pachyecia, Comitaria, Pseudocomitaria, Xylocepha, Cystoceras, Echinoceras, and numerous other genera in the Paleozoic strata, where their remains, especially in the Carboniferous series, are often the chief constituents of vast masses of compact limestone. From these form the innumerable petals of the stem have come to be known as corals, echinoderms, or echinodermata, and in the north of England, as 'St Cath.
Echinodermata

Let's heads" Among the various forms by which the Crinoids were represented during the Mesozoic period, to the close of which they diminished materially in number, are Eocrinus (Maschelkalk), Eocrinus, Pedicinaria (Lias); Comatulidea (Rhynochocrinus, Eocrinus, and cephalic and posterior plates with the body-cavity. (See Billings, Ann. and Mag. of Nat. Hist. 1870, p. 259-61.)

What is usually regarded as the mouth is situated in the centre of the ventral surface of the calyx, opposite the point of attachment of the stem, and from it radiates the furrows for the arms, whence the appendages are present. It is apparently small and circular in Spheronites; in Cystoideae it is transversely elongated and lobed; in Hemicyclus elevated on a peduncle; in Echinocysta usually longitudinal and bordered by peculiar plates. A small perforation alongside the mouth, considered to be the anus, is generally present. It has sometimes, as in Echinocysta (fig. 30) and Apioctenites, the form of "an

FIG. 28.-Echinocysta arnautus. (After Forbes.)

a, mouth; b, anal aperture, and c, ovarian pyramid of the same, enlarged.

Arched or crescentic groove terminating apparently at each end with a pore, and having united with it, or placed a little below it, an orifice in the middle line of a suture, as in the junction of two oral plates" (Forbes). Almost invariably, on the oral portion of the body, interradially placed, is a round or oval aperture covered by a pyramid of 5 or 6 triangular valves. This is the opinion of most authorities as probably the ovarial orifice; but according to Mr Billings it is an oro-anal aperture, the central opening or mouth above mentioned being an "ambulacral orifice." Cystidea first occur in strata of Cambrian age. They especially characterize the Lower and Upper Silurian series of rocks, and apparently died out in the Carboniferous epoch.

Order V.—Cystidea.—The body in the Cystidea is in most cases rounded, and is covered with polygonal plates; it is attached by a stem, and may be provided with arms or pinnules developed from the upper or oral surface. The stem is short, usually similar to that of the Crinoida in construction, but without cirri; the joints are rounded, and sometimes moniliform, and usually become broader but thinner towards the base of the body. In H. Woodward, Geol. Mag. 1871, p. 71) the calyx is compressed laterally, and shows sculpturing similar to that of the plates of the pedunculated Cystidea. The plates of the calyx are pentagonal, hexagonal, or imperfectly trigonal, and are closely united together, they vary in number (1 in fig. 22) are very numerous. In Cystoideus, the calyx is composed of three rows of plates, which may be regarded as basal, parabasal, and radial. According to Prof. E. Forbes (Mem. of the Geol. Sur. of Great Britain, 1845, vol. ii. part 2), the following series of plates may be generally distinguished:—a basal series; subovarian, centro-lateral, and supra-ovarian series on a plane below, on the same plane with, and on a plane above the ovarian pyramid respectively; subovarian plates or ossicles, encircling that structure; and oral plates, immediately surrounding the mouth, which vary considerably in number (fig. 22). The plates are frequently ornamented with grooves and tubercles. Arms and pinnules are not univalve. In Comarctoidea punctata, Billings, the arms are free, sometimes nearly so; they are wanting, and the pinnules are attached to the upper portion of the calyx. Commonly the arms resemble ambulacra, and are reflected towards the base of the calyx, and closely applied to its surface. Pores on the antambulacral surface may be absent (Cystoideus), irregularly scattered (Cystoideus), in pairs (Spheronites), or, as in Pseudocrinus (2 in fig. 28), Echinocysta, and echinocysta, and other genera, slit-like, and arranged to form "nematocysts," or "hydrospheres," the two halves of each rhomb being on separate plates.

Mommaeus arnautus there are thirty pectinated rhombs, consisting each of a number of parallel internal flat tubes communicating with each other at ends with pores opening internally. The rhombs in Prionocysta are not tubular as in Cystoideus, but are made up of numerous parallel inward folds of an exceedingly thin part of the test. Again in Prionocysta tenans radiata the whole surface bears rhombs, which, when unjured, have a complete though very thin calcareous covering, and communicate by a small pore at their base with the body-cavity. (See Billings, Ann. and Mag. of Nat. Hist. 1870, p. 259-61.)

What is usually regarded as the mouth is situated in the centre of the ventral surface of the calyx, opposite the point of attachment of the stem, and from it radiates the furrows for the arms, whence the appendages are present. It is apparently small and circular in Spheronites; in Cystoideae it is transversely elongated and lobed; in Hemicyclus elevated on a peduncle; in Echinocysta usually longitudinal and bordered by peculiar plates. A small perforation alongside the mouth, considered to be the anus, is generally present. It has sometimes, as in Echinocysta (fig. 30) and Apioctenites, the form of "an

FIG. 29.—Echinocysta arnautus (After Forbes),

a, mouth; b, anal aperture, and c, ovarian pyramid of the same, enlarged.

Arched or crescentic groove terminating apparently at each end with a pore, and having united with it, or placed a little below it, an orifice in the middle line of a suture, as in the junction of two oral plates" (Forbes). Almost invariably, on the oral portion of the body, interradially placed, is a round or oval aperture covered by a pyramid of 5 or 6 triangular valves. This is the opinion of most authorities as probably the ovarial orifice; but according to Mr Billings it is an oro-anal aperture, the central opening or mouth above mentioned being an "ambulacral orifice." Cystidea first occur in strata of Cambrian age. They especially characterize the Lower and Upper Silurian series of rocks, and apparently died out in the Carboniferous epoch.

Order VI.—Edrioasterida.—Under this head are grouped such forms as Edrioaster, Agelacrinites, and Hemicystites. The shape is that of a rounded star-like or flattened echinus with a concave base. There is an ovarian pyramid, but stem and arms are wanting, and the ambulacra communicate by perforations with the calyx cavity. The Edrioasterida are exclusively Palaeozoic. Their nearest living ally is the Australian genus Hyophycus Sars, Lov., which approaches Agelacrinites in form.

Order VII.—Blastoidea.—In this group of fossil Echinoidea the bud-shaped or ovastra, arumless, and closely plated calyx is supported on a short, jointed stem. Of the three basal plates in Pentremites two are double, succeeding the basal as a row of five pieces, and into the deep cloths of the upper portion of these fit the lower ends or spaces of the ambulacra; a third series of five small, deltoid, interradial plates occupy the spaces between the oral portions of the ambulacra. The ambulacra, or "pseudambulacral areas," present a superior surface formed by a double series of ossicles running from a median line to the border, where they support pinnules; beneath the ossicles is usually a lanceolate plate formed in many if not all species of Pentremites of two contiguous plates, and edged by a single row of transverse pieces, which are pierced with marginal pores.

Each row of pores opens below into one or more flat canals, or, according to the definition of Billings (Ann. and Mag. of Nat. Hist., vol. v. 4th ser. p. 263), into a "hydrosphere" consisting of "an elongated internal sac, one side of which is attached to the inside of the shell for
test], while the side opposite, or towards the central axis of the visceral cavity, is more or less deeply folded longitudinally (see fig 32). These internal canals, as suggested by Rojo, may possibly represent the tubes under the domes of the Cnidaria. In Caloaster the ambulacra are confined to the upper portion only of the calyx. Pores and attached tubes are wanting, but there are straitened structures between the arms, similar in appearance and probably also in function to the pectinated rhombs of the Cystidea, their ridges, as first shown by Rojo (God. Mag., 1965, ii. p 231), being the tops of a series of folds of a thin test or membrane, which were perhaps "respiration sacs", lined with cilia, and constructed of a porous test, through which air from the water could pass by diffusion.

The expanded ends of the neighbouring tubes of each two ambulacra form at the summit of the test four double and two single apertures commonly termed "ovarian orifices." Between the two latter there is usually a third, apparently anal, opening. In Echylona there are three paired, and two single pores only. The Blastodones, which are (i) represented by Pentanemes in Upper Silurian strata, attained their principal development during the Carboniferous epoch, at the close of which they seem to have become extinct.

Order VIII—Holothuridea.—The Holothuridea, Sea-cucumbers, Trepsangy, or Sea-cucumbers (figs. 33 and 34) have a long, cylindrical, sometimes flattened body, which is without shell and is brown to purple-red in colour. The persons, which is unciliated, is composed of three layers,—a structureless epidermis, a cellular dermis, and an internal elastic layer. The two interior layers contain calcareous spicules, which vary much according to the species, and may take the shape of perforated disks, wheels, anchors, and hooks (fig 35). Rarely the dorsal integument may develop an armature of overlapping plates (Pedina), which may bear spines (Echinoecusus). Underlying the persons is a layer of circular muscular fibres, some of which pass into the mesenteries, a second internal set of five simple or paired bands of longitudinal muscular fibres are attached at one end to the radial pieces of the calcareous oral ring, and supply branches to the oral tentacles, and at the other are inverted into the esophagus of the anus. It is by means of the longitudinal muscles that the Holothuridae, when irritated, effects the discharge of its viscera at the hinder extremity of its body. In the midst of a circle of tentacles, five or multiples of five in number, is the mouth, which is without dental apparatus. The tentacles vary considerably in shape, and may be cylindrical, shield-shaped, conoidal, or ramified. They serve as organs of touch, of nutrition, and occasionally also of locomotion. The alimentary canal is simple, and usually longer than the body, so as to be two or three times folded on itself, it is attached to the interior surface of the body by mesenteries, and may terminate in a cloaca. Its walls are composed of an external layer of circular, and an internal layer of longitudinal muscular fibres, and an innermost cellular lining. In common with the peritoneal surface of the body, it is ciliated. Two, or more rarely four or five, branched processes of the cloaca, the respiratory tree or water-lung, are ordinarily present, and are connected to the body-wall by a mesentery or by threads (fig 36). They appear to be exertory in function, water being continually passed into and out of them through the contractile cloaca. Their ultimate ramifications terminate in minute openings, by means of which they appear to have communication with the peritoneal cavity. In Echinoecusus the respiratory tree are only single-branched. In Synapta, in which they do not occur, there are funnel-shaped ciliated bodies attached to the mesentery of the alimentary canal. The respiratory tree occupying the ventral left interradial space has been observed in many cases to be surrounded by a plexus of the pseudohemal system of vessels. What are termed Ciliarian organs, which are appendages of the cloaca, which, according to Semper (Reisen im Archiv der Philippinen, 1 pp 139, 140), are muscular, and can be used as a means of defence, being capable of protrusion externally. The main trunks of the pseudohemal system, which is often exceedingly complex, are two vessels, one on the dorsal, the other on the ventral face of the intestine, which are connected with each other by capillary reticulations. The calcareous ring surrounding the gut, already referred to,
ECHO, in Greek mythology, one of the Oreads or mountain nymphs. The word denotes mere sound; and the told stories of her are so tantalizing that they can scarcely be said to belong to the class of fully-developed myths. As Seene to the Greek was clearly an object of the speaker...
her by Hera, whom the nymph by her chatter had prevented from discovering the sports of Zeus among her sister Oreades. Another tale relates that Echo fell in love with Narcissus, who was deaf to her entreaties, and that in her grief she wasted away until nothing remained but her bones and her voice. The name Narcissus, again, denotes one who is oppressed by lethargy, and thus the story becomes a counterpart to that of Selene and Endymion. Another legend speaks of her as being loved by Pan, the Latin Favonius, the soft and purifying breeze, and represents her lover as seeking in vain to see her form, although everywhere he hears her voice—Ovid, Met. xi. 356 et seq.; Paul. ix. 31, 6.

For Echo, in physics, see Acoustics, vol. i. p. 107.

Ecki, a city of Spain, in the province of Seville, 53 miles E.N.E. of the city of that name, on the left bank of the Jenu, Xeniil, or Genil, the ancient Singulis, a tributary of the Guadalquivir. The river, thus far navigable, is 18 miles.

The principal square is surrounded with pillared porticoes, and has a fountain in the centre; and along the river bank there runs a fine promenade, planted with poplar trees and adorned with statues. From an early period the shoemakers of Ecija have been in high repute throughout Spain; and woollen cloth, flannel, linen, and silks are manufactured in the town. The vintners are a most noted hostess. Among other remarkable institutions the most remarkable is Luis Valdes de Guerriar, the dramatist. Populat. 27,216.

ECK, JOHANN MAIER VON (1486-1543), the most indefatigable and important opponent of Martin Luther, was born 15th November 1486, at Eck in Swabia. His father was a peasant, who building a mill of the village, added Eck to the family name Maier. The son entered in his eleventh year the university of Heidelberg, from which he returned to Cologne, and afterwards to Freiburg, where, besides studying jurisprudence and mathematics, he taught philosophy. In 1506 he published a work on logic. From this time he appears to have devoted his attention chiefly to theology, and his skill and versatility in scholastic disputations having attracted considerable notice, the duke of Bavaria, in 1510, presented him to the chair of theology in the university of Ingolstadt. In 1515 he took part in a public disputatio at Bologna, and in 1516 in one at Vienna, on both occasions gaining great admiration. In 1518 he circulated privately his Octaves against Luther's thesis on the mass. Luther intrusted his defence to Carlstadt, who, besides answering the main questions of Eck in 400 distinct theses, declared his readiness to meet him in a public disputation. The challenge was accepted, and the disputation took place at Leipzig in the following year. It lasted for three weeks, and Luther as well as Carlstadt opposed himself to Eck. The general impression was that victory rested with Eck; but apparently success only embittered his animosity against his opponents, for from that time his whole efforts were devoted to Luther's overthrow. He induced the universities of Cologne and Louvain to condemn the Reformer's writings, and in 1520 went to Rome to obtain strict regulations against what he called the "Lutherans." He returned with the celebrated papal bull against Luther's writings, and with the commission to publish it, but at Leipsic met with so bad a reception from the inhabitants, that he was compelled to take refuge in the Pauline convent. Eck took a leading part in the Augsburg diet of 1530, and in the conferences at Worms in 1540 and at Ratisbon in 1541. He died in 1543. He is said to have been a bad linguist, and not an able theologian, but to have possessed great readiness and facility, a retentive memory, and remarkable dexterity in sophistical argumentation. Among his numerous writings is a translation of the Bible, which was written to supersede that of Luther, but met with no success.

ECKERMANN, JOHN PETER (1732-1854), friend of Goethe, and editor of his works, was born at Wunsin in Hanover, in 1792. After serving as a volunteer in the War of Liberation (1813-1814), he obtained an appointment in the war office at Hanover. At the age of twenty-five he became a student at the gymnasium of Hanover, and afterwards at the university of Gottingen, returning to Hanover in 1825. His acquaintance with Goethe began in the following year, when he sent to him the manuscript of his "Beitrage zur Poese." Soon afterwards he went to Weimar, and was appointed private secretary to the poet. For several years he was also engaged as tutor to the son of the grand duke. In 1820 he travelled in Italy with Goethe's son. In 1838 he was named councillor of the grand duchy, and appointed librarian to the grand duchess. Eckermann is chiefly remembered for the important contributions to our knowledge of the great poet contained in his Gespräche mit Goethe, the first and second parts of which appeared in 1836, and the third in 1848. This work was first translated into English by Margaret Fuller, and published at Boston, U.S., in 1859. Another English translation, by John Ozenford, appeared in London in 1860. It has been translated into almost all the European languages, excepting Turkish. To Eckermann Goethe intrusted the publication of his posthumous works (1832-1833). He was also joint-editor with Riemer of the complete edition of Goethe's works in 40 vols. (1839-1840). Eckermann died at Weimar, December 3, 1854.

ECKERSBERG, CARL VILHELM (1783-1853), Danish painter, was born in South Jutland in 1783. He became successively the pupil of Abildgaard and of Davids. From 1810 to 1813 he lived at Paris under the direction of the latter, and then proceeded, as an independent artist, to Rome, where he worked until 1816 in close fellowship with Thorwaldsen. His paintings from this period—the Spartan Boy, Bacchus and Ariadne, and Ulysses—testify to the influence of the great sculptor over the art of Eckersberg. Returninng to Copenhagen, he found himself easily able to take the first place among the Danish painters of his time, and his portraits especially were in extreme popularity. It is claimed for Eckersberg by the native critics that "he created a Danish colour," that is to say, he was the first painter to throw off conventional tones and the pseudo-classical landscape, in exchange for the clear atmosphere and natural outlines of Danish scenery. But Denmark has no heroic landscape, and Eckersberg in losing the golden common-places scarcely succeeds in being delightful. His landscapes, however, are pure and true, while his figure-pieces he is almost as well as Carlstadt opposed himself to Eck. The general
ECKHART, JOHANNES, or, according to the general designation, Meister Eckhart, the first of the great speculative mystics, flourished during the latter part of the 13th and the early part of the 14th. Extremely little is known of his life; the date and place of his birth are equally uncertain. According to some accounts, he was a native of Strasburg, a town which he was afterwards closely connected; according to others, he was born in Saxony. Trithemius, one of the best authorities, speaks of him merely as "Thietomacus." 1260 has frequently been given as the date of his birth; it was in all probability some years earlier, for we know that he was advanced in age at the time of his death, about 1327. He appears to have entered the Dominican order, and to have acted for some time as professor at one of the colleges in Paris. His reputation for learning was very high, and in 1302 he was summoned to Rome by Boniface VIII., to assist in the controversy then being carried on with Philip of France. From Boniface he received the degree of doctor. In 1304 he became provincial of his order for Saxony, and in 1307 was vicar-general for Bohemia. In both provinces he was distinguished for his practical reforms and for his power in preaching. In what manner he ceased to hold his high office we do not know; indeed, several years of his life about this time are a complete blank. Towards 1325 we hear of him as preaching with great effect at Cologne, where he gathered round him a numerous band of followers. Before this time, and in all probability at Strasburg, where he appears to have been for some years, he had come in contact with the Beghards (q. v.) and Brethren of the Free Spirit, whose fundamental notions he may indeed be said to have systematized and expounded in the highest form to which they could attain. In 1327 the opponents of the Beghards laid hold of certain propositions contained in Eckhart's works, and he was summoned before the Inquisition at Cologne. The history of this accusation is by no means clear. Eckhart appears, however, to have been enrolled as a conditional recantation—that is, he professed to disavow whatever in his writings could be shown to be erroneous. Further appeal, perhaps at his own request, was made to the Pope, and in 1329 a bill was published condemning certain propositions extracted from Eckhart's works. But before its publication Eckhart was dead. The exact date of his death is unknown. Of his writings several of which are enumerated by Trithemius, there remain only the Sermons and a few tractates. Till recently the majority of these were attributed to Tauler, and it is only from Pfeiffer's careful edition (Deutsche Mystiker d. XVI. Jahrhunderts, vol. ii., 1857) that one has been able to gather a true idea of Eckhart's activity. From his works it is evident that he was deeply learned in all the philosophy of the time. He was a thorough Aristotelian, but by preference appears to have been drawn towards the mystical writings of the neo-Platonists and the pseudo-Dionysius. His style is unsystematic, brief, and abounding in symbolical expression. His manner of thinking is clear, calm, and logical, and he has certainly given the most complete exposition of what may be called Christian pantheism.

Eckhart has been called the first of the speculative mystics; but such a designation requires some qualification. Within the Christian church from the time of Erigena there had been a constant stream of what must be called mysticism, originating for the most part from the writings of the neo-Platonists and of Dionysius the Areopagite. This tendency may be noted in Bonaventura, in Albert (under whom Eckhart is said to have studied), and in Aquinas; it is more prominent in Hugo and Richard of St Victor, though with them it took a practical rather than a speculative direction. But in all these writers, with the partial exception of Erigena, who occupies a quite peculiar position, the mystical element was in strict subordination to some other element which might be called symbolical, but were not thereby explained or rationalized. In Eckhart's writings and preaching, on the other hand, the element of mystical speculation for the first time comes to the front as all-important. By its means the church doctrines are made intelligible to the many, and from it their true significance is derived; it is natural that he should gradually diverge more and more widely from the traditional doctrine, so that at length the relation between his teaching and that of the church appeared to be one of opposition rather than of reconciliation. Eckhart is thus in truth the first who attempted with perfect freedom and logical consistency to give a speculative basis to religious doctrines.

It is not possible to expound in detail how Eckhart endeavours to explain the main principles of the Christian faith, but it is necessary to note the two most important points in his as in all mystical theories. First, his doctrine of the divine nature, and second, his explanation of the relation between God and human thought. The two are logically connected, and a complete exposition of his theory might start from either his theology or his psychology. Lasson, the author of a most valuable monograph on Eckhart, adopts the latter course, but for many reasons the other appears the most systematic.

The fundamental thought from which Eckhart's theology starts is that of the Absolute or Abstract Unity as the only real existence. Apart from God no thing has real being. But this Absolute is, for Eckhart, the Deus absconditus, the 5Sar Eyneousc of the neo-Platonic theology. With Dionysius the Areopagite, Eckhart describes this divine essence, the Godhead, as absolutely without predicates, all determinations are limitations which destroy its infinite being. The Godhead is incomprehensible, inexpresable. It is in truth nothing; yet as the most real of beings it must be conceived as absolutely potential, as containing in itself the origin and final end of all things. This Godhead is not God as known to us. From the Godhead the triune God proceeds or is evolved. At this point, at this transition between the divine Absolute and the personal deity, Eckhart is face to face with the crucial difficulty of all speculative mysticism, and it is of interest to compare his method of solution with that adopted by later thinkers of like tendencies, e.g., Boehme and Basler. In the Godhead, as in everything, according to Eckhart, there must be distinguished matter and form, or, as they are more usually called, essence and nature. The potentiality, what the thing is in itself; the form or nature is that which it becomes as an object for others. The Godhead reveals itself in the personal God, the Father, as the spiritual substance, and as such can only become real by consciousness, by reflection on self, by self-expression. That which reflects is the Son in the Father. The Father is the power through and in which the Father becomes self-conscious. As there is here no distinction of time or space, Father and Son are in very truth one. The Father eternally begets the Son, and the return of the Son into the Father in love and mutual will is the Spirit. The Father is not before the Son; only through the begetting of the Son, only through arriving at self-consciousness, does he become the Father.

The genesis of the Son from the Father involves also, according to Eckhart, the production of the world of things. For God is reason, and in reason is contained the ideal world, the world of creatures, not in time and space, which becomes materialized. In materialization all things are made, but not in time and space, and it is in time and space that it takes form and form, in ideal form. He holds strongly to the so-called Platonic view that, over and above sensible things, there exists a realm of ideal forms or exemplars, to be apprehended by pure thought, through thought freed from the limitations of space and time. How this ideal world is related to the world of real things he does not show, nor does he explain the apparent independence of the material universe. When, therefore, Eckhart speaks of the world as necessary to the divine existence, of God as loving Himself in created things, and of all things being integrated into the infinite universe, he is understood to speak of an ideal world, not of things as known to us.

As all things have arisen from God, so all things desire to return into the unity of the divine. In the Son, the power of the ineffable cognition, the power of creating and being created, is to be found, and in the Son is the power of returning to the Father. In man, the noblest of created things, this return is brought about. In man, specially, there is the faculty of supersensible cogitation, the power of comprehending the ground of both God and of the universe. This peculiar power, called
by Eckhart the spark (Punkleus, Scintilla), is in truth God working in man. In cognition of God, God and man are one; there is no distinction of knower and known, and hence, as opposed to empirical knowledge, it is called faith. In each case, there is an internal, not only an external, reason, but will, for the divine illumination becomes operative or takes real effect through the will.

To attain to full union with God is the final end of activity, and the means, it is clear, must be the renunciation of all individuality. And hence it appears to be the only method whereby the birth of the Son in the soul may be brought about. When this state has been reached, then the human soul is one with God; its will is God's; no evil can be wrought by it, it cannot sin. The practical consequences which would follow from such a doctrine, and which did appear among the Brethren of the Free Spirit, were evaded, rather than overcome, by Eckhart. For, according to his teaching, all the above applies only to the "spark" in the soul; the other faculties may be reasonably and legitimately employed about other and temporal matters. By this grade, also, he escapes the doctrines that works are entirely insufficient. He is careful to hold the balance between inward feeling and outward action, and on this point his teaching is important in relation to the later Reformation thinkers.

On the specifically theological doctrines of Eckhart, such as Grace, Incarnation, the Fall, Redemption and Sin, it is not possible to enter in brief compass. A most adequate account of them will be found in lapidary paragraphs elsewhere referred to.

The most important of the many works upon Eckhart are: Piëler, Deutche Eckhel, vol. ii. (Hamburg, 1833); Eckhel, Deutscher Vierteljahresschrift, 1864; Johanns, Revisser der Deutschen Philologie, 1736; Gluck, Geschichte d. Deutschen Mystik, 1737

ECKHEL, JOSEPH HILARIUS (1737-1798), one of the most distinguished numismatists, was born at Enzersfeld in Lower Austria, January 13, 1737. His father was farm-steward to Count Zinzendorf, and he received his early education at the Jesuit's College, Vienna. Here at the age of fourteen he was admitted into the order, still pursuing his studies with earnestness, and especially devoting himself to antiquities and numismatics. After being engaged as professor of poetry and rhetoric, first at Steyer and afterwards at Vienna, he was appointed in 1772 keeper of the cabinet of coins at the Jesuit's College, and in the same year he went to Italy for the purpose of personal inspection and study of antiquities and coins. At Florence he was employed to arrange the collection of the grand duke of Tuscany; and the first fruits of his study of this and other collections appeared in his Numeri Vetera Aedificati, published in 1775. On the dissolution of the order of Jesuits in 1773, Eckhel was appointed by the empress Maria Theresa professor of antiquities and numismatics at the university of Vienna, and this post he held for twenty-four years. He was in the following year made keeper of the imperial cabinet of coins, and in 1779 appeared his Catalogus Viadobonensis Numorum Veteran. Eckhel's great work is the Numeris Veterum, in 8 vol. in folio, which was published in 1792, and the last in 1798. The author's rich learning, comprehensive grasp of his subject, admirable order and precision of statement in this master-piece draw from Heyne enthusiastic praise, and the acknowledgment that Eckhel, as the Cyprius of numismatists, had, out of the mass of previously loose and confused facts, constituted a true science. A volume of Adhenda, prepared by Steinbuchel from Eckhel's papers after his death, was published in 1826. Among the other works of this great scolar are: Chaus de Piéregrave du Cabinet Imperial de France, a useful school-book, a work entitled Kurzezüge Anfangsgrunde von alien Numismatik (1787), of which a French version enlarged by Jacob appeared in 1825, &c. Eckhel died at Vienna, May 16, 1798.

ECCLECTIC (from ἐκλάω, to select), a term of which the meaning is in philosophy, denotes a thinker whose views are borrowed partly from one, partly from another, of his predecessors. It perhaps requires to be noted that, where the characteristic doctrines of a philosophy are not thus merely adopted, but are the modified products of a blending of the systems from which it takes its rise, the philosophy is not properly eclectic.

The history both of ancient and of modern eclecticism shows that eclecticism naturally springs up when, while pure literary culture makes the doctrines of the chief philosophers familiar and preserves an interest in philosophy, the first pursuit of thinkers is not purely speculative truth.

In the 2d century a. d., a remarkable tendency toward eclecticism began to manifest itself. The longing to arrive at the one explanation of all things which had inspired the older philosophers became less earnest, the belief, indeed, that any such explanation was attainable began to fail, and thus men, not feeling the need of one complete logical system, came to adopt from all systems the doctrines which best pleased them. In Panaitius we find one of the earliest examples of the modification of Stoicism by the eclectic spirit; and about the same time the same spirit displayed itself among the Peripatetics.

The philosophy that took root in Rome, where philosophy never became other than a secondary pursuit, was naturally for the most part eclectic; of this Cicero is the most striking illustration,—his philosophical works consisting of a mixture, with little or no blending, of doctrines borrowed from Stoicism, Peripatetics, and the scepticism of the Middle Academy. And, not to mention numerous names of minor importance, eclecticism had another representative at Rome in the school of Sextus and Sotion, who were half Stoic, half Pythagorean.

In the last stage of Greek philosophy the eclectic spirit produced remarkable results outside the philosophies of those properly called eclectics. Thinkers chose their doctrines from many sources,—from the venerated teaching of Aristotle and Plato, from that of the Pythagoreans and of the Stoics, from the old Greek mythology, and from the Jewish and other Oriental systems. Yet, it must be observed that neo-Platonism, Gnosticism, and the other systems which are grouped under the name Alexandrian, were not truly eclectic, consisting, as they did, not of a mere syncretism of Greek and Oriental thought, but of a mutual modification of the two. It is true that several of the neo-Platonists professed to accept all the teaching both of Plato and of Aristotle, but, in fact, they arbitrarily interpreted Aristotle so as to make him agree with Plato, and Plato so as to make his teachings consistent with the Christian systems which they had adopted, and the same manner as the schools attempted to reconcile Aristotle with the doctrines of the church. Among the early Christians, Clement of Alexandria, Origen, and Simeon were eclectics in philosophy.

The eclecticism of modern philosophy are too numerous to name. Of Italian philosophers the eclectics form a large proportion. Among the German may mention (though details cannot here be given) Wolff and his followers, as well as Mendelssohn, Eberhard, Plumer, and to some extent Schelling, whom, however, it would be incorrect to describe as merely an eclectic. In the first place he cannot be denied the praise of originality; and, in the second place, it is not so much that his views of any time were borrowed from a number of philosophers, as that his thinking was influenced first by one philosopher then another.

But, during the present century, the term eclectic has come to be specially applied to a number of French philosophers who differ considerably from one another. Of these the earliest was Royer-Collard, who was mainly a follower of Reid, and Mauro de Bure; but the name is still more appropriately given to the school of which the most distinguished members are Victor Cousin, Théodore Joubert, Daurac, St Hilaire, Esmant, Garner, and Ravaisson. Cousin, whose views varied considerably at different periods of his life, not only adopted freely what pleased him in the doctrines of Leibnitz, Royer-Collard, and Mauro de Bure, of Kant, Schelling, and Hegel, and of

the ancient philosophies, but expressly maintained that the
eclectic is the only method now open to the philosophic,
whose function it is to observe into a critical selection and
nothing more. "Each system," he asserted, "is not false,
but incomplete, and in uniting all incomplete systems, we
should have a complete philosophy, adequate to the
totality of consciousness." But this assumes that every
philosophical truth is contained somewhere in the various
philosophies; and if this were surely rash to deny, there
is no doubt that philosophical truth undiscovered, but dis-
covered by human intelligence, it is evident that eclecti-
cism is not yet the only philosophy. For a discussion of
the question how far the above dicta of Cousin represent
his own method of philosophizing we must refer the reader
to the article Cousin. Eclecticism gained popularity,
and, partly owing to Cousin's position as minister of public
instruction, became the authorized system in the chief seats
of learning in France, where it has given a most remark-
able impulse to the study of the history of philosophy.

ECLIPSE. See ASTRONOMY.

ECSTASY (ἐκστασις, from ἐκστασθω, to put out of
its place, to alter), a term applied to a morbid mental condition,
in which the mind is entirely absorbed in the contemplation
of one dominant idea or object, and loses for the time its
normal self-control. With this there is commonly associ-
ated the prevalence of some strong emotion, which manifests
itself in various ways, and with varying degrees of intensity.
This state resembles in many points that of catalepsy
already described, but differs from it sufficiently to consti-
tute it a separate affection. The patient in ecstacy may lie
in a fixed position like the cataleptic, apparently quite un-
conscious, yet, on awaking, there is a distinct recollection
of visions perceived during this period. More frequently
there is violent emotional excitement, which may find ex-
pression in impassioned utterances, and in extravagant
bodily movements and gesticulations. This disease
usually presents itself as a kind of temporary religious in-
sanity, and has frequently appeared as an epidemic. It is
well illustrated in the celebrated examples of the dancing
epidemics of Germany and Italy in the Middle Ages, and
the Conulsioniawres of St Medieval at the grave of the Abbé
Paras in the early part of the last century, and in more re-
cent times has been witnessed during periods of religious
excitement in this country. This disorder is highly
tortuous, and readily spreads by imitation. As a disease
it is more curious than important, and for its treatment
requires the judicious exercise of moral influences rather
than medical remedies, although these also, as in the case
of similar ailments, may often be used with advantage.

ECUADOR, or, in full, LA REPUBLICA DEL ECUADOR, an
independent state of South America, traversed by the
equator, from which it takes its name, and bounded on the
N. by the United States of Colombia, E. by Brazil, S. by
Peru, and W. by the Pacific Ocean (see plate xi. vol.
1.). Its area cannot be stated with any close approxima-
tion to accuracy, for large districts along the frontiers are
equally claimed by Ecuador and the neighbouring powers;
and even within the limits of undisputed possession no
systematic survey has been undertaken. According to
Villavicencio, the area is only 127,205 Spanish square miles;
but P. Hanemann, quoted by Behm and Wagner (Bevolk-
erung der Erde, 1874, p. 76), makes it 248,330 by plani-
metric calculation on the basis of H. Kiepert's map in his
Handlungs, 1872, Kiepert places the eastern limit at 70°
W. of Greenwich, but does not assign to Ecuador the dis-
puted territory along both sides of the Marañon. The
population was stated by Villavicencio at 1,108,862 in 1857,
exclusive of about 200,000 wild "Indians," but an official
estimate for the same year is quoted by Wappaus, which gives
only 881,943, exclusive of 150,000 "wild" Indians, and
even this he thinks is probably too high. His opinion is
so far confirmed by the memoir of the minister Leon, published
in 1874 and 1875, according to which the total population, exclusive of about 200,000 Indians, was 866,137. The
Galapagos Islands, an unhabited group with an area of
2551 square miles, are dependent on Ecuador.

Mountains.—The great South American chain of the
Andes traverses Ecuador from south to north, and forms the
predominant factor in its physical constitution. Its twO
Cordilleras run parallel with each other, and incline an
elevated longitudinal valley about 40 miles wide and 300
miles long, which is divided by the transverse ridges, or
nudos, of Tipulpo and Ayausa into the three great basins
of Quito, Ambato, and Cuenca, which are again subdivided
by inferior ridges into irregular sections. The eastern
Cordilleras attain in several of its summits a height of
more than 18,000 feet; the western has only one (Chim-
borazo) which exceeds 17,500. The Quito plain lies 9500
feet above the sea, Ambato 5500, and Cuenca 7800: the
last two are comparatively narrow and melancholy, while
the first, though so much the loftiest of the three, is clothed
with luxuriant vegetation. The altitude of the Tipulpo or
Chinacche ridge, stretching across from Cotopaxi to Huiiza,
is 11,500, and that of the Ayausa ridge about 13,500.
Both the western and eastern slopes of the chain are marked
by magnificent valleys of erosion; the former, which con-
tains at least six successive terraces, has an average gradient
of 275 feet per mile, while that of the latter is only 125.
Granitic, gneissoid, and schistose rocks are the main
materials of the gigantic pile; the summits are capped
with trachyte and porphyry, and the sides are strewn with
dense beds of grava and volcanic debris. Thus, in the
whole Andean system do the individual mountains attain
so magnificent a development as in the Ecuadorian
section. Around the valley of Quito alone there are twenty
noble volcanic summits, presenting a beautiful variety of
form,—here a perfect and there a truncated cone, there
a jagged and blasted crest, and there again a smooth and
snow-covered dome.

In the Eastern Cordilleras the following are capped with perpetual
snow—Cayamb, Antisana, Cotopaxi, Llanganati, Sincolagou,
Sungu, Sana-turco, Tunguragua, Colinas, and Ayaus: in the
region between Chimborazo, Illiniza, the Galapagous group,
Corazon, Atacazo, Chiles, Caraburua, Yana-turco, and Quitunda.
Imbabura may either be assigned to the eastern range, or, perhaps,
more properly regarded as the common point of the two
mountains. At the northern end of the great central valley, attains
a height of 19,029 feet, and is remarkable for its vast eruptions of mud
and water, the most extensive of which took place in 1861. This
name, equivalent to the "fish-producing," from sima, fish, and bura,
mother, is supposed to refer to the quantities of Pseudodides cyclopium
said to have been contained in its discharges—a phenomenon, how-
ever, which has been called in question by Wagner, after a search-
ing investigation into the origin of the report. Cayamb (or by
mistake, Cayambo) is situated exactly on the equator, and is thus
distinguished, as Humboldt observes, from every other snow-capped
mountain in the world. It is the loftiest summit in the eastern
Cordilleras, and spreads out at the base over a very extensive area.
Antisana rises with a double dome to the height of 18,880 feet,
and presents the proof of its former activity in its magnificent
terraces, of which one, according to Wagner, is 180 feet
long, and five hundred feet deep. It may now be clasmed with the
apogean, though Humboldt saw smoke issuing in 1802. On the
side of the famous tomas of Antisana at a height of 13,300 feet
above the sea. To the next two peaks—Sincolagou and Rumi-
huay, respectively 16,360 and 16,083 feet in height—comparatively
little attention has been paid, perhaps from the rivalry of their
southern neighbour Cotopaxi. This magnificent mountain has
already been briefly described (vol. vi. p. 460). It is the loftiest
volcano in the world. The apogean is 29°, according to Wagner 29°, the north-western side being very
slightly steeper than the south-eastern. The spacial angle is
12° 20'. On the east it is covered with snow, but it is usually kept bare by the action of the trade winds. Its crater,
estimated by Wagner as less than that of Mount Etna, is bordered
and banded of trachytic rock, forming a huge caldera, white.
On the southern slope, at a height of 15,059 feet, a small
C E U A D O R  645

cene of periphyttne andlits, called el Panche, the beak, or Clubes del Inca, the Inca's head, lefts its bare cliffs for above a thousand feet, and from its general appearance gives some show of reason to suppose that it is still much regarded as the most perfect summit of the mountain blown off at the first eruption in 1522. The present summit is a cone-shaped cloud, and even in the cleanest mouth of the year it becomes invisible only for eight or ten days. "The Taucunga plateaus," says Wagner (Neu Reisen im trop. Amerika, p. 514), "the height of 30,000 feet is the prevailing direction of the wind is mendosal, usually from the south in the morning, and frequently from the north in the evening, but over the summit of Cotopaxi, at a height of 18,000 feet, the north-west wind always prevails throughout the day. The gradually-widening volcanic cloud continually takes a south-eastern direction over the rim of the crater, at a height however, about 21,000 feet, it suddenly turns to the north-west, and maintains that direction till it reaches a height of at least 28,000 feet. There are thus from the foot of the volcano to the highest point attended by its smoke-cloud three quite distinct regular currents of wind." The principal product of the Cotopaxi eruptions is pumice-stone; and the flanks of the mountain are covered with deep beds of this material mangled with trachyty rocks. In the vicinity fragments of obsidian are common in great profusion. Llanganati and Cerro Hermoso have been little visited except by natives in search of the golden treasures of the Incas believed to be hid in one of its lakes; and even their curiosity was quenched by the mysterious fate of Pastron Longa. Its height is 17,483 feet, and it is said by Villacceo to contain large quantities of pyrites. In regularity of structure the cone-shaped summit of Tunguragua is similar to Cotopaxi, but attains an altitude of 17,663 feet above the Pacific. It is, and, as much as it rises directly from a plain only 5700 feet above the sea, has the appearance of being much more ancient, or in an earlier stage of its activity than from the structure of the latter, the mountain. Cotopaxi, from its heart-shaped appearance, is equally destined to a crater. So much so, that Wagner, in 1844, the Cordillera only 6000 feet above it, reached the summit, 18,700 feet, and observed that smoke was emitted, accompanied by a catalastic fed by the snows on the cone. Its summit, 17,395 feet above the sea, is the culminating point of the Andes. The "Mountain of the volcano," as Humboldt, a height of 21,420 feet, and long regarded as the culminating point of the Andes. The fact that it only makes the ascent of the "Mountain of the volcano," as Humboldt, a height of 21,420 feet, and long regarded as the culminating point of the Andes. place by several distinct mouths. For some distance beyond the mouth of the Coca the channel is navigable for steam-boats, and the natives proceed in canoes as far as the Catacan del Canda, 5393 feet above the sea-level. The Coca, which descends from the Pimampiro Cordillera in the northern limits of the country, has a course of about 420 miles. The Coca, rising in the neighbourhood of Cayambe and the Guaman Mountains, receives the Maspa and the Cosanga, flows eastward along the line of the equator as far as 78° 10' W. long, turns southward, takes a leap of 137 feet, and maintains the same direction till it reaches the Napo rather as a rival than a tributary. The Napo system thus drains a district extending from 1° N. to 3° S. lat. and from 78° 10' to 73° 50' W. long. The only other Ecuadorian tributary of the Amazon that has any claim to special notice is the Pastaza. Instead of having its head-waters in the eastern slopes of the Eastern Cordillera, as is the case with most if not all of the rivers already described, it rises in the central plateau, within the shadow of Cotopaxi, forces its way through the range to the north of Tunguragua, and flows south-eastwards past the roots of Sangi, augmented from stage to stage by the numerous torrents that are fed by the eternal snows. It bears the name of Patate till its junction with the Chambon in the neighbourhood of Baños, and is not recognized as the Pastaza above the Agoyan falls. As early as 1741 it was navigated without difficulty by Don Pedro Malundado; and it is believed that it would afford a passage for steam-boats for a distance of 314 miles. Mr. Simson, one of the most recent explorers of eastern Ecuador, gives a graphic account of the terrific floods to which its mountain tributaries, and more especially the Topo, are subject. The rise of the waters is sometimes sudden, and their fury so irresistible, that trading parties are imprisoned for weeks in the narrow strip of land between one torrent and the next; and the whole country is traversed in the line of the currents by long ridges, or esquillas, produced by the disintegration and removal of all the intermediate tracts. The same, indeed, holds true more or less of the whole eastern slope of the mountains and of the upper sections of all the rivers. On the western versant of the Ecuadorian Andes there are three river systems of considerable size—the Mira, the Esmeraldas, and the Guayasquil. The first has its head-waters—the Rio Blanco, the Pisco, and the Punta—of the province of Ilindisu, breaks through the Western Cordillera, receives from the left the San Pedro, Paramua, Cachiayacu, Chachavi, Canumbi, and from the right the San Juan, Guapi, and Nuple, and empties itself by several mouths into the Pacific near the island of Tumaco. The second, which is the largest of the three, collects its abundant waters from Cotopaxi and Sincholagua, the transverse ridge of Tiupulo or Chisnécho, Ilindisu, Pichincha, and Cayambe. The Cotopaxi tributary, known as the Rio Pecu, forms three beautiful cascades, the highest of which is about 220 feet. To the Guayasquil system belong the Daule, the Babahoyo, and the Yaguarcocha, with their numerous tributaries,—the Daule rising in the Sandono ridge, the Babahoyo in the slopes of the Western Cordillera, and the Yaguarcocha in the skirts of Chimborazo. They are all navigable for some distance inland by steamer, and are of great importance in connection with the transport of native produce to the port of Guayasquil. Floods are usual in the rainy seasons, and vast areas are laid under water. In the Daule the tide is felt at Cayalalara, 25 miles inland. Along the coast, between the mouth of the Esmeraldas and the Gulf of Guayasquil, a large number of streams find their way to the sea; but as they all have their sources in the comparatively insignificant line of hills that runs north and south about 25 or 30 miles inland, they are themselves comparatively insignificant.

Lakes.—While Ecuador can boast of nothing worthy of the name of an inland sea, it possesses a large number of lakes, either lying in the Iaps and extinct craters of the Andes, or formed in the lowlands by the overflow of its rivers. To the former class belong San Pablo, at the foot of Imbabura, 5 miles in circumference; Cuy-cochas, on the south-east skirt of Cotocachi, 10,200 feet above the sea, and thus one of the highest lakes in the world; Yaguar-cochas, or “Lake of Blood” not far from Ibarra; Queros, about 4600 feet in diameter; Colea, to the east of Riobamba, with a powerful whirlpool in the centre; and Colay, to the south of Riobamba, which exhales gases poisonous enough to stupefy the birds that attempt to cross, and thus helps to fill the larder of the Indians in its neighbourhood. The largest specimens of the second class lie along the Napo. Thermal springs are mentioned in numerous localities,—as at Blerenco and San Pedro del Tingo, north-east of Quito; at Cachilacta, in the district of Nanegal; in the skirts of Ruminahui; at Timbuctuyopyo, near Tacuna; on the slopes of Chimborazo; and at Balos, near the foot of Tunguragua.

Minerals.—Ecuador is less rich in minerals, especially in the precious metals, than any other of the South American states. Silver, gold, iron, mercury, lead, tin, zinc, copper, antimony, manganese, alum, sulphur, and salt are all said to be found; but very few of these exist in sufficient quantity to affect the destinies of national industry. Gold mixed with silver has long been obtained in the neighbourhood of Zaruma, in the province of Loja, and it is gathered by the Indians from the river beds in the Napo and Canosol territory, and more particularly from the Bobonaza. The gold of the Canelos is about 23 carats fine, and that of the Napo 20. The town of Azogues derives its name from its prolific quicksilver mines; and similar deposits are worked within the city of Loja. In the pueblo of Simiatug, to the south-east of Riobamba, the natives manufacture sal from brine springs, and export it under the name of sal de Tavamora; the producer of Salinas—a name which tells its own tale—in Imbabura, finds its way along the Napo. Coal of good quality occurs in the province of Cuenca and also on the banks of the Napo near Pucarú, the “Red Mountain." Marble, alabaster, gypsum, slate, and other industrial rocks are obtained in various localities; beautiful rock crystal is worked at Chongon, in the province of Guayaquil; and in the coast districts there exist considerable deposits of asphalt.

Climate.—The description already given of the position and vertical arrangement of the country implies the main characteristics of Ecuadorian climate. The snow-line varies considerably in the different seasons of the year, as well as according to the form and situation of the individual mountain. Wagner found it in May on Cotocachi, 15,788 feet high; on Guaynas-Pichincha in June, 15,741; on Mroz-Pichincha in May, 15,762; on Ilindisu in December, 15,494; on Carahuirazo in January, 15,888; on Tunguragua in February, 15,914; and on El-Altar in February, 15,654. The greatest difference, according to his observations, existed between the south side of Cotopaxi (15,279 feet) and the north side of Chimborazo (15,914). This elevation of the snow-line—so great when compared with its European position—of course renders possible the existence of vegetable and animal life at a correspondingly great height. While St. Bernard’s, the highest point of permanent human habitation in Europe, is only 8377 feet above the sea, most
of the towns and villages of the central plateaux from Ibarra to Cuenca lie between 8500 and 9500 feet, many of the huts of the cattlemen are at a height of from 11,500 to 12,800; and the loftiest of these, at Cumayaco, on the north side of Chimborazo, in 1° 29' S. lat., stands no less than 13,396 above the sea. The temperature of these upland districts is of course comparatively low. "At Quito," says Professor Orton, "it is neither spring, summer, or autumn, but each day 18 a transitional position of the country is the main factor, and accordingly at Guayaquil we find the thermometric mean is 98°, the range in the 24 hours about 10°, the annual maximum 70°, and the annual minimum 45°. In the lower coast regions the tropical position of the country is the main factor, and accordingly at Guayaquil we find the thermometric mean is 98°, and during the rainy season the oppressive and pestiferous air "reminds the geologist of the steamy atmosphere of the Carboniferous period." The rainy season, or invierno, in Ecuador continues from December to May, with a short period of dry weather called the veranillo shortly after the December solstice. The rest of the year forms the sereno, or summer, which, however, is in like manner interrupted by a little rainy season called the esternilla, or CordHZno de San Francisco, after the September equinox. The mean annual rainfall at Quito is 70 inches. In the coast region the two seasons are not very distinctly marked - in the invierno the sky is sometimes perfectly cloudless, while during the veranillo there occasionally falls a continuous drizzle called garua According to Villavicencio, a gradual diminution of rain has been observed in this district of irregular seasons, and he predicts the assimilation of its climate to that of the rainless coasts of Peru. On the eastern side of the Andes, on the other hand, rain occurs almost at any time of the year, and almost every morning the woods are watered by the gentle showers of the rocita. During the veranillo the Cordilleras and montes are visited by violent hailstorms, and winds of almost incredible force sweep across the winter scene. In its relation to human health the climate of the upland region is interesting. Goitre is common; and it is found necessary to maintain three large hospitals for lepers. Tubercular disease of the lungs, on the contrary, is said to be completely unknown 8000 feet above the sea, while it is one of the most frequent of diseases in the coast districts of Tropical America. The effects on the human organism of the ascension of the loftier summits are very variously described, owing doubtless to individual differences of constitution. One thing seems established, - that the pugnacious instinct of both men and the lower animals is greatly weakened.

**Botany.** - The flora of the Quitoan plateau has been well explored by various European botanists, and more especially by Dr. Jameson of the university of Quito, that of the western slopes and lowlands is less perfectly ascertained; and that of the rough-wooded country stretching eastward from the Andes is still in great part undescribed. From the coast of the Pacific upwards to a height of about 3000 or 4000 feet, the vegetation is distinctively tropical, including among its economical species the banana, the sweet potato, rice, maize, the bread-fruit tree, mulgo, cotton, cocoa, the yam, the mandio, and the sugar cane. Most of these become rare above 3000 feet, but a few, like the sugar cane, are cultivated as high as 8000. Few parts of the world can vie in richness of vegetation with the alluvial valley of Guayaquil, which in the matter of fruit trees alone produces plátanos, pomegranates, shaddock, oranges, lemons, apricots, charimoyas, pultas, granadillas, tunas, mangoes, pacaes, and many others of less importance. Between 6000 and 10,000 feet above the sea the European cereals are successfully cultivated, along with the chick-pea, the broad-bean, the cabbage, the guinea (Chenopodium Quinoa), potatoes, Oryza, Bauhinia, and Pouteria. Wheat will not form the ear lower than at 4500 feet, or ripen higher than at 10,500; but barley and rye can be grown at a still greater elevation. The oak, the elm, the ash, and the beech never descend lower than to 5500 feet, and are seldom found higher than 2200. Further up, the larger forest trees, except the pine, begin to disappear; but the *Exallonea myrtaformis* is met with at an elevation of 13,000; and the shrubby *Esparus* ascend 400 or 500 feet higher. In the treeless region that lies between 11,600 and 13,500, or in other places between 12,000 and 14,000 feet, the similarity of the vegetation of that of the corresponding European region is, according to Wagner, especially striking. In the paramos of Chimborazo, Pichinchas, Imbaza, &c., the relation of characteristic genera to those identical with genera in the Alpines flora of Europe is as 5 to 4, and the botanist might almost suppose himself in the Upper Engadine. As the region of cryptogams does not properly begin till about 17,000 feet on Cayambi and Chimborazo, most of the summits of the Cordilleras, failing, as they do, to reach this elevation, yield a considerable harvest of phanerogamous plants. Bousangault discovered a species of *Saxifraga* (Saxifraga Bousangaulti) at a height of nearly 16,000 feet on Chimborazo, and Wagner found the trachytic rocks of Pichinchas, Imbaza, and other peaks, far above the snow-line, covered in many places with the gonda-plant, or *Oleostium nudale*, *II*. The species in those upper regions are frequently very remarkable, and a large number of strangely-modified forms have been collected from the crater's of the volcanoes.

In its forest lands alone Ecuador possesses almost insatiable resources. Seven different species of cinchona are known to exist within its borders, the *Ceroxylon andricus* and many lesser species of palm abound on both sides of the Cordilleras; and redwood, Brazil wood, palo de cruz, guanacu or holy wood, ebony, cedar, and aguana are a few of the more usual timber trees. In the dripping forests of the west grows the sumis-caspi, which forms excellent fuel even in its moistest condition. Copal, dragon's blood, India-rubber, storax, and several valuable dye-stuffs are obtained from indigenous plants. The cabuya or agave, the *San Jose palm*, *II*, yield textile fibres; and the leaves of the *Alhakan* plant (*Corallodona palmata*) and the *mocora*, a cocoa-nut-like tree, furnish material for the well-known hats.

**Zooloy.** - The fauna of Ecuador does not present a great variety among the mammals; but the birds, and still more the insects, are very numerous. The jaguar, the puma, the ounce, and the ocelot are the chief representatives of the cat tribe, monkeys of various species are common; the four characteristic animals of the Andean range, the llama, the guanaco, the vicuna, and the alpaca, are fairly abundant; large birds and flocks of European cattle and sheep are found in the rich pasture of the paramos, and horses, asses, and mules are reared in sufficient numbers to be articles of export. Few rivers are more densely peopled with alligators than the Guayayquil and Esmeraldas; and several of the largest species of snakes are natives of the warmer regions of the country, though in the Cordilleras and plateaux the reptilia are very rare. The condor, the turkey buzzard, the gallinazo, the crane, and the pelican are among the larger birds; and ducks, pheasants, and partridges are not uncommon. Of the lesser birds perhaps none appears in such number and such striking variety of form and colour as the humming bird, which is found frequently at a great height on the mountains. The flaxer or flute-bird is especially noticeable for the artistic character of his song. That the entomologist finds a rich harvest of coleopterous insects in the low countries is in keeping.

---

1 See his *Sympbron Plantarum Equatorianorum*, 2 vols.
with what might be expected; butterflies are so numerous in some parts as even to surpass the veteran collector; and in certain favoured regions, mosquitoes, sand-flies, and the equally troublesome pumas scourge as prolific as their ancient congeners in Egypt. The silk-worm has been successfully introduced, but bee-keeping is as yet practically unknown. The ethnology of Ecuador, and more particularly that of the rivers of the Amazon system, is very partially ascertained; but the species of the two vespers seem to be quite distinct. According to Wagner's investigations the distribution is mainly vertical, and to the N. of Chumborazo alpine forms go as high as 15,400 Paris feet; the forms of the lower region (or under 1000 feet), are closely connected with those of Brazil and Guiana; more peculiar genera appear in the middle region (from 1000 to 7700 feet), and the upper region is exclusively occupied by characteristic and frequently very strangely-shaped genera; the number of species is comparatively small, and that of individuals great only in the lower parts of the rivers.

Produce and Industries. — The finest article of foreign export is cotton, of which two kinds are especially distinguished in the market—the fine "up-river" quality and the so-called Machala quality. Spain is the greatest purchaser, then England, Germany, and Peru and Chili. In 1874 the total quantity that left the country was 440,091 Th., valued at 2,752,361 pesos, or, taking the peso as equal to 4s. 2d., £573,412. The collection of income-tax, 67,451; duty on sale of land, 216,110; rice, 19,744 pieces, at 88,848 pesos; dried skins to the amount 312,785, gunpowder monopoly, 57,000; stamps, 91,200; tithes, 91,200; and numerous others. In 1877 the national debt amounted to 16,970,968 piastres (or £457,724), of which £1,242,000 was the English loan stock in 1865.

Artificial means of communication are still for the most part primitive; a very few wagons convey, though no countries have canals, so little reason to be content with their natural highways by land or water. Many of the roads, even between important centres of population, are mere mule-tracks, a little improved by the weather it may be for weeks or months at a time; while the violent torrents which have so frequently to be crossed often present something better than more than one bridge to the question or amurp of the Kamshans. The simplest of these is the faruwa, consisting of a single tight rope, with or without a travelling rope by which the passenger or his luggage may be hauled across; the most complex is the chiims-chaon, a rude prototype of the regular suspension bridge, constructed of four or five ropes of apeco-root fibre, supporting transverse layers of bamboo. The best are hazardous to all except a practised foot, and they go out of repair in a few years. Since the middle of the century something has been done to improve this state of affairs; and a very great deal more has always been about to be done. According to Moreno's address to congress in 1876, Ecuador had at that time 90 miles of railway, nearly 200 miles of cart-road with substantial bridges, and about 250 miles of roads fit for the ordinary mule-traffic of the country. The total length of the constructors is exclusively occupied by the inland districts, the transport of goods of every description being effected by porters or mules. The first carriage was introduced into Quito in 1866, and the owner had to pay tax for his innovation.

With the partial exception of such rude forms of relief as still linger over the semi-civilised Indians, the only religious body is the Roman Catholic. Nowhere in modern times have Jesus and priests had more their own way. Even in 1876 Dr Borrero said "the influence of the Church is still paramount, and it is expedient to declare that he would protect the religion of his fathers, which he believed had not an enemy in all Ecuador." Two years before, in spite of the extremely depressed state of the finances, ten per cent. of the part of the church revenue belonging to the state was assigned to the Pope as an annual offering. The oath of a Protestant has no value in the courts of justice; and it was regarded as an extraordinary stretch of liberality to allow the formation of a Protestant burial-ground at Quito in 1867. Monkish orders that lost their influence in Europe centuries ago still flourish in Quito—Trinitarians, Dominicans, Augustinians, Brown Franciscans, Black Franciscans, Lazarists, &c. According to Villavicencio, the number of the regular clergy at the time he wrote was 344, and of nunis 391. Quito is the seat of an archbishop, and there are bishoprics for Cuenca, Loja, Ibarra, Rie schamba, Guayaquil, and Manabi.

Education has hitherto been left in the hands of the clergy, and Education primary education is consequently in a very defective condition. There has long been a university at Quito with about a dozen professors and nearly 300 students; and in 1876 an academy was instituted in the city in accordance with the decree of the Spanish academy of Madrid. There are colleges in the larger towns, and public schools have been established all over the country. The normal school at Guayaquil is open to Indian children.

The administrative purposes the country is divided into eleven Provinces provinces—Anay, with 149,103 of a population in 1871; Chumbe rano, 110,860; Funchino, 102,921; Guayas, 87,427; Ibarra, 77,879; Leon, 78,194; Tunguragua, 72,149; Los Rios, 61,923; Loja, 60,784; Manabi, 56,098, Esmeraldas, 8000. Besides the capital, whose inhabitants are variously estimated at 30,000, the largest cities are—Guayaquil, from 16,000 to 25,000, Tungurahua, from 16,000 to 25,000, Cuenca, about 15,000; Riobambas and Ibarra, both perhaps about 16,000; Ambato, about 10,000, Olavalo, about 8000; Guaranda, 9000; and Cotacachi, 4000.

Antiquities. — Throughout Ecuador there are still considerable Anti- remains of the architectural and artistic skill of the anti-European quites period. At Caxar, to the northeast of Guayaquil, is a piece, a circular rampart of finely hewn stone, including an open area with a roofless but well-preserved building in the centre; not far off is the Juncu-chungana, a very much smaller enclosure, probably the remains of a pavilion; and in the same neighbourhood the image of the sun and a small cabinet are carved on the face of a stellated Inta-huasi. Near the upper river Torces, to the south of the Esmeraldas there are remains at Paltamata to a temple and a conical tower, the buttresses of a bridge composed of stone and mortar, portions of a great canal, and numerous houses, which mummies and plates of silver have been obtained. At Han tumas similar sepulchral mounds, called tolas, may be seen, as traces of military structures. At the height of 12,500 feet, the Cotopaxi, at a height of 6568 feet, the ruins of an Inca palace, Fushania, are utilized by the kasenda; and a conical hill at its foot is supposed to be of artificial construction. Another fortress and palace are preserved at Pomezlillas, and in the
neighbouring pueblo of Achupallas an ancient temple of the sun now serves as parish church.

History.

The territory of the present republic of Ecuador, when first it became dimly visible in the gray dawn of American history, appears to be inhabited by upwards of fifty independent tribes, among which the Quitos were the most important. About 200 A.D. a foreign tribe is said to have forced their way inland up the valley of the Esmeraldas, and the kingdom which was founded at Quito lasted for about 1200 years, and gradually extended, both by war and alliance, over many of the neighbouring dominions. In 1469, during the reign of the fourteenth Chimu, or Lord of the Valley, the conquest of Quito was undertaken by Tupa Yupanqui, the Inca of Peru; and his ambitious schemes were not long after his death, completely carried out by his son Huascar-Casca, who inflicted a decisive defeat on the Quitomans in the battle of Hatun-taqui, and secured his position by marrying Fucha, the daughter of the late sipher. By his will the conqueror left the kingdom of Atahualpa, his son by this alliance; while the Peruvian throne was assigned to Huascar, an elder son by his Peruvian consort. War soon began between the two kingdoms, owing to Huascar's pretensions to supremacy over his brother, but it ended in the defeat and imprisonment of the usurper, and the establishment of Atahualpa as master both of Quito and Cuzco. The fortunate monarch, however, had not long to enjoy his success; for Huascar and his Spanish wife were already at the door, and by 1533 the fate of the country was sealed. As soon as the confusion and involve of the first occupation were suppressed, the recent conquest of the Quito province became a reality. The independence began to manifest itself throughout the Spanish colonies of South America. Quito did not remain altogether independent. The Quichuan doctor Eugenio Espejo, and his fellow-exterminates Don Juan Pio Montefaur, entered into hearty co-operation with Narbho and Zeno, the leaders of the revolutionary movement at Quito. When, towards the close of the century, the desire for independence began to manifest itself throughout the Spanish colonies of South America, Quito did not remain altogether independent. The Quichuan doctor Eugenio Espejo, and his fellow-exterminates Don Juan Pio Montefaur, entered into hearty co-operation with Narbho and Zeno, the leaders of the revolutionary movement at Quito. When, towards the close of the century, the desire for independence began to manifest itself throughout the Spanish colonies of South America, Quito did not remain altogether independent. The Quichuan doctor Eugenio Espejo, and his fellow-exterminates Don Juan Pio Montefaur, entered into hearty co-operation with Narbho and Zeno, the leaders of the revolutionary movement at Quito. The typhon, however, came to a sudden close in 1576, when the independence of Quito was proclaimed by three of his private enemies. The consequent election resulted in the appointment of Dr Borrego, who, on his address to the Congress, December 14th, 1875, left the country under the constitution of the responsible office to which he had never aspired, full political liberty and the freedom of the press! An insurrection headed by Venzettini, the military president, had already broken out, and on the 14th December the Government forces under Aparicio were completely routed at Galte.

EDDA---EDD

he sent under Flores to recast the enclosures of Mompox, the present of New Granada, was completely routed. His first regiment in 1644 was refused, but the desultory acts by which he sought to establish a dictatorship only embittered his opponents. In 1646 he retired from office. While he had endeavoured to develop the material resources of the country and to introduce retrograde measures in regard to religion and education. The principal event in the short presidency of his successor, General Juan larrain (1657), was the war with Chili and Peru against Spain, and the banishment of all Spanish subjects. Several important changes were made by congress in the period between his successor's death and the election of Exequias. Jan 1668 the power of the president to impose personal taxes was abolished and the public office was annually renewed. Next year a revolution at Quito, under Moreno, brought Exequias's presidency to a close, and though the national convention appointed Carvajal to the vacant office, Moreno succeeded in securing his own election in 1670 for a term of six years. His policy had undergone no alteration since 1656 the same persistent endeavour was made to establish a religious despotism, in which the supremacy of the president should be subordinate only to the highest supremacy of the clergy. The tyranny, however, came to a sudden close in 1676, when the president was murdered in Quito, by three of his private enemies. The consequent election resulted in the appointment of Dr Borrego, who, on his address to the Congress, December 14th, 1875, left the country under the constitution of the responsible office to which he had never aspired, full political liberty and the freedom of the press! An insurrection headed by Venzettini, the military president, had already broken out, and on the 14th December the Government forces under Aparicio were completely routed at Galte.

EDAM, a town of the Netherlands, in the province of North Holland and arrondissement of Hoorn, about 11 miles north-east of Amsterdam, and lying a mile from the junction of the two branch canals. It has a fine town-house, an exchange, and a fish-market, and one of its two Reformed churches is adorned with stained glass, and ranks among the most beautiful buildings of the kind in the province. Shipbuilding, rope-spinning, and sail-making are carried on, and the place gives its name to a well-known description of "sweet-milk" cheese—Zoemelkaas. It was at Edam that nearly the whole of Admiral De Ruyter's fleet was constructed. Population of the commune in 1869, 5152, and of the town 3556.

EDDA, the original signification of which is "great-grandmother" is the title given to two very remarkable collections of old Icelandic literature. Of these only one bears that title from antiquity; the other is named by a comparatively modern moniker who only works by that name to the ancients was the miscellaneous group of writings attributed to Snorri Sturluson (1178-1241), a scholar of Jon Lofthson, and the greatest name in old Scandinavian literature. It is more correctly known as the Uppsala Codex, transcribed about forty years after his death. The collection of Snorri is now known as the Prose VIII. - 2.
or *Younger Edda*, the title of the *Elder Edda* being given to a book of ancient mythological poems, discovered by the Icelandic bishop of Skalholt, Brynjulf Sveinsson, in 1643, and erroneously named by him the *Edda of Snorri*. 1. The *Prose Edda*, properly known as *Edda Snorra Sturlusonar*, was arranged and modified by Snorri, but actually composed, as has been conjectured, between the years 1140 and 1160. It is divided into five parts, the Prose or *Forfald*, *Gylfaginning*, *Bragararvætur*, *Skáldskaparmál*, and *Háttatal*. The prose bear a very modern character, and simply gives a history of the world from Adam and Eve, in accordance with the Christian tradition. *Gylfaginning*, or the Delusion of Gylfi, on the other hand, is the most precious compendium which we possess of the mythological system of the ancient inhabitants of Scandinavia. Commencing with the adventures of a mythical king Gylfi and the giantess Gefjon, and the miraculous formation of the island of Zealand, it tells us that the Åsir, led by Odin, invaded Svithjod or Sweden, the land of Gylfi, and settled there. It is from the *Ynglingsaga* and from the *Gylfaginning* that we gain all the information we possess about the conquering deities or heroes who set their stamp upon the religion of the North. Advancing from the Black Sea northwards through Russia, and westward through Esthonia, the Åsir seem to have overrun the south lands of Scandinavia, not as a horde but as an immigrant aristocracy. The Eddaïc version, however, of the history of the gods is not so circumstantial as that in the *Ynglingsaga*. It is, on the other hand, distinguished by an exquisite simplicity and archaic force of style, which give an entirely classical character to its mythical legends of Odin and of Loki. *Gylfaginning* is written partly in prose, partly in verse, with brief poetical insertions. *Bragararvætur*, or sayings of Bragi, are further legends of the deities, attributed to Bragi, the god of poetry, or to a poet of the same name. The *Skáldskaparmál*, or Art of Poetry, commonly called *Skáld*, contains the instructions given by Bragi to Eggun, and consists of the rules and theories of ancient verse, exemplified in copious extracts from Eyríndr Skálapsalir and other eminent Icelandic poets. The word *Skáldskapr* refers to the form rather than the substance of verse, and this treatise is almost solely technical in character. It is by far the most important of the sections of the *Edda of Snorri*, and comprises not only extracts but some long poems, notably the *Thorðermál* of Eilífr Guðnason and the *Hauktvang* of Thjóðólfr. The fifth section of the *Edda*, the Háttatal, or Number of Metres, is a running technical commentary on the text of Snorri's three poems written in honour of Hískon, king of Norway. Affixed to some MS. of the Younger *Edda* are a list of poets, and a number of philological treatises and grammatical studies. These belong, however, to a later period than the life of Snorri Sturluson.

The three oldest MSS. of the prose *Edda* all belong to the beginning of the 14th century. The Wurm MS. was sent to Ole Wurm in 1628; the Codex Regius was discovered by the indefatigable bishop Brynjulf Sveinsson in 1640. The most important of the two is the *Upsal Codex*, an octavo volume written probably about the year 1300. There have been several good editions of the *Edda Snorra Sturlusonar*, of which perhaps the best is that published by the Arno Magnus Society in Copenhagen in 1848, in two vols., edited by a group of scholars under the direction of Jón Sigurðsson.

2. The Elder *Edda*, Poetic *Edda*, or *Svemundar Edda* hina frøða was entirely unknown until about 1643, when it came into the Skálaholt, Brynjulf Sveinsson, who, puzzled to classify it, gave it the title of *Edda Svemundar multeci*. Svemund Sigfusson, who was thus credited with the collection of these poems, was a scion of the royal house of Norway, and lived from about 1065 to 1132 in Iceland. The poems themselves date in all probability from the 8th or 9th centuries, and are many of them only fragments of longer heroic chants now otherwise entirely lost. They treat of the most glorious legends of an early Scandinavian civilization, and are composed in the simplest and most archaic forms of Icelandic verse. The author of no one of them is mentioned. It is evident that they were collected from oral tradition; and the fact that the same story is occasionally reported under varied form, and that some of the poems themselves bear internal evidence of being more ancient than others, proves that the present collection is only a gathering made early in the Middle Ages, long after the composition of the pieces, and in no critical spirit. Sophus Bugge, indeed, one of the greatest living authorities, absolutely rejects the name of Æsmund, and is of opinion that the poetic *Edda*, as we at present hold it, dates from about 1240. There is no doubt that it was collected in Iceland, and by an Iceland, the most remarkable and the most ancient of the poems in this priceless collection is that with which it commences, the *Voluspa*, or Prophecy of the Volva or Sibyl. In this chant we listen to an inspired prophetess, "seated on her high seat, and addressing Odin, while the gods listen to her words." She sings of the world before the gods were made, of the coming and the meeting of the Åsir, of the origin of the giants, dwarfs, and men, of the happy beginning of all things, and the end which shall be in the chaos of Ragnarok. The latter part of the poem is understood to be a kind of necromancy,—according to Vígufsson, "the raising of a dead volva," but the mystical language of the whole, its abrupt transitions and terse condensations, and above all the extinct and mysterious cosmology, its unaccountability with which it presupposes nothing less than an exact interpretation of the *Voluspa* extremely difficult. The charm and solemn beauty of the style, however, are irresistible, and we are constrained to listen and revere as if we were the auditors of some fugal music devised in honour of a primal and long-buried race. The melodies of this earliest Icelandic verse, elaborate in their extreme and severe simplicity, are wholly rhythmical and alliterative, and return upon themselves like a solemn incantation. *Hvammr*, the Sayings of the High One, or Odin, follows next; this contains proverbs and wise saws, and a series of stories, some of them well known, told by Odin himself. *The Vigtardsmímal*, or sayings of Víulsáfni, is written in the same mystical vein as *Voluspa*; in it the giant who gives his name to the poem is visited by Odin in disguise, and is questioned by him about the cosmogony and chronology of the Norse religion. *Grimnmímal*, or the Sayings of Grimnir, which is partly prose, is a tale of Odin's imprisonment and torture by king Gertrud. *For Skirmir*, or the Journey of Skirmir, *Hárvarðalíðr*, or the Lay of Harvarð, *Hymskála*, or the Song of Hymir, and *Ögislókar*, or the Brewing of Ógir, are poems, frequently composed as dialogue, containing legends of the gods, some of which are so ludicrous that it has been suggested that they were intentionally burlesque. *Thrymskála*, or the Song of Thrym, possesses far more poetic interest; it recounts in language of singular force and directness how Thór lost his hammer, stolen by Thrym the giant, how the latter refused to give it up unless the goddess Freyja was given him in marriage, and how Thor, dressed in women's raiment, personated Freyja, and, slaying Thrym, recovered his hammer. *Álvismímal*, or the Sayings of Alvis, is actually a philological exercise under the semblance of a dialogue between Thér and Alvis the dwarf. In *Vestamímal*, or the Song of Vé, Odin questions a volva with regard to the meaning of the sinister dreams of Fáðar. *Egilsmímal*, or more properly *Bíthusla*, records how the god Heimdal, disguised as a man called Rug, wandered by the seas-aborde, where he met the original dwarf pair, Ál and Edda, to
whom he gave the power of child-bearing, and thence sprung the whole race of thralls; then he went on and met with Ash and Amma, and made them the parents of the race of churl; then he proceeded until he came to Fafnir and Modir, to whom he gave the first of free men, whom he himself brought up, teaching him to shoot and shun, and to use the sword and runes. It is much to be lamented that of this most characteristic and picturesque poem we possess only a fragment. In Hyndluljóð, the Lay of Hyndla, the goddess Freyja rides to question the völva Hyndla with regard to the ancestry of her young paramour Ótar; a very fine quarrel ensues between the prophetess and her visitor. With this poem, the first or wholly mythological portion of the collection closes. What follows is heroic and pseudo-historic. The Volsungarvölk, or Song of Volsundr, is engaged with the sufferings and adventures of Volsundr, the smith-king, during his stay with Nursed, king of Sweden. Volsundr, identical with the Anglo-Saxon Weland and the German Welant, is sometimes confounded with Odin, the master-smith. This poem contains the beautiful figure of Svanhvít, the swan-maiden, who stays seven winters with Volsundr, and then, yearning for her fatherland, flies away home through the dark forest. Helgaðisvölk Hvarvótt Sonar, the Song of Helgi, the Son of Hvarvótt, which is largely in prose, celebrates the wounding of Helgi by Svan, who, like Atlantus, ends by loving the man with whom she has fought in battle. Two Songs of Helgi the Hunding’s Bane, Helgaðisvölk Hundingbana, open the long and very important series of lays relating to the two heroic families of the Volsungs and the Niblings. Including the poems just mentioned, there are about twenty distinct pieces in the poetic Edda which deal more or less directly with this chain of stories. It is hardly necessary to give the titles of these poems here in detail, especially as they are, in their present form, manifestly only fragments of a great poetical saga, possibly the earliest coherent form of the story so universal among the Teutonic peoples. We happily possess a somewhat later prose version of this lost poem in the Volsungasaga, where the story is completely worked out. In many places the prose of the Volsungasaga follows the verse of the Eddaic fragments with the greatest precision, often making use of the very same expressions. At the same time there are poems in the Edda which the author of the saga does not seem to have seen. But if we compare the central portions of the myth, namely Sigurd’s conversation with Fafnir, the death of Beowulf, the speech of the birds and the meeting with the Valkyries, we are struck with the extreme fidelity of the prose romancer to his poetical predecessors in the Sigurðarvölk Fafnirvölk; in passing on to the death of Sigurd, we perceive that the version in the Volsungasaga must be based upon a poem now entirely lost. Of the further extension of the myth and its corruption into the romantic epic of Der Niebelung-Nibelungenlied, this is not the place for discussion. Suffice it to say that in no modernized or Germanized form does the legend attain such an exquiste colouring of heroic poetry as in these earliest fragments of Icelandic song. A very curious poem, in some MSS., attributed directly to Saxmund, is the Lay of the Sun, Sólarljóð, which forms a kind of appendix to the poetic Edda. In this the spirit of a dead father addresses his living son, and exhorts him, with maxims that resemble those of Hávamál, to righteousness of life. The tone of the poem is strangely confused between Christianity and Paganism, and it has been assumed to be the composition of a writer in the act of transition between the old creed and the new. It may, however, not impossible, be altogether spurious as a poem of great antiquity, and may merely be the production of some Icelandic monk, anxious to imitate the Eddaic form and spirit. Finally Forsympall, or the Preamble, formerly known as the Song of Odin’s Raven, is an extremely obscure fragment, of which little is understood, although infinite scholarship has been expended on it. With this the poetic Edda closes.

The principal MS of this Edda is the Codex Regius in the Royal Library at Copenhagen. It consists of a manuscript, within 8vo., of 45 leaves. This is that found by Bishop Brysur. Another valuable fragment exists in the Arné-Magnússon collection in the University of Copenhagen, consisting of six leaves. These are the only MSS older than the 17th century which contain a collection of the ancient mythic-heroic lays, but fragments occur in various other works, and especially in the Edda of Snorr. The poetic Edda was translated into English verse by Amos Cottle in 1797, the poet Gray produced a version of the Fóstatarvölk, but the first good translation of the whole was that published by Benjamin Thorpe in 1866. An excellent edition of the Icelandic text has been prepared by Professor Hjalmar Skjærvø, commencing in 1871, and Professor Edelinck ultimately took the first rank among his examiners. His excellence was generally acknowledged; and having become known to Louis XIV. he was appointed, on the recommendation of Le Brun, teacher at the academy established at the Gobelins for the training of workers in tapestry. He was also entrusted with the execution of several important works. In 1767 he was admitted member of the Paris Academy of Painting and Sculpture. The work of this great engraver constitutes an epoch in the art. His prints number more than four hundred, and it is asserted that amongst them there is no work of poor or middling quality, although many of his subjects were poor and unworthy of the high art which he lavished upon them. Edelinck stands above and apart from his predecessors and contemporaries especially in this that he excelled, not in some one respect, but in all respects,—that while one engraver attained excellence in rendering light and shade, and others in giving colour to their prints and the texture of surfaces, he, as supreme master of the burin, possessed and displayed all these separate qualities, and that in so complete a harmony that the eye is not attracted by any one of them in particular, but rests in the satisfying whole. Edelinck was the first to break through the custom of making prints square, and to execute them in the lozenge shape. Among his most famous works are a Holy Family, after Raphael; a Penitent Magdalene, after Charles Le Brun; Alexander at the Tent of Darius, after Le Brun, a Combat of Four Knights, after Leonardo da Vinci; Christ surrounded with Angels; St Louis praying, and St Charles Borromeo before a Crucifix,—the last three after Le Brun. Edelinck was especially good as an engraver of portraits, and executed prints of many of the most eminent persons of his time. Among these are those of Le Brun, Rigaud, Philippe de Champagne (which the engraver thought his best), Santeuil, La Fontaine, Colbert, John Dryden, Descartes, &c. He died at Paris in 1707. His younger brother John, and his son Nicholas, were also engravers, but did not attain to his excellence.

EDEN, Hebrew (775, denoting pleasure or delight), was the first residence of Adam and Eve according to the Old Testament Scriptures. The passage in which its geographical position seems to be indicated (Gen. 2:8) has been from the earliest times the subject of a discussion as ingenious and elaborate as it has been fruitless. Its
general position is given as "eastward," i.e., to the east of the place where the narrative was written. Of the four rivers mentioned the Euphrates is undoubtedly the same which is still known by that name, and the Hiddokel has been almost universally identified with the Tigress. The object of commentators who have sought to put a literal construction on the passage has, therefore, been to identify the Euphrates with the Tigress, and to find two rivers which together with the Euphrates and the Tigress fail to the condition stated in Gen. ii. 10, "And a river went out of Eden to water the garden; and from thence it was parted and became into four heads." As there is no river which forms a complete source for the Euphrates, the Tigress, and two others, recourse has been had to a strained construction of one kind or other. Josephus, for example, supposes the river which is the common source to have been the ocean stream which surrounds the earth, and identifies the Pison with the Ganges and the Gihon with the Nile; and in this he is followed by many of the fathers. Calmet, Rosenmüller, and others, again, suppose the river which is the common source to have been a region of springs, and, by making the Pison and the Gihon mountain streams, place the site of Eden in the highlands of Armenia. Calvin, Huet, and Bochart place Eden in lower Babylonia, on the supposition that the Pison and the Gihon are the two channels by which the united rivers Euphrates and Tigress enter the Persian Gulf. Luther and others, such as Clericus and more recently Baumgarten, have hazarded the supposition that the flood altered the course of the streams, and thus rendered it impossible to identify the locality of Eden from the description given in Genesis. These may suffice as specimens of the almost innumerable solutions that have been offered of what is now generally admitted to be an insoluble problem. On the theory that the narrative in Genesis is veritable history to be literally interpreted, it is impossible to determine the geographical position of Eden with any approach to certainty. This impossibility fully accounts for the immense variety of the conjectures that have been put forward. It deserves mention as a curiosity of criticism that the site of Eden has been assigned by different writers to each of the four quarters of the globe, and that the particular localities assigned have ranged from Scandinavia to the South Sea Islands. The allegorical interpretations, which have been offered in great variety from the time of Philo downwards, are, of course, not hampered with any geographical difficulties. Philo supposes Eden to be a symbol of the soul that delights in virtue, the river which is the source to be good, and the four rivers to be the specific virtues of prudence, temperance, courage, and justice. Origen finds in the subject an excellent opportunity for applying his favourite allegorical method, and supposes Eden to be heaven, and the rivers wisdom. Similar interpretations, with individual variations, are given by several of the fathers who are prone to allegorize. In modern times Coleridge is perhaps the most celebrated of those who have interpreted the story of Eden as an allegory. It is to be observed, however, that this mode of explaining the narrative has found even less favour with recent interpreters than that which accepts it as literal history, meeting the obvious difficulties as best it can. The undoubted tendency of later criticism has been to discard alike the theory of literal history and the theory of allegory in favour of another, according to which the story of Eden is a mythical tradition of a kind similar to that which is to be found in the early sacred literatures of most nations. According to this view, the true explanation is to be sought for in that fruitful comparison of these various traditions as preserved in sacred scriptures, early histories, inscriptions, and otherwise. See Adam, vol. i. p. 135-6, and Pentateuch.

EDEN, The Honorable Emily (1795-1851), novelist and miscellaneous writer, was the seventh daughter of the first Lord Auckland, and was born in 1795. Happily gifted by nature, her literary faculties and tastes were fostered by a liberal education. In 1835 she accompanied her brother, Lord Auckland, to India, on his appointment as governor-general, and remained with him during his term of office, which covered the period of the Afghan war. Returning to England in 1841, she made herself favourably known as a writer by the publication, three years later, of her Portraits of the Princes and People of India. She was also author of two novels entitled The Semi-detached House and The Semi-detached Couple, first appeared anonymously under the editorship of Lady Theresa Lewis. In these works she gives clever and amusing delineations of Anglo-Indian life and manners as she saw them. In 1886 was published a series of her letters to her sister written from India, and entitled Up the Country. Her private journal, at present unpublished, is said to be still more attractive and full of sparkling anecdote and graphic sketches. Another volume entitled Letters from India, edited by her niece, the Hon. Eleanor Eden, was published in 1872. For many years Miss Eden lived at Berne, and in 1876 was one of the most frequent centres of London intellectual and fashionable life. She afterwards removed to Richmond, and there died, August 5, 1886. Her eldest sister Eleanor attracted the warm affection of William Pitt, who, however, did not feel justified in making her an offer of marriage. This was, it is supposed, the only love passage in Pitt's history. She afterwards married Lord Hobart, and died in 1881.

EDENTATA, an order of placental mammals characterized by the total absence of median incisor teeth. Such teeth as are found in edentate species are composed entirely of dentine and cement, without enamel; they likewise grow for an indefinite period, and are consequently without root; and so far as yet discovered there is no displacement of the first teeth by any second set except in a few of the armadillos. This order contains the sloths, armadillos, and ant-eaters.

EDESSA, the ancient capital of Macedonia, previously known as Aigeae, was situated 46 miles W. of Thessalonica on the banks of a beautiful stream in the very centre of the kingdom, and at the head of a defile commanding the approaches from the sea-coast to the interior of the country. It was the original residence of the Macedonian kings; and even after the seat of government was removed to the more accessible Pelia, it continued to be the burial-place of the royal family. At the celebration of his daughter's marriage in the town, Philip II. was murdered by Pausanias in 336 B.C. His greater son Alexander was buried at Memphis through the contrivance of Ptolemy; but the bodies of his grand-daughter Eurydice and her husband Arrhidæus were removed by Cassander to the ancestral sepulchre. On the occupation of the town by Erythra the royal tombs were plundered by the Gallic mercenaries. The modern city of Vodena is built on the site of Edessa, and preserves a few unimportant remains of ancient buildings. The names Aigeae and Edessa were both probably given in allusion to the full-flowing streams that form one of the principal features of the situation; and Vodena is certainly derived from the Slavonic voda, water. Full details in regard to the position of the city may be found in Tozer, The Highlands of Turkey, vol. i.

EDESSA, or, as it is now called, Urfa or Orfa, a city of Northern Mesopotamia, on the Euphrates, 78 miles W. of Diarbekr, 28 miles N. of Birejik, in 37° 21' N. lat. and 39° 6' E. long. It is surrounded with walls and towers, well preserved on the northern side, has narrow but comfortable and cleanly
EDF, streets, and displays in its bazaar not only the native woolen stuffs, pottery, and silver work, but also a considerable variety of European goods. In the principal square there is a large mosque dedicated to Abraham, who, according to Mahometan legend, was slain in the city; and in its immediate vicinity is a pond shaded by fine pomegranate trees, and cypress trees, and tenanted from time immemorial by sacred fish. The only ancient remains are those of a tower associated by tradition to Nimrod, but in the neighbourhood there exist extensive catacombs with numerous inscriptions of an early date. The prevailing language is Turkish, though more than three-fourths of the inhabitants are Christian. The population was estimated about 1796 by Oliver as from 20,000 to 24,000, by Buckingham at 50,000, and, in 1873, by Chernik at 40,000. 

The town is the capital of a district, an American French, and in connection with the former a school with about 250 pupils. The outskirt is occupied by meadows, vineyards, and mulberry plantations.

Nothing is known of the origin of Edessa. It has been suggested that the early inhabitants were Sabaeans, and that the sacred fish originally belonged to the worship of Astarta. According to the Tarquin of the pseudo-Jonathan, Jerome, and Ephraim Synagoga was identified with the Ezech of General 10, and the local tradition of the Arabs and Jews makes it the same as Ur of the Chaldees; but there is no historical basis for these identifications, though the former has received the sanction of Micahelis, Ruttmann, and Von Bethlen. The first authentic mention of the city connects it with Seleucus, who appears to have granted it autonomy, and was probably the bestowal of the name by which it is best known in history. This, according to Stephans, was taken from the Macedonian Edessa, from the abode of the water in both cities, but a modern etymologist recognizes the Syriac Haditha or New Town. Another designation, Callirhoe, found in the ancient writers, undoubtedly alludes to its fountain, and it is at least possible that this may be the derivation of its modern name—Urinh or among the Syrachs, Er Rehah among the Arabs, and Orich among the Turks and Christians. In the time of Antiochus VII., about 125 B.C., the city became the seat or centre of the Orisvoidion kingdom, founded by Oricho Bar-Chermey, and governed for centuries by a series of elective monarchs. Of these the eighth in succession, Abgar Bar-Abgar, fought against Lucullus, but afterwards sided with the Romans; the fifteenth Abgar Echeneus, as famous for the legendary correspondence with Christ reported by Eusebius, was the city plundered by Trajan's general Lusius Quettus, and the kingdom became tributary in 116 Restored by Hadrian it was finally ablished by Constantine in 317, and a Roman military colony was established with the title of Colonia Maron Edesorum. Meanwhile Christianity had been taken by the city, the first church having been built early at least as 292. By the time of Julian, the wealth of the Christians was sufficient to attract the attention of the Emperor, and in the course of the following centuries the number of monasteries and churches in the city was so increased that the name of Edessa came to be used for the whole province. At that time the city was in the province of Edessa, comprising the Eastern part of the Seleucia of Abgar, and including the towns of Abgar, Marone, and some other cities. The city was of great importance as a centre of the Christian church, and was the seat of a bishop and the see of a metropolitan. The name of Edessa was derived from the Greek Apollo, and was afterwards corrupted into Edessa, and then into Edfu.

EDFU, in Coptish Abto, from the old Egyptian Tebu, a village of Upper Egypt, in the province of Saaid, situated about a third of a mile from the left bank of the Nile, 55 miles below the cataracts of Syene, in 24° 36' 43'' N. lat. It is inhabited by about 2000 Arabs and Copts, engaged for the most part in the manufacture of earthenware, which finds ready sale all through Egypt, and is remarkable for the fineness of the pottery. In the workmen who are employed in the manufacture of the pottery, which is considered the best in the world, and is used for the ornamentation of the tombs. To the Egyptologist the spot is of extreme interest, as furnishing the most perfect specimen of an Egyptian temple, full details in regard to which may be found in the article Abydos, vol. n. p. 389. By the Greeks and Romans the city to which this splendid building belonged was known as Apollonopolis Magna, the god to whom the temple was dedicated being identified with the Greek Apollo. Under the later empire it was the see of a bishop and the head-quarters of the Legato II. Trajan. See Beloni, Narrative, 3d ed., 1832, Wilkinson, Egypt and Nubia, 1843; Lepsius, Unter den hurrgogischen Inschriften am Tempel von Edfu, Berlin, 1855; Mariette, Fouilles en Egypte, 1867.

EDGECOWTH, Maria (1767-1849), the creator of the novel of national manners and moral purpose, was the daughter, by his first wife, of Richard Lovell Edgeworth noticed below. She was born at Hare Hatch, Berkshire, in 1767, and did not see Ireland till she was twelve years old. She was educated by her father, who imbued himself with great enthusiasm to the intellectual advancement of his children. In most of her literary undertakings Miss Edgeworth had the advantage of her father's criticism, who also wrote introductions to her novels. "It is my business," he used to say, "to cut and correct, yours to write on." Many tales and essays were written by Maria for private pleasure before publication was thought of. Practical Education (1795) was a joint work by father and daughter. In 1809 appeared Castle Rackrent, which at once made for her a reputation as a national novelist. This was followed soon after by Eveline, and by the Essay on Irish Bulls, published in partnership with his father, and intended to familiarize the English public with Irish humour and pathos. The work is so thoroughly the joint-product of two minds, that Miss Edgeworth, in writing her father's life, cannot tell distinctly which parts are his, but says that passages in which classical allusions and quotations occur must be her father's, as she was "entirely ignorant of the learned languages" (Memoirs, second edition, p. 117). In 1804 appeared Popular Tales, in 1806 Leonora, in 1809 the first installment of Fashionable Tales, which were finished in 1812; in 1814 Patronage, and in 1817 Harrington, Ormond, and Comic Dramas, which failed on the stage. The death of her father, in that year, recalled her from novel writing to fulfill the sacred duty of completing his Memoirs, which were given to the world in 1820, and of which a second edition was called for in 1821. In 1822 appeared Rosamond, a Sequel to Early Lessons, a work published earlier with contributions from Mr. Edgeworth's pen. In August 1823 Miss Edgeworth visited Sir Walter Scott at Abbotsford, where she remained a fortnight; and Scott repaid this visit at Edgeworthstown exactly two years afterwards. In 1825 Miss Edgeworth further continued her tales for the young by the publication of Harry and Lucy. In 1824 appeared Helen, a Tale, her last and one of her best novels; and she afterwards wrote Orlando, a book for children. Her Letters for Literary Ladies were suggested by a correspondence between Thomas Day and her father as to the propriety of "female authorship," in which the former stoutly maintained the case. Miss Edgeworth died on the 21st of May 1849, after having lived to see her works take rank as English classics. Her influence was deep and lasting. Sir Walter Scott confesses that he was anxious to do for Scotland what Miss Edgeworth had done for Ireland; and it is said that "O'Connell regretted deeply that one so powerful did not serve Ireland as an agitator. Her society was courted by
the most distinguished of her contemporaries; and countless tourists, who visited her, returned home charmed by her lively conversation (1837 edition, page 231). She was the centre of the home in which she was the centre. With Scott she was on terms of the closest intimacy; Byron admired her works, in spite of his sarcastic reference to "Miss Edgeworth's novels stepping from their covers;" and Lord Macaulay was one of her most enthusiastic worshippers. "Among all the incidents," says Mr Travelsly, "connected with the publication of his History, nothing pleased Macaulay so much as the gratification that he contrived to give to Maria Edgeworth, as a small return for the enjoyment which, during more than forty years, he had derived from her charming writings." Macaulay mentions Miss Edgeworth's name in a note, in which he describes her delineation of King Corny, in Ormond, as "that admirable portrait." Miss Edgeworth, in a letter to Dr Holland, speaks of the "self-satisfaction, vanity, pride, surprise, I had in finding my own name in a novel."

Castle Rackrent, the first and one of the most characteristic of her novels, is lit up throughout with sunny Irish humour, Sir Condy complaining that he "was very ill used by the Government about a place that was promised him and never given, after his supporting them against his conscience very honourably." Leonard has a painful plot. It treats of the seduction of an attached husband by a professed friend of his wife. Leonard's forbearance, however, and her deep-seated love for her husband prove, in the end, too much for the hollow professions and vanity of "Olivia. The Tales of Fashionable Life include Earnest, The Don, Manoeuvring, Almeria, Vivian, The Absentee, Madame de Fleury, and Emilie de Coulanges. Earnus is a powerful story, and relates how the earl of Glanthorn was cured of the disease which gives his name to the book. There are several fine character studies, including the Esxt; M'Leod, the cool, but faithful, Scotch agent; witty Lady Geraldine; Christy, the blacksmith; and Ellinor, the Irish foster nurse, who said, on one occasion, that "if it pleased God, she would like to die on a Christmas day, of all days, because the gates of Heaven, they say, will be open all that day, and, who knows but a body might slip in unknown at this?" (1857 edition, p. 231). The Don portrays, with a realism almost too painful, the dreadful privations undergone by the poor who are unable to get in the money justly their due. Manoeuvring depicts the efforts of Mrs Beaumont, a clever, scheming, deceitful woman, to marry her son and daughter contrary to their inclinations. For a while all seems to go well with Mrs Beaumont, until she is herself entangled in her net of false lies, and finally thoroughly outwitted. Her character, and that of Mr Palmer, a wealthy merchant from Jamaica, are worthy of the author's high reputation. Almeria traces the rise of the worldly spirit in the breast of a young girl, and the debasing consequences of a passionate pursuit of fashion for its own sake, unredemed by any ennobling feature. Vivian is an admirably told story, and illustrates the terrible evils which sometimes arise from indiscretion of character. Vivian, the undeceived, brilliant, young noble; Russell, the faithful tutor, Wharton, the unscrupulous politician and voluptuary; self-willed Lord Glatinbury; prim Lady Glistenbury; and vivacious Lady Julia seem to start from the canvas. The Absentee, considered by many as Miss Edgeworth's masterpiece, is written to expose the misery entailed on the tenantry by the Irishantry, who deserted their native country for London, and who are ably managed by unscrupulous agents. The characters are among the most life-like in the annals of fiction. Lady Clonbrony makes herself exquisitely ridiculous in her vain endeavours to act the fine English lady; Lord Colambre, the hero of the novel, travels, under an assumed name, among his father's tenantry, to learn the condition of the half-dead in which they have been oppressed, and champions their cause so skilfully as to win over even Lady Clonbrony; Lady Dashfort and her daughter are wonderfully real representations of heartless women of fashion; the sufferings of the Irish peasantry are drawn with a loving and masterly pencil; and the general sadness of the work is relieved by humorous sketches as Colonel Heathcck, Sir Terence O'Fay, and Larry Brady, whose inimitable letter closes the book. Macaulay considered the scene in which Lord Colambre discovers himself to his father's tenantry the best passage of the kind since the beginning of the 22d book of the Odyssey. This is very high praise, especially when we remember that Macaulay seems to have read almost every novel—so much was he fascinated by narrative composition.

Madame de Fleury is the story of a French lady who set up a school in Paris for neglected girls. The school came to grief at the great Revolution; and its benevolent founder had to fly to England, where she was supported mainly by donations from the girls, who were instigated by Victorie, the heroine of the book. Ultimately her return to France was secured by Basile, Victorie's lover, who had obtained influence with his general through his valuable engineering knowledge. Emilie de Coulanges describes the misfortunes two French refugees had to undergo in living with Mrs Somers, an excessively ill-tempered English lady, who was generous enough with her money, but neglectful of kindness of a more delicate order. Mrs Somers's incessant outbursts of temper and reconciliations with Emilie, to be followed inevitably by fresh quarrels, are somewhat wearisome reading. The Modern Griselida, a story treating of the attempts of a wife to bring her husband to abject submission, manifests fine satiric power, and great liveliness—the dialogue being particularly animated. Patronage, which is in the same vein as the Tales of Fashionable Life, rather disappointed the critics, who concluded that Mr Edgeworth had written considerable parts of it. Thus, however, is expressly denied by Miss Edgeworth (Memoirs, ii. 323). Ormond is an Irish tale, and ranks among the best of Miss Edgeworth's works. It shows how a youth, whose education had been neglected, and whose temper was naturally impetuous, managed to reach true nobility of character. King Corny, Ormond, Sir Ulick O'Shane, Mortarty Carroll, Dora, and Mademoiselle O'Faley are masterfully creations. There is a true Irish ring about the book, although it is composed in the purest English. Helen is a novel of thrilling interest, and displays greater passion and a finer insight into the more subtle moods of the human mind than any of Miss Edgeworth's previous works. The moral is that falsehood and deceit almost invariably bring misery in their train. Although on a more elaborate scale than her other books, Helen surpasses them all in grace, charm, and lightness of touch. Such powerfully conceived characters as Lady Davenant, Helen, Cecilia, Beaucherc, Churchill, and the Claremonds, leave an indelible impression on the memory.

Miss Edgeworth's novels are distinguished by good sense, humour, and an easy flowing style. As the construction of a plot is not her strong point, she is generally more successful in tales than in lengthy novels. The vivacity of her dialogues is extraordinary; and in them her characters reveal themselves in the most natural way possible. Her books are character-studies, rather than intensely interesting narratives. Sobriety of judgment is seen throughout; and passion, romance, and passion, are never shed their lustre on her pages. Three of her sons were to paint national manners, to enforce morality, and to teach fashionable society by saturating their affairs with simplicity. One expressly calls some of her stories "Moral Tales"; but they all fall under this category. The two poles of thought in regard to the moral tendency of Miss Edgeworth's works are well represented by Robert Hall, the eminent Baptist preacher, and Monsieur Taine.
EDGЕWORTH

565

Miss Edgeworth "does not," says Hall, "attack religion or infirmity against it, but makes it appear unnecessary by exhibiting perfect virtue without it. No books ever produced so bad an effect on mankind as the "Philosophiæ Naturalis" (Hall's Works, vol. i., 1846, appendix, note A). Monsieur Taine, again, says that "this regular presence of a moral satisfaction spoils the novel as well as the novel. It must be confessed a volume of Thackeray has the cruel misfortune of recalling the novels of Miss Edgeworth."

(English Literature, Criticisms, Notes, &c., page 37).

To Robert Hall's criticism it is to be objected that a novel is scarcely the place to explain and illustrate the systematic theology of the evangelical school; while we are not content to discuss and the French philosopher, that to burden a novel with a moral, or other special purpose, is artistically a blunder, especially when it is professedly made an instrument for the instruction of the young of Sir Walter Scott, that "his morality is not in purple patches, ostentatiously obtruded, but woven through in the very texture of the story, as the garment of the author's own noble character, which ever responded to his invention, is his" (Memorials, ii. 144). His home was now at Hare Hatch, in Berkshire, where he endeavoured to educate his son according to the method explained in Rousseau's Emile. In later life, however, he saw reason to doubt many of Rousseau's views (Memorials, ii. 574). At the same time he went on keeping terms at the Temple, and formed the greatest friendship of his life with Thomas Day—an able man, of noble character, excessively eccentric, and known to all boys as the author of Samford and Merton, which was written at Edgeworth's suggestion in 1769, on the death of his father, he gave up the idea of being a barrister; but, instead of immediately settling on his Irish estate, he spent a considerable time in England and France, more delightfully happy. Edgeworth returned to Lichfield, to Dr Erasmus Darwin's, one of his greatest friends, and at once declared his passion for Miss Honora Sneyd, which had been the cause of his flight to France two years before. They were married (1773) in the cathedral, and after residing at Edgeworth for three years, settled at Northchurch, in Hertfordshire. When six years of great domestic happiness had elapsed, Mrs Honora Edgeworth died, after recommending her husband to marry her sister Elizabeth—which he did, on Christmas Day 1780. In 1782 Edgeworth returned to Ireland, determined to improve his estate, educate his seven children, and ameliorate the condition of the tenants. Up to this point Edgeworth has told his own story. The rest of his life is written by his daughter, and opens with an account of the improvements he effected, and a lengthy panegyric on Mr Edge- worth as a model landlord (Memorials, ii. 12-36).

In 1785 he was associated with others in founding the Royal Irish Academy; and, during the two succeeding years, mechanics and agriculture occupied most of his time. In October 1787, his friend Day was killed by a fall from his horse, and this trial was soon followed by the loss of a daughter, who had just reached her Fifteenth
year. The first thing that broke the monotony of his grief was the arrival of Dr Darwin's poem, the Botanic Garden, about which the author says, "It was your early approbation that contributed to encourage me to go on with the poem" (Memoirs, ii. 113). In 1792 the health of the

of Edgeworth's sons took him to Clifton, where he remained with his family for about two years, returning in 1794 to Edgeworth's words to Lord Charlemont on the Telegraph; and his apparatus is explained in an "Essay on the Art of Conveying Swift and Secret Intelligence," published in the sixth volume of the Transactions of the Royal Irish Academy.

In the autumn of 1797 Mrs Edgeworth fell a victim to decline. A full account of the matter is given in Edgeworth's letter to Lord Charlemont on the Telegraph; and his apparatus is explained in an "Essay on the Art of Conveying Swift and Secret Intelligence," published in the sixth volume of the Transactions of the Royal Irish Academy.

croptns ripen early; two miles nearer the hills and 200 feet higher the harvest is ten days later; and at an elevation of 600 feet another week at least intervenes.

The total area in cereals was 158,186 acres. The quantity of wheat grown is gradually increasing, in 1866 it was 32,120 bushels, in 1876, 44,560 bushels in contrast to 10,123 in 1856. The average produce in the more fertile districts is 31 bushels per acre, in the poorer districts from 24 to 25 bushels. The roots of all vegetables, especially turnips, are attacked severely by the larvae of the crane-fly (Tipula oleracea), and the ears sometimes suffer from the wheat-maggot.

Of other cereals there were barley 10,153 acres in 1866, and 11,952 in 1876 (the return varying from 42 to 68 bushels), and oats 23,121 in 1866, and 21,314 in 1876. Beans declined from 826 acres in 1866 to 467 in 1876. The area of sown grasses has greatly extended, being 29,907 acres in 1866, and in 1876, 51,869 acres.

The grass-seed is usually put in with the barley crops. Near the city sewage-farm has been carried on to a remarkable extent.

The Craingentanny meadows between the city and the sea, comprising 200 acres, have been under sewage cultivation for upwards of 30 years. The produce, now consisting principally of natural grasses, is sold at from 2½ to 28 per acre, and the whole from £3000 to £4000 per annum. About 30 acres are under similar treatment at Lochend, 70 acres at Dalry, and at the Grange. The total produce of the whole area under irrigation is estimated at £6000. The acreage of turnips in 1866 was 14,517, in 1876, 13,342. About 16 or 18 tons of swedes, or 24 to 24 tons of common turnips, is considered a good crop for first-rate land. Potatoes hold much the same position as in former years, though the demand for them is not so great. A considerable quantity is despatched to England for seed purposes, while the seed required in the country is obtained from Lanark, or the neighbouring counties. The number of cattle was in 1862, 13,013, in 1876, 15,561. In the neighbourhood of Edinburgh especially flax-bearing forms a very important industry; the number of flax-cows in the county is probably 11,000 or 12,000, of which 1800 or 2000 are kept in the town or suburbs, while supply abut half of the man necessary for the local consumption. Sheep are returned as 113,478 in 1866, and 168,565 in 1876. Very few farms are bled in the county, but several of the studs are of excellent character. The Clydesdale breed predominates. Pigs form a very small item in the list of stock, and the poultry yard is of but of secondary importance only in the neighbourhood of the city. The crops rotations vary considerably in different districts. Oats, potatoes, wheat, turnips, barley, hay or pasture is a common order, while a five-course shift of oats, potatoes and turnips, barley or hay, pasture, or a six-course shift (oats, beans, wheat, turnips, barley, grass), is used elsewhere. The average size of farms is 131 acres. According to the returns, out of a total of 1012 holdings 477 did not exceed 50 acres, 116 lay between 50 and 100, 20 were over 100 and under 200, 75 were between 200 to 500, and only 20 were more than 500 acres. Of nineteen years are common, the change of proprietor is as frequent as that of the tenants, and in some cases the same tenant has continued to hold a farm under six or eight successive landlords.

The average value of the arable land is calculated at from 4 to 5 shillings the acre, that of the upland pastures at from 10 to 15 shillings. The whole of the county has been drained more or less thoroughly, and some portions twice over. Tiled and small stone houses began to be built about 1830, and in the last two or three years the demand for them has increased to about 36 feet; and since 1846 deeper drains, with pipes and collars, have been put into the intermediate furrows.

Great improvements have been effected not only in the farm-houses and stables since 1835, but also in the cottages for the labourers. The hay and straw mowings they have been largely increased, and the steam plough has hitherto been very partially adopted.

The nursery grounds of Mid-Lothian are more extensive than those of any other county of Scotland; and in the variety and quantity of their productions they are equal to any in Britain. To orchards proper there are devoted about 12,000 acres, and to fruit-drinking-machines and grading mills not uncommon. The reaping-machines have been generally adopted within the last 20 years, except for very difficult ground, or where the crop has been laid by wind or rain. The assistance of the steam plough has hitherto been very partially obtained.

of Morton (Dalmahoy), 6944; G. K. E. Fairholm, 6200; Charles Cowan (Loganhouse), 5677; John Northwick (Crockston), 5832. The duke of Buccleuch's property, though comprising only 85 acres, is the highest on the valuation roll (£28,296, with the exception of that of the railway companies.

Minerals.—Though not a mining district par excellence, Mid-Lothian possesses a considerable amount of mineral wealth. There are 10 collieries, which in 1875 employed 2179 persons and raised 715,503 tons of coal. With the exception of 90,000 tons raised in the parish of West-Calder, this was all obtained in the valley of the Esk. In its general character the coal does not differ from ordinary Scotch coal; but a large quantity of the best cannel coal, used for making gas, is procured at Niddrie Colliery, and from the marquess of Lothian's mines at Newbattle and Dalkeith. The depth of the pits varies from 50 to 180 fathoms. On the east side of the Esk the strata lie at an angle of from 10° to 14°; those on the west side, at Niddrie and Gilmerton, at from 60° to 90°. Of blackband ironstone about 61,262 tons were raised in 1876, principally in the parishes of Lasswade and Penicuik; and 25,172 tons of fire-clay were obtained in the county. In the vicinity of West-Calder there is a large amount of shale, containing from 50 to 60 per cent. of sandstone, which have been exported to England for docks and for the supply of road-metal are scattered about three miles to the east; Musselburgh, an agricultural and fishing town near the mouth of the Esk; Dalkeith, a market-town and borough of barony; Corstorphine, with a convalescent hospital and an ancient collegiate church containing several tombs of the Forrester family, who became possessors of the fees in 1354, erected in 1404, into a principality for the eldest son of the Scottish king; Crummur, formerly a place of much more importance than now; Mid-Calder, with a church of considerable antiquity, adorned with the armorial bearings of the Sandilands family, West-Calder, Balerno, Currie, Juniper Green, and Colinton, all manufacturing villages; Liberton, deriving its name from the lepers who once were its principal inhabitants; Gilmerton, mainly inhabited by coal-miners and carters; Lasswade, Loanhead, Roslin, and Penicuik.

The population of the entire county in 1871 was 328,579, of whom 153,922 were males and 174,657 females. Excluding the boroughs of Edinburgh, Leith, Portobello, and Musselburgh, the population of the county proper numbered in 1851, 57,843 persons, and in 1871, 74,126, indicating an increase of 28 per cent. within that period. The increase occurs principally in the parishes of West-Calder, Lasswade, Colinton, Dalkeith, and Kirknewton.

Antiquities.—It is believed that Crummond was once a Roman seaport; and various objects of Roman art have been discovered in the vicinity and upwards along the bank of the Almond. On several heights are remnants of early military works—the most important being that on Dalmahoy Hill, Braidwood Castle, a modernized fort on which Hengist and Horsa. Roselin, and Penicuik, and Musselburgh, an agricultural and manufacturing town near the mouth of the Esk; Dalkeith, a market-town and borough of barony; Corstorphine, with a convalescent hospital and an ancient collegiate church containing several tombs of the Forrester family, who became possessors of the fees in 1354, erected in 1404, into a principality for the eldest son of the Scottish king; Crummur, formerly a place of much more importance than now; Mid-Calder, with a church of considerable antiquity, adorned with the armorial bearings of the Sandilands family, West-Calder, Balerno, Currie, Juniper Green, and Colinton, all manufacturing villages; Liberton, deriving its name from the lepers who once were its principal inhabitants; Gilmerton, mainly inhabited by coal-miners and carters; Lasswade, Loanhead, Roslin, and Penicuik.

The following are among the most interesting of the Roman remains in Mid-Lothian not within the limits of the larger towns and villages. Roslin chapel, founded by the St Clairs in 1446, is one of the most highly decorated specimens of Gothic architecture in Scotland, and presents a remarkable combination of peculiarities. Roslin Castle, the seat of the St Clairs, is a fine ruin, occupying a peninsula on the banks of the Esk, and must have been a very strong position before the days of cannon. Hawsmore, a little further down the stream, is interesting as the residence in the 17th century of Drummond the poet, as well as for the strange caves in the rock on which it is built. Dalhousie Castle, the seat of the earl of Dalhousie, is a modern and well-built residence in the classical style on the banks of the South Esk; and Newbattle Abbey, the seat of the marquess of Lothian, occupies the site of the ancient Cistercian monastery a few miles down the stream. Crammogill Castle is a fine ruin on a knoll three miles from Roslin.
EDINBURGH

miles to the south of Edinburgh, which formerly was the residence of the Preston family, and afforded shelter on various occasions to Queen Mary. Bothwell Castle, also a temporary residence of the unfortunate queen, is a double tower on Middleton Burn, still bearing the marks of the old cannon balls. Crichton Castle, a mile and a quarter to the east, was the residence of the well-known family which produced the celebrated Sir William Crichton, and its ruins show "the builders' various hand." Dalmauny Castle, near Ratho, is the seat of the earl of Morton, and preserves, besides other valuable antiquities, the only extant copy of the Bible of the Scottish Parliament, and the original warrant for committing Queen Mary to Lochleven. Melville Castle, near Lauswade, the seat of the earl of Melville; Colinton House, the seat of Lord Dunfermline; Calder House, the seat of Lord Torphichen, Riccarton, belonging to Sir William Gibson Craig, Bart. and Lauriston Castle, once occupied by John Law of Mississippi notoriety, may also be mentioned. Temple, on the South Esk, was at one time the chief seat of the Knights Templars in Scotland.

The history of the county is of little importance apart from that of the city of Edinburgh. Traces of early Celtic occupation still remain in such names as Inveresk, Almond, Leith, Dalry, Dalmauny, Dalkeith, &c.; though by far the greater proportion of the villages, hamlets, and castles have received their present designation from Saxon possessors. The termination -ton is very frequent. Within the county lie the battlefields of Boroughmuir, where the English were defeated by the earl of Murray in 1354; Pinkie, near Inveresk, where the duke of Somerset inflicted tremendous loss on the Scotch; and Rullion Green, on the eastern slopes of the Pentlands, where the Covenanters were routed by the royal troops under General Dalziel.

EDINBURGH, the ancient capital of Scotland, as situated in the county of Mid-Lothian or Edinburgh, to the south of the Firth of Forth. The Royal Observatory, which is built on the summit of the Calton Hill, in the north-eastern quarter of the city, is in 55° 57' 23" of N. lat., and 12° 43' 05" of time W. long. of the meridian of Greenwich. The site of Edinburgh is altogether remarkable as that of a large city, and is the chief source of its peculiar characteristics. It occupies a group of hills separated by deep ravines, and is the central feature of a landscape of rare beauty. The county of Mid-Lothian forms towards the south-east a wild hilly district, diversified with fertile cultivated tracts, but, over an extensive area, broken into a rough pastoral country, rising at various points to upwards of 2000 feet above the level of the sea. On the north it is bounded by the Firth of Forth, from the shores of which the ground slopes gradually towards the south till it merges in the range of the Pentland Hills, with its contour diversified by various undulations and abrupt heights. On this irregular ground, amid the outlying spurs of the Pentlands, a bold cliff of trap-rock, which rises through the sandstone strata of the district, appears to have early attracted attention from its capacity for defence. Maitland, the earliest historian of the city, says, "The situation of Edinburgh plainly shows that its origin is owing to the castle," and from its standing in St Cuthbert's parish, which surrounds the castle rock, he assumes that the first settlement was in the low ground to the north-west. From this a road ancestrally led up past the Well-House Tower, along the northern slope of the Castle Hill. By this access Queen Mary and other royal visitants rode up to the castle on various public entries, and then returned through the town, by way of the High Street and Canongate, to Holyrood. Symon of Durham, under the date 854 A.D., includes Edinburgh among the churches and towns of Northumbria within the bishopric of Lindisfarne, and this is supposed to refer to the church of St Cuthbert. But the first erection of the Magdalen fortress, or "Maiden Castle," on the summit of the rock, must have tempted the natives of the district to seek the protection of its defences. Hence at an early period a hamlet grew up along the ridge which slopes from the castle rock towards the valley at the base of Salisbury Crags, distinct from the Kirk-town of St Cuthbert. In the reign of Malcolm Canmore the Castle of Edinburgh included a royal palace. There his pious queen, Margaret, the grand-niece of Edward the Confessor, died in 1093. It continued to be a royal residence during the reigns of her three sons, and hence the first rapid growth of the upper town may be referred to the 12th century. The parish church of St Giles is believed to have been erected on its present site in the reign of Alexander I, about 1110, and the huge Norman keep of the castle, built by his younger brother, David I., continued to be known as David's Tower till its destruction in the siege of 1572. Before his accession to the Scottish throne, David I. had been earl of Huntingdon, having acquired that manor and earldom in England by his marriage with Matilda the heiress of Wallerof, earl of Northumberland. He consequently frequented the English court, and became familiar with the military and ecclesiastical architecture introduced by the Anglo-Norman kings; and soon after his accession to the Scottish throne he founded the Abbey of Holyrood, which from an early date served the Scottish court as a dwelling or guest-house. But notwithstanding the attractions of the abbey and the neighbouring chase, the royal palace continued for centuries to be within the fortress, and there both the Celtic and Stuart kings frequently resided. Edinburgh was long an exposed frontier town with a territory annexed to Malcolm II. about 1020; and even under the earlier Stuart kings it was still regarded as a border stronghold. Hence, though the village of Canongate grew up beside the abbey of David I., and Edinburgh was a place of sufficient importance to be reckoned one of the four principal burghs as a judicatory for all commercial matters, nevertheless, even so late as 1450, when it became for the first time a walled town, it did not extend beyond the upper part of the ridge which slopes eastward from the castle rock. But the mural defences of the town were an evidence of wealth and growing prosperity; and no sooner was it surrounded with protecting walls than its rapid increase led to the growth of an extensive suburb beyond their limits. The other three royal burghs associated with Edinburgh were Stirling, Roxburgh, and Berwick, and their enactments form the earliest existing collected body of the laws of Scotland. But the determination of Edinburgh as the national capital, and as the most frequent scene of parliamentary assemblies, dates from the assassination of James I., in 1437. Of the thirteen Parliaments summoned by that sovereign, only one, the last of them, was held at Edinburgh. But his assassination that same year, in the Blackfriars' monastery at Perth, led to the abrupt transfer of the
accommodation for the increasing population was secured by crowding buildings on every available spot within the protection of the walls, displacing the earlier structures by lofty piles of building within the straightened area, and projecting from them overhanging additions of timber. By those means the northern and southern slopes of the ridge along which the main street of the old town was formed were crowded with the picturesque alleys and closes which contributed so much to the peculiar aspect which the ancient city still retained when in 1808 Scott thus pictured it —

"Such dainty grandeur clothed the height,
Where the huge castle holds its state,
And all the steep slope down,
Whose ruddy back heaves to the sky,
Riled deep and many, close and high,
Mines own romantic town."

Within this ancient civic area stand the collegiate church of St Giles—for a time the cathedral of the diocese of Edinburgh,—the Parliament House and law courts, and the civic Council Chambers. Here also in earlier years of the present century stood the old Tolbooth, or Heart of Mid-Lothian, and other buildings of note, including mansions of the Scottish nobility, and even of royalty. But it forms a mere historic nucleus of the modern city, which for a century past has been extending over the neighbouring heights, northward towards the ancient sea-port of Leith, and southward and westward to the lower slopes of the Pentland Hills. The area included within the parliamentary boundary extends to 4179 acres, or 64 square miles; but, owing to its singularly irregular site, while the lower parts of the city stand little more than 100 feet above the level of the sea, the higher parts rise in some places to 250 feet, and the summit of the castle rock is 383 feet above the sea.\footnote{1} Within the same civic

---

\footnote{1} The extensive building operations engaged in by the corporation at the beginning of the century were the main cause of the insolvency of the city in 1835, when the property of the corporation was valued...
area, and entirely surrounded and in part encroached on by its streets, is the Calton Hill, occupied by the Royal Astronomical Observatory, the floor of which stands at a height of 349 feet above the sea; and beyond the narrow valley, in which the Canongate and the Palace of Holyrood lie, Arthur's Seat and Salisbury Craggs rear their loftv cliffs in boldly picturesque outline, the highest summit rising to the height of 822 feet, and affording a magnificent prospect over land and sea. Bridges connect the different ridges on which the city is built, with crowded thoroughfares underneath. Many of the public buildings occupy lofty terraces, and thereby show to greater advantage than their architectural designs would otherwise secure for them. The valley between the Old and the New Town, and the slopes of the castle rock, are laid out as public gardens; and the Calton Hill and Arthur's Seat furnish promenades and carriage drives of unequalled variety and beauty as the public parks of a large city. Fine white freestone abounds in the immediate neighbourhood, and furnishes abundance of the best building material; while the hard trap-rock, with which the stratified sandstones of the coal formation have been extensively broken up and overlaid, supplies good materials for paving and roadmaking.

Thus on a locality seemingly ill-adapted for the site of a great city, there has gradually arisen one which compares to advantage with the most picturesque and beautiful among the capitals of Europe. Sir David Wilkie came to it in 1799 fresh from a Fifeshire maus, to begin the studies in the Edinburgh school of design which ultimately secured for him his high fame as an artist. When he returned to it in later years, familiar with all that European art had to disclose, he thus gave utterance to his matured impressions:—

"What the tour of Europe was necessary to see elsewhere I now find congregated in this one city. Here are all the beauties of Prague and of Salzburg, here are the romantic sites of Como and Tivoli; and here is all the magnificence of the admired bays of Genoa and Naples. Here, indeed, to the poetic fancy may be found realized the Roman Capitol and the Great Saloon of the Quirinal, the temple of Juno, the Palatine, and all the wonders of the Grecian Acropolis."...—

The name of Edinburgh is a memorial of the intrusion of a new people, when, in the beginning of the 7th century, the race of Ida reared the fortress of Edinburgh to the height of 196,979. But the narrow bounds of the ancient city and the burgh of Canongate, with the main street extending along the height of the slope from the Castle to Holyrood Palace, and the Cowgate as the only other thoroughfare admitting of the passage of wheeled carriages. Hence the vehicle in general use was the sedan chair, by means of which the Scottish nobility and gentry passed fashionable visits in the narrow wynds of their ancient capital, and proceeded in full dress to the assemblies and balls, which were conducted with the most aristocratic exclusiveness in an alley on the south side of the High Street, which still bears the name of the Assembly Close.

Beyond the walls of the ancient city lay the burghs of Edinburgh during the present century has been remarkable in many ways. In 1801 the population, including the Canongate and other extra-mural suburbs, but exclusive of Leith, was 106,544; in 1871 it had risen to 198,379. But the characteristics of the city and its population are peculiar. From an early date the special associations with the national literature have been identified with the ancient capital Edinburgh, the contemporary of Chaucer, was archdeacon of Aberdeen; and the royal author of the "King's Quair" is chiefly associated with Edinburgh, but in the following reigns Eildon Hill became the favourite residence of the Scottish kings. One of the foremost charges against James III. was that he preferred the society of artists and musicians to that of the rough barons of his court. Under the patronage of his son, the printing press was first set up at Edinburgh in 1507. At the court of Holyrood, so long as James IV. reigned, the rivalry of rank and genius involved no conflict. Of the three great poets of the reign, Dunbar is believed to have been a grandson of the earl of March; Walter Kennedy was a younger son of the first Lord Kennedy; Gawin Douglas the third son of the earl of Angus; and Dunbar enumerates six or seven other literary contemporaries. In his "Remonstrance to the King," he notes among the servitors of his royal master glaziers, wrighters, goldsmiths, lapidaries, apothecaries, painters, and printers: and some of his own poems appear to have been among the first works issued from the Edinburgh press by the Scottish Caution, Walter Chapman. Gawin Douglas, the author of the "Palace of Honour," and the translator of Virgil, was provost of the collegiate church of St Giles; and Rovell, another literary contemporary named by Dunbar in his "Lament for the Makaris," is believed to have been provost of the neighbouring collegiate church of Corstorphine. In the following reign Sir David Lindsay was the leader among the literary men of the Scottish capital; and as one of the members of the Council of the Three Estates was enacted in the presence of the court, at Greenwich, a natural amphitheatre on the north-
EDINBURGH

West side of the Calton Hill, which appears to have been the favourite titling ground, and general arena for public displays,—including even the burning of heretics and witches.

The names of Knox (died 1572), Buchanan (1532), Alexander Montgomery (1605), Drummond of Hawthornden (1649), Allan Ramsay (1715), Smollett (1771), Ferguson (1774), and Burns (1795), carry on the literary associations of the Scottish capital nearly to the close of the 18th century, when various causes combined to give them a new significance and value. In the later years of the 18th and the beginning of the 19th century the university of Edinburgh was distinguished by teachers who gave it a prominent rank among the European schools of science and letters; while members of the legal faculty disputed with them in friendly rivalry. Gregory (died 1701), the Monroes (the elder 1767, the second 1817), Cullen (1790), Black (1799), Playfair (1819), Dugald Stewart (1828), and Leslie (1832), all figure among the professors of the university; while David Hume (1776), Adam Smith (1770), Robertson the historian (1793), Henry Mackenzie (1851), and others of the same literary circle gave ample range to its intellectual triumphs. To this succeeded the era of Marmion and The Lady of the Lake, followed by the Waverley Novels, and Blackwood's Magazine and the Edinburgh Review, when Scott, Brougham, Jeffrey, and Chalmers gave the character to the literary society of Edinburgh which won for it the name of Modern Athens. To this the actual correspondence of its site to that of Athens no doubt also contributed. Various travellers have noted the resemblance between the distant view of Athens from the Aegean sea, and that of Edinburgh from the Firth of Forth. The popular recognition of this unfortunately tempted the citizens to aim at a reproduction of the Parthenon on the summit of the Calton Hill, in commemoration of Wellington and his brothers in arms, by whom the victory of Waterloo was made the harbinger of peace to Europe. The abortive scheme, as an incompletely projected, undesignedly reproduces the ruin of the ancient Acropolis.

Literary taste and culture still characterize Edinburgh society; but—apart from the exceptional influences of eminent genius—the causes which largely contributed to give it a special character no longer exist. In Scott's early days a journey to London was beset with difficulties and even dangers; whereas railways have now brought it within a few hours' distance, and Scottish artists and literary men are tempted to forsake Edinburgh for the great centre of all national activities. Nevertheless, the influence of the past still survives in many ways. Edinburgh is not a manufacturing city, but retains even now something of the character of the Scottish capital, as the resort of those whose means enable them to enjoy in ease and comfort its social amenities, without indulging in the costly gaieties which a London season involves. The supreme courts of law hold their sittings in Edinburgh, and still retain some of the most characteristic features impressed on them when remodelled by James V. in 1532. The Court of Session has the lord president as its head; and the High Court of Justiciary is presided over by the lord justice-general and the lord justice-clerk. The judges, as senecors of the College of Justice, have also the title of lord, not infrequently coupled with that of their landed estate—as Fountainhall, Hailes, Momboddi, Woodhouses, or Colmonay; and the advocates and writers to the signet—as the two leading branches of the Scottish legal profession are styled,—help to give a legal ton to the society of the Scottish capital.

The university, with the medical schools and other educational institutions, have long added to the attractions of Edinburgh. As a school of art it has also required a special character; and the names of Runciman, Nqmyth, Raeburn, Wilkie, Allan, M'Colloch, Watson Gordon, Harvey, and Drummond (without referring to living painters and sculptors) are all familiar, and some of them eminently distinguished in art. A school of design was established at Edinburgh in 1750 by the Honourable Board of Trustees for Manufactures, at which Raeburn, Wilkie, Allan, and other leading Scottish artists, along with many others, have also obtained their preliminary training. With its aid the application of art to manufacturing design and decoration has received an important stimulus. Steel and wood engraving have also largely benefited by the same facilities; and this in its turn has aided in fostering the printing press as a special branch of trade for which Edinburgh has long been celebrated. In early days the names of Chapman, Millar, Bassandyne, Charters, Hart, Watson, and Ruddiman figure among its celebrated typographers; and more recent enterprise has added to the reputation of the Edinburgh press.

But although a large unemployed population, in close proximity to a coal-field and to the fertile Lothians, and with the command of the chief seaport of the east of Scotland, gives a stimulus to important industries, the Scottish capital lays no claim to rivalry with Glasgow or Dundee as a manufacturing town. The unique beauty of its site, and the abundance of fine building material, while they have fostered the desire for developing its architectural features have begotten a disinclination to encourage such manufactures as would tend to interfere with the amenities of the city. The anxiety with which these are guarded commands the sympathy of all classes of the community. The distinctive character of the New Town is all the more effective from the contrast which it thus presents to the older districts of the city. In most of the old historical cities of Europe the stranger recalls the contrast as he proceeds from modern to older districts; but in Edinburgh he can look down on the city from the castle, the Calton Hill, or Arthur Seat, and see on the whole spread out like a map before him; or, as he traverses the beautiful terrace of Princes Street, adorned with statues, monuments, and public buildings, he looks across the fine paler grounds in the intervening valley to the quaint old town with its still older castle.

The improvements effected on the Old Town during the past forty years, while they have swept away many unsightly irregularities of the sites occupied by ancient buildings, have also largely benefited by the same facilities. The帅metrical regularity of the New Town is kept in view. The predominant character of the former is a seemingly less picturesque features, resulting from the extreme irregularities of the sites occupied by its most prominent buildings on the abrupt slopes of the ridge which is crowned by the ancient fortress. The symmetrical regularity of the New Town is all the more effective from the contrast which it thus presents to the older districts of the city. In most of the old historical cities of Europe the stranger recalls the contrast as he proceeds from modern to older districts; but in Edinburgh he can look down on the city from the castle, the Calton Hill, or Arthur Seat, and see on the whole spread out like a map before him; or, as he traverses the beautiful terrace of Princes Street, adorned with statues, monuments, and public buildings, he looks across the fine paler grounds in the intervening valley to the quaint old town with its still older castle.

The improvements effected on the Old Town during the past forty years, while they have swept away many unsightly historical remains, have on the whole resulted in a more effective development of its picturesque features. During the same period the New Town, and the still more recent extensions to the west and south, have been carried out with a careful eye to the general result; and alike in the Old and the New Town the advantageous sites of the chief public buildings largely contribute to their architectural effect.

The Castle.—The central feature of Edinburgh is the castle, which includes structures of very diverse dates. The oldest of its buildings, occupying the very summit of the rock, is St. Margaret's Chapel, an interesting relic, belonging at latest to the reign of Queen Margaret's youngest son, David I., and by some good authority believed to be the actual chapel in which the queen of Malcolm Canmore worshipped. Next in interest are the ancient hall and other remains of the royal palace, which form a fine quadrangle styled palace yard, and occupy the summit of the rock towards the south. These buildings include the apartments occupied by the regent, Mary de Guise, and
Edinburgh

her royal daughter, Queen Mary, and the room in which James VI. of Scotland and I. of England was born. Here also is the Crown Room, in which are deposited the Scottish regalia, or "The Honours of Scotland," as they are called, along with a beautiful sword of state presented to James IV. by Pope-Julius II., and the jewels restored to Scotland on the death of Cardinal York, the last of the Stuarts.

The arsenal, a modern building on the west side of the castle rock, is capable of storing 30,000 stand of arms. In the armoury a display of arms of various dates is made, and on the Argyll battery, immediately to the south of St Margaret's Chapel, stands a huge piece of ancient artillery, called Mons Meg, of which repeated mention is made in Scottish history.

Holyrood Palace, the venerable abode of Scottish royalty, was originally an abbey of canons regular of the rule of St Augustine, founded by David I. in 1128. The ruined nave of the abbey church still retains portions of the original structure. Conjoined to this is a part of the royal palace erected by James IV. and V., including the apartments occupied by Queen Mary, and the scene of the murder of Rizzio in 1566. The abbey suffered in repeated English invasions. It was sacked and burned by the earl of Hertford in 1544, and again pillaged and left in ruin by the same invader in 1547, almost immediately after the accession of Edward VI. to the English throne. In a map of 1544, preserved among the Cotton MSS., in the British Museum, the present north-west tower of the palace is shown standing apart, and only joined to the abbey by a low cloister. Beyond this is an irregular group of buildings, which were replaced at a later date by additions more in accordance with a royal residence. But the whole of this later structure was destroyed by fire, while in occupation by the soldiers of Cromwell, in 1650; and the more modern parts of the present building were commenced during the Protectorate, and completed in the reign of Charles II. by Robert Mylne, in accordance with a design of Sir William Bruce of Kinross. They include the picture gallery, 150 feet in length, famous for its fanciful array of 106 mythical portraits of Scottish kings, the reputed descendents of King Fergus I., but also adorned with a remarkable triptych, painted about 1464, containing portraits of James III. and his queen, Margaret of Denmark, and believed to have formed the altar-pieces of the collegiate church of the Holy Trinity, founded by the widowed queen of James II. in 1463, and only demolished in 1848. The picture gallery is interestingly associated with festive scenes during the banquet given by Prince Charles Edward in 1745; and in it the elections of representative peers for Scotland take place. The exiled Comte d'Artois, afterwards Charles X. of France, had apartments granted for the use of himself and the emigrant nobles of his suite, on their escape from the first French Revolution, and they continued to reside in the palace till August 1799. When driven from the French throne by the revolution of 1830, the same unfortunate prince once more found a home in the ancient palace of the Stuarts. In the interval between these two visits it was graced by the presence of George IV. in 1822, and he has been repeatedly occupied for brief periods by Queen Victoria and the Prince Consort.

A beautiful fountain, the design of which is a restoration of the ruined fountain in the quadrangle of Linlithgow Palace, stands in the centre of the outer court of Holyrood, and is of the interest excited by Prince Albert in the ancient Scottish palaces.

The Parliament House, in which the last assemblies of the Scottish estates took place, until the dissolution of the Parliament by the Act of Union of 1707, has ever since been set apart as the place of meeting of the supreme courts of law. The great hall, with its fine open-timbered oaken roof, under which the last Scottish Parliament assembled still stands, and forms the ante-room of the advocates and other practitioners, and of their clients, during the sessions of the supreme courts. But the surrounding buildings, including the court-rooms, the Advocates' and the Signet Libraries, are all modern additions. The Advocates' Library is the largest and the most valuable library in Scotland. It was founded in 1682, at the instance of Sir George Mackenzie, king's advocate under Charles II., and then dean of the faculty, and has been augmented by important gifts. It is regarded with just pride as the national library, and is one of the five libraries entitled by the Copyright Act to receive a copy of every work printed in Britain. The number of volumes now included in the collection is estimated to amount to 260,000. The Library of the Society of Writers to the Signet contains upwards of 50,000 volumes, and, although more private in its character, it has always been available for research by literary students.

The General Register House for Scotland, which stands at the east end of Princes Street, is an important adjunct to the supreme courts; and, in its ample provisions for the registry and safe-keeping of all deeds and judicial records, it compares favourably with the system in vogue in England. Not only is there adequate accommodation, in fire-proof chambers, for all Scottish title-deeds, entail, contracts, and mortgages, and for general statistics, including births, deaths, and marriages, but there also are deposited all the ancient national records, the full historical value of which is only now beginning to be generally appreciated.

The Royal Institution, a fine structure of the Grecian Doric order, surmounted by a colossal statue of the Queen, executed in stone by Sir John Steell, furnishes official accommodation for the Board of Trustees for Manufactures, and the Board of Fishery, and also for the School of Art and Status Gallery of the Royal Institution, the Museum of National Antiquities, and the libraries and public meetings of the Royal Society and the Society of Antiquaries of Scotland. This handsome building is the centre of varied intellectual activity, in artistic culture and design, scientific, historical, and archaeological research, as well as in the practical application of the fine arts, and of the newest disclosures in science, to the manufacturing and trading interests of the kingdom.

Among those the National Museum of Antiquities claims special attention. The Society of Antiquaries of Scotland was founded in the year 1780 by a body of noblemen and gentlemen, who held their first meetings at the house of the earl of Buchan; and almost immediately after its foundation they devoted themselves to the formation of an Archæological Museum. The history of the early years of the society is a curious commentary on the manners of the Scottish capital a century ago. With the duces of Montrose and Argyle, the earls of Buchan, Bute, Fife, and Kintore, and many of the leading Scottish gentry among its active members, a suitable hall secured for the meetings of the society in the Cowgate was successively exchanged for others in Webster's Close, and Gourlay's Close, Lawnmarket—the reason assigned for abandoning the latter being that the alley was too narrow to allow of the members reaching the society's hall in their sedan chairs. After passing through various vicissitudes, and occupying more than one hall in the New Town, it was found that the collections of the society had attained to a magnitude and value which rendered it no longer possible for a private society to do justice to them. Archæological investigations,
moreover, have now come to occupy a no less important relation to the researches of science than to the study of history; and in many of the capitals of Europe similar collections are promoted as objects of national importance. Negotiations were accordingly entered into with the Government in 1849 and subsequent years, which resulted in the appropriation of the galleries in the Royal Institution, formerly devoted to the exhibitions of the Royal Scottish Academy, to the reception of the collections of the Society of Antiquaries of Scotland as a National Museum of Antiquities. The council of the society, with the addition of two members of the Board of Trustees as representatives of the Crown, continue to have the charge of the collections, which are open to the public, like the British museum and other national collections. The museum is specially rich in Scottish antiquities, illustrative alike of prehistoric archæology, of Roman, Celtic, and Teutonic remains, and of medieval civil and ecclesiastical art; and its native and foreign collections of primitive antiquities are arranged with a view to illustrate modern archæological science, by the comparative classification of numerous examples of primitive flint, stone, and bronze relics, sepulchral pottery, implements and weapons, and of personal ornaments of gold, silver, and bronze. The society publishes its proceedings annually, and from time to time issues its transactions, embodying the more important historical and archæological treatises submitted to its meetings, in the quarto volumes of the Archæologia Scotia.

The Royal Society of Edinburgh was incorporated by royal charter in 1783, for the encouragement of philosophical inquiry and scientific research. Its extensive library and other collections are accommodated in the apartments occupied by it in the Royal Institution buildings; and its proceedings and transactions are now voluminous, and embody many important scientific papers.

The Royal Scottish Academy of Painting, Sculpture, and Architecture, was instituted in 1826, and incorporated by royal charter in 1838, on the model of the Royal Academy of London. Subsequent to the completion of the Royal Institution buildings, the central range of the galleries was appropriated to the annual exhibitions of the Academy; but in August 1850 Prince Albert laid the foundation-stone of the National Gallery, a building exclusively devoted to the promotion of the fine arts in various ways, including the accommodation of the Royal Scottish Academy, and which has greatly contributed to the architectural beauty of the city. The low valley, or ravine, which separates the Old from the New Town, is not only spanned by the North and Waverley Bridges, but is also crossed midway by a huge earthen viaduct, formed by depositing the materials excavated for the foundation of the houses erected on the neighbouring terraces of Princess Street. This, which long formed an unsightly blemish, was at length utilized for the improvement of the city, as the site of the National Institution building. But there still remained in the rear a huge expanse styled the Earthen Mound, cumbered with temporary buildings, and an eyesore to all who appreciated the amenities of the general view. The property of this as a building site was acquired by the Board of Trustees under an Act of Parliament, which vested it, and the buildings erected thereon, in the Board, subject to the Lords Commissioners of the Treasury; and in 1854 the new galleries were completed. The building is of the Greek Doric order, thereby pleasantly contrasting with the more massive Doric of the Royal Institution building; and the view of the two, as seen from East Princes Street, grouping together with the Castle, the Free Church College, and the masses of the Old Town buildings rising behind, is singularly striking and effective. The National Gallery provides for the public display of a fine national collection of paintings and sculpture, acquired by purchase and bequest, for the annual exhibitions of the Royal Scottish Academy, and for the Life Academy and other schools specially designed for the advancement of the fine arts in Scotland.

The University of Edinburgh was founded in 1582, by a royal charter granted by King James VI., and its rights, immunities, and privileges have been remodelled, ratified, and extended at various subsequent periods. In 1621 an Act of the Scottish Parliament ratified to the university of Edinburgh all rights and privileges enjoyed by other universities in the kingdom, and those were renewed under fresh guarantees in the Treaty of Union between England and Scotland, and in the Act of Security. Important changes have since been made on the constitution of the university by an Act of the British Parliament passed in 1858. But while the college, as such, bears the name of the College of King James, or King's College, and James VI. is spoken of as its founder, it originated in the liberality of the citizens of Edinburgh. William Little of Craigmullar, and his brother Clement Little, advocate, along with James Lawson, the colleague and successor of Knox, may justly be regarded as the true founders of the college. In 1580 Clement Little gave all his books, amounting to 300 volumes, for the beginning of a library, and this was augmented by other valuable benefactions, one of the most interesting of which was the library of Drummond of Hawthornden, the friend of Ben Jonson—a collection rich in choice specimens of our rarer early literature. The University Library now contains about 139,000 printed volumes, and above 700 volumes of MSS., many of which are of great interest and value.

The buildings of the university occupy the site of the ancient collegiate church of St Mary in the Field, or the Kirk of Field, as it was familiarly termed. The present structure is a classical building, inclosing an extensive quadrangle. The older parts of it, including the east front, are from the design of Mr Robert Adam; but his plans were revised and modified with great taste by Mr W. H. Playfair, with a view to the completion of the building; and the whole is now finished, with the exception of a cupola designed to surmount the east front, for which the requisite funds have been bequeathed to the university. The edifice affords accommodation for the lecture rooms in the four faculties of arts, law, medicine, and theology, and for the museums and library. But although entirely reconstructed on a greatly enlarged scale during the present century, they have already proved to be inadequate for the requirements of this celebrated school of science and letters; and extensive new buildings are now in progress at Tavistock Row, designed to accommodate the departments of science and medicine, and to leave the older building exclusively for the departments of arts, law, and theology. The new buildings will accordingly include a university convocation hall, class-rooms, laboratories, dissecting rooms, and museums.

In connection with this, the Royal Infirmary is also in progress of completion, on a new site, and on a greatly enlarged scale, with operating theatre and other requirements in connection with the medical school, and with all the most modern improvements in the arrangement and construction of hospitals. For this a site nearly adjoining to that of the new college buildings, previously occupied by George Watson's Hospital, has been selected. It embraces a large area between the Heriot's Hospital grounds and the Meadows, and separated by the fine avenue of the Meadow Walk from the new medical schools. By this means the important requisites of free air and the immediate vicinity of extensive pleasure grounds are secured; and thus the primary object of the infirmary as a benevolent institution for ministering to the wants of those afflicted with disease,
or suffering from injuries, is efficiently combined with its indispensable uses as a school for clinical instruction and practical training in the healing art.

The Royal Botanical Garden is another important adjunct to the university as a school of science. The professor of botany is regius keeper of the garden; but its special requirements necessitate its removal from the crowded centre of the city. It has accordingly undergone four successive changes of site since its foundation in 1670 by Sir Andrew Balfour and Sir Robert Subbald. It now occupies a fine area of 27 acres on the north side of the city, in Inverleith Row. This is carefully laid out with a special view to botanical instruction. It includes a herbarium and palm houses, with an extensive range of botanic gardens, a museum of economic botany, a lecture room, and other requisites for the students of botany who attend here the lectures of the professor during the summer term.

The Royal Observatory, which has already been referred to as one of the arts of the Calton Hill, also constitutes an important adjunct to the university. The astronomer royal for Scotland holds along with that office the professorship of practical astronomy.

Museum of Science and Art.—One other important institution of practical instruction, in intimate connection with the university, is the Museum of Science and Art, situated immediately to the west of the university building, and in direct communication with it. The first keeper of the museum, Dr George Wilson, was also professor of technology in the university, but the chair has not been filled since his death, though his successor in the charge of the museum delivers lectures from time to time in the large lecture room in the east wing of the building, which is capable of accommodating about 800 sitters. The Museum of Science and Art embraces not only the objects of science included in the departments of geology, mineralogy, paleontology, and natural history, as well as other allied sciences, but also of industrial art, and of the raw productions of commerce, illustrative of nearly all the chief manufactures of Great Britain, and of many foreign countries.

Royal College of Surgeons.—The museum and lecture rooms of the Royal College of Surgeons are accommodated in a handsome classical building in Nicolson Street, in the immediate vicinity of the university buildings. The College of Surgeons is an ancient corporate body, with a charter of the year 1552, and exerts the powers of instructing in surgery and of giving degrees. It also give lectures on the various branches of medicine and science requisite for the degree of doctor of medicine, and those extra-academical courses are recognized, under certain restrictions, by the university court, as qualifying for the degree. The museum contains a valuable collection of anatomical and surgical preparations adapted to the advancement of the study of surgical science.

Royal College of Physicians.—The Royal College of Physicians is another learned corporate body, organized as such, with special privileges by a charter of incorporation granted to them by Charles II. in 1651. The meetings of the body take place in the hall, a handsome building on the terrace overlooking the Queen Street Gardens, where they have a valuable library and a museum of materia medica. But the college as a body takes no part in the educational work of the university.

The three older Scottish universities of St Andrews, Glasgow, and Aberdeen, founded in the 15th century, by the authority of papal bulls, and derived their original endowments chiefly from the liberality of munificent ecclesiastics, who had large revenues and church property at their disposal. They represent a part of the grand conception of the 15th century, which aimed at organizing the learning of the age into local branches of one university system, embracing the whole scholarship of Christendom, and recognizing the graduates of all universities as members of one corporate brotherhood, co-extensive with the Christian world. The Scottish university system still differ from those of Oxford and Cambridge in perpetuating some curious relics of this combined national university system.

The first conception of the University of Edinburgh is also due to a learned Scottish ecclesiastic, Robert Kirk, bishop of Orkney, a favourite councillor of James V, who died at Dunger-Arms in 1548, as it is believed from poison, when on his way home, after fulfilling his duties as one of the commissioners of Scotland to the Dauphin of France. He left a bequest of 8000 marks towards the founding of a college at Edinburgh, and is stated by the historian of the family of Sutherland to have directed a much larger sum for the same purpose, but it was diverted by the Earl of Morton to his own use. The above-named bequest was only recovered after long delay, when, in 1581, it was appropriated to the purchase, from the provost of the Kirk of Field, of the grounds now occupied by the university buildings. The circumstances attendant on the death of this first benefactor of the University remind us of the ecclesiastical changes already in progress in the 16th century. The actual foundation of the University of Edinburgh dated subsequent to the Reformation, and it is honourably distinguished among the national universities of Great Britain as the vestiges of the Christian Church.
Institution, of which Mr Thomas Carlyle is president. The lending library of this institution is extensive and valuable, and its annual winter courses of lectures are of a high character, and command great popular interest. The Edinburgh Literary Institute, formed on a nearly similar basis, has its building in South Clerk Street, in the southern part of the city.

Schools.—The public seminaries of Edinburgh, including the private schools and other charitable foundations chiefly directed to the training and education of youth, are upon a very liberal scale. The High School of the burgh dates its existence from an early period in the 16th century. The Burgh Record, under date March 12, 1554, contains an order for the building of the grammar school on the east side of the Kirk of Field Wynd. At a later date, and down to the present century, it occupied the site of the Blackfriars' monastery founded by Alexander II. in 1230. But in the year 1825 the foundation stone was laid of the beautiful classical building which now occupies a prominent site on the southern slope of the Calton Hill. It was originally, and till a comparatively recent date, a purely classical school, but it now furnishes systematic instruction in all the departments of a liberal and commercial education, including the ancient and modern languages, the natural sciences, mathematics, &c.

The Edinburgh Academy, which was established in 1824, and incorporated by royal charter of George IV., is a proprietary school under the superintendence of a board of directors elected by the subscribers. It is arranged into two divisions, the classical and the modern school, for the senior classes. It has established a high character for its classical training, and has already taken an honourable rank among the public schools of Great Britain, by the distinctions achieved by its pupils both at the English and Scottish universities.

Charitable Foundations.—Foremost among the charitable foundations for the education and training of youth is George Heriot's Hospital, founded by the jeweller of James VI. of Scotland and I. of England, who at his death in 1624 left his estate in trust to the magistrates and ministers of Edinburgh for the maintenance and education of poor fatherless boys of freemen of the city. The building erected for the purposes of the charity is a noble quadrangular edifice, enriched with the elaborate details of the transitional style of domestic architecture of the earlier Stuart kings of England. It occupies a commanding site on the summit of a ridge known of old as the High Riggs, lying between the Grassmarket and the Meadows, and forms a striking feature in the view of the city from various points. 180 boys are maintained on the foundation, 120 resident, and 60 non-resident. Those among them who give proof of diligence and ability are afterwards maintained during a full course of four years at the university; and those who are apponticed to trades are also provided with funds for five years, amounting in all to £50 sterling, with an additional £5 on proof of good behaviour at the close.

The popular character of Heriot's Hospital, and the effective architecture of its building, have largely influenced the disposition of later charitable bequests in Edinburgh, somewhat to the detriment of the university. Following the example of the jeweller of King James VI., successive benefactors have founded George Watson's Hospital, the Merchant Maiden Hospital, the Trades' Maiden Hospital, the Orphans', John Watson's, Donaldson's, and Stewart's hospitals—all more or less modelled on the original foundation.

Several of their buildings are possessed of considerable architectural beauty, foremost among which is Donaldson's Hospital, the founder of which amassed a large fortune as a printer, and bequeathed nearly the whole of it in trust for the erection and endowment of a hospital for the maintenance of poor boys and girls. The trustees have taken advantage of the liberty of choice permissible under the will of the founder to choose half of the children admitted to the hospital from the class of the deaf and dumb. The building has accommodation for 300 children. In 1877 it contained 214, of whom 120 were boys and 94 girls. Of those 70 of the former and 45 of the latter were deaf and dumb. Experience has thus far tended to show that the constant intercourse between the deaf and dumb and their more fortunate companions exercises a beneficial influence on both.

George Watson's Hospital, founded by the bequest of another citizen in 1733, and the Merchant Maiden Hospital, founded so early as 1605, were designed to extend to the sons and daughters of merchants of Edinburgh similar advantages to those which the Heriot's Hospital secured for its pupils. The Trades Maiden Hospital provided for burgers' daughters, and John Watson's, Daniel Stewart's, and other similar institutions provided in like manner for the maintenance and education of poor children of various classes. But the multiplication of such charities threatened to outgrow the legitimate wants of the community, and needlessly to withdraw many children from the healthful influences of home training. Hence a growing feeling of the abuses of the system, at the very time when the revenues of Heriot's Hospital were greatly increased in consequence of the site being transferred to the New Town over its lands, at length led to an application to Parliament for power to modify the disposition of the surplus revenue by the Act thus obtained the governors of that institution were empowered to expend such surplus funds in erecting and maintaining elementary schools for the free education of poor children of deceased burgesses and freemen, and general of the children of poor citizens of Edinburgh. There are now eighteen of those Heriot foundation schools, in different parts of the city, divided into the two classes of juveniles and infant schools, giving free instruction for five years, and, in certain cases of extreme poverty, also a sum of money in lieu of maintenance, to 4490 boys and girls.

The example thus set has been followed by the governing bodies of other similar institutions. The Merchant Company, as trustees of the George Watson's, Merchant Maiden, Gillette's, and Stewart's charities, taking advantage of powers given by the Endowed Institutions (Scotland) Act, obtained power to convert the George Watson's Hospital into a school; and since then, they have sold the building and grounds to the corporation of the Royal Infirmary, and the New Infirmary is now in progress on the site. The Edinburgh Merchant Company's Schools now include the George Watson's College-Schools, in which ample provision is made for furnishing a liberal education for boys, qualifying them for commercial or professional life, for the civil service, and for entering the university. Bursaries are also offered for competition, which secure a free enjoyment of the entire course of studies to the successful competitors, and furnish the sum of £25 annually, for four years, after leaving the schools. A similar institution provides corresponding advantages for girls; and the Edinburgh Educational Institution, or Ladies' College, in like manner furnishes a high-class education in the ancient and modern languages, mathematics, the natural sciences, music, and other more strictly feminine accomplishments; and bursaries and other prizes, of like value to those offered for competition in the College Schools, are placed within reach of the ablest and most diligent female students.

Experience has, therefore, amply confirmed the wisdom of the course thus pursued in the readaptation of this class of charities to the wants of the age; and the example of Edinburgh is likely to influence other cities where similar endowments are, in some cases at least, very partially turned to useful account.

Edinburgh is otherwise well provided with both public and private schools, to which pupils resort, not only from many parts of the kingdom, but from the colonies. The Fettes College was apparently designed by the terms of the will of its founder, Sir William Fettes, to correspond nearly to Heriot's Hospital. The trustees have so far fulfilled that idea as to establish a college for boys after the great public schools of England, and designed to furnish a liberal education in the fullest sense of the term. The college building which has been erected at Comely Bank, the estate of the founder, on the north side of Edinburgh, is a structure of an imposing and stately character in the semi-Gothic style of architecture prevalent both in France and Scotland in the 16th century.

The Church of Scotland Training College, the Free Church Normal School, Merchiston Academy, occupying
the antique tower of Napier, famous as the inventor of the logarithms, and the Watt Institution and School of Arts, all merit notice among the more important educational institutions; and under the Edinburgh School Board efficient schools are now in operation in various districts of the city, mostly lying beyond the range of the Herold's schools.

Charities.—Among the public charities of the city the Trinity Hospital, no longer maintained as a hospital with resident pensioners, now expends its income in pensions of from £10 to £20, to 172 poor burgesses, their wives, or children, not under the age of fifty years. The benevolent branch of the Gillespie's Hospital endowment is similarly administered. The Chalmers' Hospital, founded by George Chalmers in 1836, destined for the reception of the sick and burt, stands on the southern slope of Lauriston, overlooking the Meadows, and at no great distance from the New Royal Infirmary, to which it is a useful adjunct. In addition to these, it may suffice to name the Convalescent House—where, in a pleasant country home near Corstorphine, the convalescents of the Infirmary are transferred from the surgical or fever wards of that hospital to healthful fresh air,—the Royal Hospital for Sick Children, the Home for Crippled Children, the Hospital for Incurables, the Royal Maternity Hospital, along with other kindred institutions. The Royal Asylum for the Insane is at Morningside, on the southern outskirts of the city; and the Royal Blind Asylum, and the Deaf and Dumb Benevolent Society, each provide for the special classes indicated by their names.

Prisons.—The different city prisons are grouped together on the southern terrace of the Calton Hill, styled of old the Dow Craig, so as to form a very striking feature in the general view of the city from various points. They are constructed in a semi-castellated style; and the house of the governor of the jail, built on the summit of a rock overlooking the whole, and on the very edge of a bold perpendicular cliff, looks not unlike one of the old castles familiar to the voyager on the Rhine.

The General Post-Office is the central office for Scotland, alike for postal and telegraphic service, and the building devoted to those purposes is a large and effective structure in the Italian style of architecture, at the east end of Princes Street, directly opposite to the Register Office.

General Assembly of the Church of Scotland.—During the establishment of Episcopacy in Scotland, Edinburgh was the seat of a bishop, and the ancient collegiate church of St Giles rose to the dignity of a cathedral. The annual meeting of the General Assembly of the Church of Scotland at Edinburgh is now the grand public manifestation of the predominance of Presbyterianism as the national church. Annually in the month of May a nobleman, commissioned to act as the representative of the Queen, takes up his abode at the Palace of Holyrood, and proceeds from thence in state to the High Church, and thence to the Assembly Hall on the Castle Hill, as the lord high commissioner to the General Assembly of the national church. The lord provost and magistrates resolutely offer to him the keys of the city. Leves, receptions, and state dinners revive in some degree the ancient glories of Holyrood; and, as the General Assembly of the Free Church and the Synod of the United Presbyterian Church are usually held at the same time, the streets of Edinburgh present a singular aspect to a stranger.

Places of Worship.—The buildings set apart as places of worship by the various denominations include 30 belonging to the Church of Scotland, 29 to the Free Church, 23 to the United Presbyterian Church, 14 to the Episcopal Church, and about 30 others to different religious denominations, including a Jewish synagogue.

St Giles's Church.—Among the buildings dedicated to the worship of the different denominations, the ancient collegiate church of St Giles is the most important, alike in its architecture and its historical associations. The Regent Murray, the marquis of Montrose, and Napier of Merchiston are distinguished among the eminent men interred in the ancient church, by monuments marking their tombs. The choir, which has recently been cleared of encumbering galleries, and tastefully fitted up with oaken stalls, and a fine carved pulpit of Caen-stone, is a beautiful example of the ecclesiastical architecture of the 15th century, and the fine Gothic crown which surmounts the central tower forms one of the most characteristic features in every view of the city. The domes, towers, and spires of the various churches add to the general effect of the city, and in some cases they even present an imposing aspect from their elevated and commanding sites. But none of them is of sufficient importance to invite notice for any special architectural beauty, though several are works of merit. By the bequest of Miss Walker of Coates and Drumbeagh, who died in 1871, funds have been set apart for the erection of a cathedral for the use of the Scottish Episcopal Church. The plans have been prepared by Sir G. Gilbert Scott, in the Early Pointed style of the 14th century, and include a nave, choir, transepts, and chapter-house. If completed according to the approved design, it will be the largest and finest church erected in Scotland, if not in Britain, since the Reformation.

Monuments.—The monuments and statues which adorn the city are of a peculiar character, and contribute to the singular aspect which Edinburgh presents to the eye of a stranger. The fame of Sir George Mackenzie, David Hume, Dugald Stewart, Playfair, Burns, and Scott is commemorated in the case of each by an effective monumental structure dedicated to his memory. Of these the most remarkable is the monument erected by public subscription in memory of Sir Walter Scott, which stands in the eastern division of the Princes Street Gardens. The design, which was furnished by a young architect, Mr W. Kemp, is that of a spiral Gothic cross, of great elegance both in outline and in details. A marble statue of Scott, by Sir John Steell, is placed under the central canopy; and the principal figures of two of Scott's novels in his own handwriting. The Nelson monument, a lofty castellated turret which crowns the highest cliff of the Calton Hill, though of questionable architectural taste, is a striking feature in the general view of the city; and the Melville monument, a graceful and well-proportioned column 136 feet in height, surmounted by a colossal statue of Viscount Melville, first lord of the admiralty under Pitt, rises from the centre of St Andrew Square, and terminates the eastern vista of George Street, with a reproduction, in its proportions and general outline, of the celebrated Trajan column at Rome. Distant half a mile from this, at the west end of George Street, Charlotte Square furnishes a corresponding site for the monument of Prince Albert, from the design of Sir John Steell. A central pedestal, which sustains the equestrian statue of the Prince Consort, has at each of the four angles at its base a group of figures representing different classes of the community paying honour to him; and bas-reliefs, executed, like the statues, in bronze, illustrate characteristic incidents in the Prince's career. George Street is further adorned at the intersection of two of the intermediate streets between St Andrew and Charlotte Squares, with colossal bronze statues by Chandrey of George IV. and Pitt. The beautiful garden terrace of Princes Street, on which the Scott monuments stand, also affords appropriate sites for the statues of Allan Ramsay, John Wilson, and other distinguished Scotchmen; at other prominent points in...
the Old and New Towns are equestrian statues of Charles II., the duke of Wellington, and John, fourth earl of Hopetoun; and also statues of the duke of York, George Melville, etc. The monument to the poet Burns, erected on a prominent site on the southern terrace of the Calton Hill, is in the style of a Greek peripteral temple inclosing a cella designed to form the shrine of a fine marble statue of the poet executed by Flaxman. But it proved to be too confined to afford a satisfactory view of the statue. This has accordingly been replaced by a bust from the chisel of Brodie; and the statue, after being placed for a time in the university library, now forms a prominent feature among the works of sculpture in the National Gallery.

Manufactures.—The principal manufactures may be classed under the following respective heads:—(1) Printing, lithographing, engraving, bookbinding, and type-founding; (2) brewing, distilling, coopering, and manufacture of aerated waters; (3) furniture work, paper-hanging, and coach-building; (4) indigo-rubber work; (5) machinery and brassfounding; (6) tanning; (7) glass work; (8) confec tionery.

The city is supplied with water from various extensive reservoirs formed in the valleys of the Logan Water, the Bavelaw Burn, and the North Esk, in the Pentland Hills, lying to the south of the city. A bold project was started in 1872 for securing an inexhaustible supply by bringing in the water from St Mary's Loch, a beautiful lake about three miles in length, at the head of the Vale of the Yarrow, in Selkirkshire; but the plan met with considerable opposition, and was abandoned for a less comprehensive measure, sanctioned by Parliament in 1874, whereby additional reservoirs have been constructed in the neighbouring valleys, and an adequate supply of water secured for the growing requirements of the city.

The population of the parliamentary borough of Edinburgh amounted in 1851 to 136,294, in 1851 to 160,992, and in 1871 to 196,979 (89,245 males and 107,734 females). In 1877 the population was estimated at 218,729; and the annual value of real property was £1,533,738. The city returns 2 members to parliament, and its corporation consists of a lord provost, 6 bailies, a convener of the trades, a dean of guild, and 32 councillors.

References may be made to W. Marland's History of Edinburgh (1753), Arnot's History of Edinburgh (1789), R. Chamberlain's Traditions of Edinburgh (1834), and D. Wilson's Memorials of Edinburgh in the Olden Time (1846-49).

EDMUND, Sr (c. 1190-1240). Edmund Rich, archbishop of Canterbury, was about the close of the 12th century, at Abingdon, then the seat of a great Benedictine convent. He was one of six children. His father was a rich trader and man of the world, his mother a pious woman, who carried out remorselessly the ascetic conscience of a religious life. She fasted much and slept little, wore a hair chemise and iron stays, and made her household so uncomfortable by her arrangements that her husband, with her consent, retired to a monastery at Eynesham, as likely to be a more enjoyable home. The story of Edmund's birth and early years is strewn with marvel and miracle. Trained by his mother, he caught her ascetic spirit, and became a willing imitator of her self-mortifying ways. At the age of twelve he was sent to a school at Oxford, where he studied diligently, but continued his ascetic exercises. Naturally susceptible in a high degree to the charm of beauty, he nevertheless vowed a vow of celibacy, and espoused himself to the Blessed Virgin Mary. At Oxford he was prostrated by a high fever, so low indeed that she attended him, and by her deherv received the clerical tonsure. Shortly after, his father apparently being dead, he was sent to Paris to study at the university. He was called home to attend his mother on her death-bed; and during the next twelve months he lived in retirement in the convenant of Merion, in Cork. He then returned to Oxford, and at once took an honourable place among the teachers of the university, which he retained for some years. He is distinguished as one of the scholars who introduced the study of Aristotle; and he heartily co-operated with those who were striving to recover for Oxford the popular and prosperity as a place of study which it had recently lost, in consequence of a disturbance (1209) between town and gown, and the migration of students and masters in very large numbers. Edmund ultimately resolved to devote himself to theology, was ordained priest, and took his degree in divinity. "He is the first of our archbishops," says Dean Hook, "to whose name we find the title of S.T.P. attached—the first doctor of divinity." About 1222 he was appointed treasurer of Salisbury Cathedral, and in this office, which he held about eleven years, and to which the prebend of Calne was attached, he endeared himself alike to rich and poor. In 1227 Dr Edmund was one of the preachers of the sixth crusade. In 1233 he was elected to the vacant primacy. Three elections had previously been made by the chapter, which the Pope for various reasons had refused to confirm; and this, the fourth, was made by the Pope's suggestion, as a compromise acceptable to "Pope, king, and monks," says Fuller, "three cords seldom twisted in the same cable." The pallium was sent to England without waiting for the decision of the chapter. The position of the primacy was at that time one of peculiar difficulty, and it was with unfeigned reluctance that Edmund accepted it,—feeling, says Langard, "that the timidity of his conscience would not suffer him to acquiesce in the disorders of the age, and that the gentleness of his temper did not fit him for the stern office of a reformer." The new archbishop attached himself and steadfastly adhered to the national party, whose great object was to insure the independence of the kingdom, the maintenance of the Great Charter, and the exclusion of foreigners from civil and ecclesiastical offices. Early in 1234, before his consecration, he convened a council at Westminster, by which a remonstrance was addressed to the king, requiring him, on pain of the censures of the church, to dismiss his foreign councillors, especially Peter des Roches, bishop of Winchester, through whose influence the strongholds of the kingdom were then in the hands of foreign mercenaries. The consecration of the archbishop was celebrated at Canterbury on the 2d April 1234, and the king was present with all his court. One week later the primiate held a second council, and was commissioned by it to threaten the king with excommunication if he did not comply with the terms of the former council. This measure was effectual. The archbishop was then sent into Wales to negotiate a peace with the Prince Llewelyn. In May he held a council at Gloucester, and here was accomplished a temporary reconciliation between the king and the people. In January 1236 the primiate had the costly privilege of a royal visit, Henry III. going to Canterbury to await the coming of his bride-elect, Eleanor of Provence; and on the 14th the marriage ceremony was performed by the archbishop. A few days later he officiated at the coronation of the queen. But the hopeless divergence of aims between the king and the archbishop, and the inflexible courage and decision of the latter, induced Henry to apply secretly to the Pope, Gregory IX., to send a legate to reside in England, whose authority might nullify that of the archbishop. Meanwhile, the latter issued, in 1236, his constitutions, which are of no little interest, as an expression of the strongholds they furnish of the state of the church and of general society. The picture is not a flattering one. In 1237 arrived the legate, Cardinal Otho, who at once won
his way into the royal favour. In November he held a council at St Paul's, but failed to carry his main points against the opposition of the clergy. He stood high, however, with the king, and used or abused his prerogatives for effecting his own purposes. Archbishop Edmund now found himself in opposition to both the king and the Pope; and his position was rendered still more difficult by his excommunication of Simon de Montfort and his bride Eleanor, sister of the king, whose marriage having taken a violent and perpetual widowedness he felt bound to condemn. In 1238, with a view to obtaining the support of the Pope for his project of monastic reform, Edmund went to Rome. But in this mission he failed. Not only was his purpose frustrated, but he was treated with marked insult by the Pope; and he returned to England sad at heart and burdened with pecuniary difficulties. He soon found that he was reduced to a cipher; he saw the Papal exactions continually growing—"vexed," says Fuller, "at the poll and pealing of the English people"—and saw that the legate's great object was to crush him. In 1240, therefore, he left England, and took up his abode at the abbey of Pontigny, in a town, where Thomas Becket and Stephen Langton had previously found an asylum. At his landing he was met by the queen of France, who brought her sons, among them (St) Louis, to receive his blessing. His health was now broken down, and he sighed out the remainder of his life "in quest retirement, broken only by occasional preaching. Becoming weaker and weaker, he removed, for the sake of a better climate, to the priory of Sossay, and there he died, November 16, 1240. His tomb, within a year, began to be famous for miracles, and in 1246, after much resistance on the part of the Pope, the archbishop, the staunch foe of papal extortion, was canonized. He left a work entitled Speculum Ecclesiae, which he appears to have completed at Pontigny.

Two contemporary biographies of St Edmund are extant, one by his brother Robert Rich, the other by Bertrand, prior of Pontigny, the usual edition of musculous and incredible details being found in their accounts (W L R C.).

EDMUND, or EDMUND II. (893–1016), son of Ethelred, and the last of the line of West Saxons, was, called on account of his boldness and great strength Ironside, was, on the death of Ethelred the Unready, in April 1016, proclaimed king by the citizens of London and such of the Witan as were in the city. At that time Canute the Dane was preparing an expedition against London, and he was proclaimed king by the Witan of England, which met at Southampton. In command of a magnificent fleet he anchored before London, and by cutting a ditch round that part of the city not washed by the Thames, completely surrounded it; but the citizens, fighting with great valour, repulsed all his attacks. Meanwhile Edmund was acknowledged by the West Saxons, who flockcd from every quarter to his standard; and determining to make a diversion in favour of London, he met and defeated the enemy at Ten, near Gillingham, in Dorsetshire. Canute was forced to raise the siege of London, and encountering Edmund at Seekorston, in Wilt, would have been signally defeated, had not the trustor caldeman Edric raised the head of a fallen thane which resembled that of the king, and called to the Saxons to flee, for their king was dead. Edmund, who was on the top of a hill, saved his subjects from flight by taking off his vassar and showing his countenance, but from the disorder into which they had been thrown by the untoward incident they were unable to follow up their victory. Canute retained possession of the field of battle, but the Saxons returned, and resumed the siege of London. Afterwards the Danes were defeated at Brentford on the Thames, and at Otford in Kent, and fled to the Isle of Sheppey; but being recruited, they met Edmund at Assandun (Ashdown, in Essex), where a battle was fought which virtually decided the fate of the West Saxon kings. Through a second act of treachery on the part of Edric, who fled at the decisive moment of the battle, with the portion of the army that he commanded, the Saxons were signally defeated, and their chief nobles left dead on the field. Edmund, unsanctioned by his great losses, washed still to continue the struggle, but Edric and the Witan persuaded him to be reconciled to Canute, and to consent to a division of the kingdom. Edmund retained London and all England south of the Thames, together with East Anglia and Essex, Canute taking possession of the other and larger portion. Edmund died on the 30th November of the same year, some affirm by the hand of Edric. He was buried in the great minster of Glastonbury, and on his death Canute became sole king of England.

EDMUND, or EDMUND I (Atheling), (922–946), king of the Mercians and West Saxons, was the son of Edward the Elder, and succeeded his brother Athelstan in 911, being then, it is said, only eighteen years of age, but having already gained the esteem of the people by his courage shown three years before at the battle of Brunanburh. When he succeeded his famous brother, the Northumbrians, judging the opportunity favourable, brought over Anlaf from Ireland, and set him up as their king. The Danes of the kingdom joined them, and the result of the campaign was that Edmund was compelled to make a treaty, by which he ceded a large portion of his territory to his enemy. Two years afterwards, however, on the death of Anlaf, he not only freed his kingdom, but also subdued the Britons of Cumbria or Cumberland, and bestowed their lands on Malcolm I. of Scotland, on condition of his co-operating with him in military service. On the 26th May 946 an outlaw named Leof had shipped into the banqueting-hall of Edmund, who was celebrating the festival of St Augustine at Pucklechurch in Gloucester, and the king in sudden anger, or because he suspected his designs, endeavoured to remove him, whereupon the outlaw plunged a dagger into his bosom and killed him.
various parts of his life afford subjects of controversy rather than of precise information. The place and even the country in which he was born is the first subject of dispute. A Nubian and an Egyptian origin have both been assigned to him on the basis of a doubtful reading in his work, which speaks of "the Nile of Egypt which cuts our land." In 1663 Bochart stated that he had found in a manuscript of Leo Africanus at Leyden a copy of the kids of Edrisi was born at Septa, or Cesma, on the coast of Morocco, in 493 A.D. (1099 A.D.). Caiari not only qualifies his statement, but he does not mention the authorities from which it is derived; so that its acceptance rests only upon the confidence reposed in his learning and accuracy. Edrisi was long a mighty monarch of the whole world, as far as it was known to the Islands, in the north-eastern extremity of Asia. The inconveniences of the arrangement are obvious; but the author appears to have written an illustrative treatise to accompany an actual representation of the world which he had engraved on a silver disk or possibly a silver globe.

Two valuable manuscripts of Edrisi exist in the Bibliotheque Nationale at Paris, and other two in the Bodleian Library. The first of the English MSS., which was brought over from Egypt by Creuses, is written in the Arabic character peculiar to Northern Africa. It is illustrated by a map of the known world, and by 83 other maps, containing each part of a climate, so that there are maps only for the first three climates. The second manuscript, brought by Pococke from Syria, is written in the Arabic character used in that country, and bears the date of 300 A.D., or 1500 A.D. It consists of 280 leaves, and is divided by the general and 77 particular maps, the latter consequently including all the parts of every climate. The general map was published by Dr. Vincent as "The Purposum of the Universall of Edrisi's Work in the Ecorolls was destroyed by the great fire of 1771.

The geography of Edrisi, in the original Arabic, was printed at Rome in 1692, at the Medesian press, from a manuscript preserved in the grand-ducal library at Florence. Both the paper and printing are exceedingly neat, but the volume swarms with typographical errors and forms only a clumsy epitome of the original work. The description of Mecca, which is unaccountably omitted, has been supplied by Pococke from his manuscript. In most bibliographical works this impression has been characterized as one of the rarest of books; but Adler, in a visit to Florence, found in the palace there 1129 copies, which were exposed to sale at a moderate rate. In 1619, two Oriental scholars, Gabriel Sauta and Jeanne Heronitas, published at Paris a Latin translation of Edrisi's work, bearing the title of Geographia Nubens; but it is far from accurate, particularly in the proper names. George Hieronymus Velachius, a German scholar, had prepared a copy of the Arabic original, with a Latin translation, which he purposed to have annotated with notes; but death prevented the execution of his design, and his manuscript remains deposited in the university library of Jena. See Ed. (12 Ar. Hen., n. 13) mentions that he was determined to re-edit this work, but he appears never to have executed his intention. The part relating to Africa, pre-eminent certainly in point of importance, was very ably edited in 1799 by Hartmann, who collected together all the notices relating to each particular country, and annexed the statements of the countrymen and contemporaries of Edrisi, so that his work forms nearly a complete body of Arabic geography, as far as relates to Africa. He afterwards published Hispania, 3 vol., Marburg, 1801-1818. A translation into French of the entire work, based on one of the MSS. of the Bibliotheque Nationale, was published by J. M. Dubois in 1840, and forms volumes v and vi. of the Recueil des Voyages issued by the Societé de Géographie; but a good edition of the original text is still a desideratum. A number of Oriental scholars at Leyden determined in 1861 to undertake the task: Spain and Western Europe were assigned to Professor Dory; Eastern Europe and Western Asia to Doctor Engelmann; Central and Eastern Asia to Dr. and Mrs. Goodyear; and Africa to Professor Goodyear. The first portion of the work appeared in 1866, under the title of Descriptions de l'Afrique et de l'Asie par Edrisi, texte arabe publi par R. Dory et M. J. de Goody, but the other collaborators have hitherto found impossible to furnish their quota.

EDUCATION. This article is mainly concerned with Ongas of the history of educational theories in the chief countries of Education, and their development. It has not been the object of the writer to give a history of the practical working of these theories, and still less to sketch the outlines of the science of teaching, which may be more conveniently dealt with under another head. The earliest education is that of the family. The child must be trained to acquire with its parents' convenience, and to acquire those little arts which will help in maintaining the economy of the household. It was long before any attempt was made to improve generations as they succeeded each other. The earliest schools were those of the priests. As soon as an educated priesthood had taken the place of the diviners and jugglers who abused the credulity of the earliest races, schools of the prophets became a necessity. The training required for ceremonials, the common life apart from the family, the accomplishments of reading and singing, afforded a nucleus for the organization of culture and an opportunity for the training of the scribe or scholar in advance of his age. Convenience and gratitude confirmed the monopoly of the clergy. The schools of Judea and Egypt were ecclesiastical. The Jews had but little effect on the progress of science, but our obligations to the priests of the Nile valley are great indeed. Much of their learning is obscure and the reason to conclude that there is no branch of science in which they did not progress at least so far as observation and careful registration of facts could carry them. They
were a source of enlightenment to surrounding nations. Not only the great lawyer of the Jews, but those who were most active in stimulating the nascent energies of Hellenism were careful to train themselves in the wisdom of the Egyptians. Greece, in giving an undying name to the literature of Alexandria, was only repaying the debt which she had incurred centuries before. Education became secular in countries where the priesthood did not exist as a separate body. At Rome, until Greece took her conqueror captive, a child was trained for the duties of life in the forum and the senate house. The Greeks were the first to develop a science of education distinct from ecclesiastical training. They divided their subjects of study into music and gymnastics, the one comprising all mental, the other all physical training. Music was at first little more than the study of the art of expression. But the range of intellectual education which had been developed by distinguished musical teachers was further widened by the Sophists, until it received a new stimulus and direction from the work of Socrates. Who can forget the picture left us by Plato of the Athenian palestra, in which Socrates was sure to find his most ready listeners and his most ardent disciples? In the intervals of running, wrestling, or the bath, the young Pheidrus or Thetastus discoursed with the philosophers who had come to watch them on the good, the beautiful, and the true. The lowest efforts of their teachers were to fit them to maintain any view they might adopt with acuteness, elegance, readiness, and good taste. Their highest efforts were to stimulate a craving for the knowledge of the unknowable, to rouse a dissatisfaction with received opinions, and to excite a curiosity which grew stronger with the revelation of each successive mystery. Plato is the author of the first systematic treatise on education. He deals with the subject in his earlier dialogues, he enters into it with great fulness of detail in the Republic, and it occupies an important position in the Laws. The views thus expressed differ considerably in particular, and it is therefore difficult to give concisely the precepts drawn up by him for our obedience. But the same spirit underlies his whole teaching. He never forgets that the beautiful is indistinguishable from the true, and that the mind is best fitted to solve difficult problems which has been trained by the enthusiastic contemplation of art. Plato proposes to inculcate education to the state. He lays great stress on the influence of race and blood. Strong and worthy children are likely to spring from strong and worthy parents. Music and gymnastics are to develop the emotions of young men during their earliest years,—the one to strengthen their character for the contest of life, the other to excite in them varying feelings of resentment or tenderness. Reverence, the ornament of youth, is to be called forth by well-chosen fictions; a long and rigid training in science is to precede discussion on more important subjects. At length the goal is reached, and the ripest wisdom is ready to be applied to the most important practice.

The great work of Quintilian, although mainly a treatise on oratory, also contains incidentally a complete sketch of a theoretical education. His object is to show us how to form the man of practice. But what a high conception of practice is his! He wrote for a race of rulers. He inculcates much which has been attributed to the wisdom of a later age. He urges the importance of studying individual dispositions, and of tenderness in discipline and punishment. The Romans understood no systematic training except in oratory. In their eyes every citizen was a born commander, and they knew of no science of government and political economy. Cicero speaks slightly even of jurisprudence. Any one, he says, can make himself a jurist in a week, but an orator is the production of a lifetime. No statement can be less true than that a perfect orator is a perfect man. But wisdom and philanthropy broke even through that barrier, and the training which Quintilian expounds to us as intended only for the public speaker, would, in the language of Milton, fit a man to perform justly, wisely, and magnanimously all the offices, both public and private, of peace and war.

Such are the ideas which the old world has left us. On one side man beautiful, active, clever, receptive, emotional, quick to feel, to show his feeling to argue, to refine, greedy of the pleasures of the world, perhaps a little neglectful of its duties, learning restrained as an unjust stinting of the bounty of nature, inquiring eagerly into every secret, strongly attached to the things of this life, but elevated by an unabated striving after the highest ideal, setting no value but upon faultless abstractions, and seeing reality only in heaven, on earth mere shadows, phantoms, and copies of the unseen. On the other side man practical, energetic, eloquent, tinged but not imbued with philosophy, trained to spare neither others, reading and thinking only with an apology, best engaged in defending a political principle, in maintaining with gravity and solemnity the conservation of ancient freedom, in leading armies through unexplored deserts, establishing roads, fortresses, settlements, the results of conquest, or in ordering and superintending the slow, certain, and utter annihilation of some enemy of Rome. Has the modern world ever surpassed their type? Can we in the present day produce anything by education except by combining, blending, and modifying the self-culture of the Greek or the self-sacrifice of the Roman?

The literary education of the earliest generation of Christians was obtained in the pagan schools, in those great academies which existed even down to the 5th century, which flourished in Europe, Asia, and Africa, and attained perhaps their highest development and efficiency in Gaul. The first attempt to provide a special education for Christians was made at Alexandria, and is illustrated by the names of Clement and Origen. The later Latin fathers took a bolder stand, and rejected the suspicious aid of heathenism. Tertullian, Cyprian, and Jerome washed the antagonism between Christianity and Paganism to be recognized from the earliest years, and even Augustine condemned with harshness the culture to which he owed so much of his influence, the worship of the Gnostics of the Middle Ages. It was either that of the monastery or the church. The Judent was a spot, and the teaching which they proscribed. Long hours were spent in the duties of the church, and in learning to take a part in elaborate and useless ceremonies. A most important part of the monastery was the writing room, where mssals, psalters, and breviaries were copied and illuminated, and too often a masterpiece of classic literature was effaced to make room for a treatise of one of the fathers or the sermon of an abbot. The discipline was hard, the rod ruled all with indiscernible and impartial severity. How many generations have had to suffer for the flagellants of those times! Hatred of learning, antagonism between the teacher and the taught, the belief that no training can be effectual which is not repulsive and distasteful, that no subject is proper for instruction which is acquired with ease and pleasure,—these ideals of false education have their root and origin in monkish cruelty. The joy of human life would have been in danger of being stamped out if it had not been for the warmth and colour of a young knight's boyhood. He was equally well
broken in to obedience and hardship, but the obedience was the
willing service of a mistress whom he loved, and the hardship
the permission to share the danger of a leader whom he
emulated. The seven arts or manner of monastic training were Grammar,
Dialectics, Rhetoric, Music, Arithmetic, Geometry, Astronomy,
which together formed the trivium and quadrivium, the seven
years' course, the divisions of which have profoundly affected our modern training.

The schools of Charles the Great have lately been investi-
gated as one of these liberal arts. Cassiodorus, who wrote De Operibus
Disciplinis about 500, was also largely used as a text book in the schools. Astronomy
was taught by the Cisto-Janus, a collection of doggerel
hexameters like the Propria gus maribus, which contained the chief
festivals in each month, with a memoria technica for recollecting when they occurred. The seven
knights accomplishments, as historians tell us, were to ride, to
swim, to shoot with the bow, to box, to hawk, to play
chess, and to make verses. The verses thus made were
not in Latin, but sonnets of Ovid or Horace, whose
pagan beauties were wrested into the service of religion, but
sonnets, ballads, and canzonets in soft
Provençal or melodious Italian. In nothing, perhaps, is the
difference between these two forms of education more clearly shown
than in their relations to women. A young monk was
brought up to regard a woman as the worst among the
many temptations of St Antony. His life knew no
domestic tenderness or affection. He was surrounded and
cared for by celibates, to be himself a celibate. A page
was trained to receive his best reward and worst punishment
from the smile or frown of the lady of the castle, and as
he grew to manhood to cherish an absorbing passion as
the strongest stimulus to a noble life, and the contempla-
tion of female virtue, as embodied in an Isolde or a Beatrice,
as the truest earnest of future immortality.

Both these forms of education disappeared before the
Renaissance and the Reformation. But we must not suppose that no efforts were made to improve upon the
narrowness of the schoolmen or the idleness of chivalry.
The system of Charles the Great have lately been investi-
gated by Mr Mullinger, but we do not find that they
materially advanced the science of education. Vincent
of Beauvais has left us a very complete treatise on
teaching, written about the year 1245. He was the
friend and counsellor of St Louis, and we may discern his influence in the instructions which were left by that saintful
king for the guidance of his son and daughter through life.
The end of this period was marked by the rise of
universities. Bologna devoted itself to law, and numbered
12,000 students at the end of the 12th century. Salerno
adopted as its special province the study of medicine, and
Paris was thronged with students from all parts of Europe,
who were anxious to devote themselves to a theology which
passed by indefinite gradations into philosophy. The
14th and 15th centuries witnessed the rise of universities and
academies in almost every portion of Europe. Perhaps the
most interesting among these precursors of a higher culture
were the Brethren of the Common Life, who were domiciled in
the rich meadows of the Yssel, in the Northern Nether-
lands. The metropolis of their organization was Deventer,
the best known name among them that of Gerhard Groote.
They devoted themselves with all humility and self-sacrifice
to the education of children. Their schools were crowded.
Boys-and-number 1200 pupils, Zwolle 1600. For a
hundred years no part of Europe shone with a brighter
lustre. As the divine comedy of Dante represents for us
the learning and piety of the Middle Ages in Italy, so the
Imitation of Thomas à Kempis keeps alive for us the
memory of the purity and sweetness of the Dutch
community. But they had not sufficient strength to preserve
their supremacy among the necessary developments of the
age. They could not support the glare of the new Italian
learning; they obtained, and it may be feared deserved, the
title of obscurantists. The Epitome Obscurorum Vrorum,
the wittiest squib of the Middle Ages, which Luther and Melanchthon
was the true and so subtle in its satire that it was hailed as a blow struck
in defence of the ancient learning, consists in great part of the
lamentations of the brethren of Deventer over the new age,
which they could not either comprehend or withstand.

The education of the Renaissance is best represented by the
name of Erasmus, that of the Reformation by the names of
Luther and Melanchthon. We have no space to give an
account of that marvellous resurrection of the mind and
spirit of Europe when touched by the dead hand of an
extinct civilization. The history of the revival of letters
belongs rather to the general history of literature than to
that of education. But there are two names whom we
ought not to pass over. Vittorino da Feltre was summoned
by the Gonzagas to Mantua in 1424; he was lodged in a
spacious palace, with galleries, halls, and colonnades
decorated with frescoes of playing children. In person he
was small, quick, and lively—a born schoolmaster, whose
whole time was spent in devotion to his pupils. We are told
of the children of his patron, how Prince Gonzaga recited
200 verses of his own composition at the age of fourteen,
and how Princess Cecilia wrote elegant Greek at the age of
ten. Vittorino died in 1477. He seems to have reached
the highest point of excellence as a practical schoolmaster
whom the Italian Renaissance, on the other hand, had
left us in his Cortigiano the sketch of a cultivated
nobleman in those most cultivated days. He shows by
what precepts and practice the golden youths of Verona
and Venice were formed, who live for us in the plays of
Shakespeare as models of knightly excellence. For our
instruction, it is better to have recourse to the pages of
Erasmus. He has written the most minute account of his
method of teaching. The child is to be formed into a good
Greek and Latin scholar and a pious man. He fully
grasps the truth that improvement must be natural and
gradual. Letters are to be taught playing. The rules of
grammar are to be few and short. Every means of arousing
interest in the work is to be fully employed. Erasmus is
no Ciceronian. Latin is to be taught so as to be of
use—a living language adapted to modern wants. Children
should learn an art—painting, sculpture, or architecture.
Idleness is above all things to be a bud. The education
of girls is as necessary and important as that of boys.
Much depends upon home influence; obedience must be
strict, but not too severe. We must take account of
individual peculiabilities, and not force children into
clusters against their will. We shall obtain the best result
by following nature. It is easy to see what a contrast this
scheme presented to the monkish training,—to the routine
of useless technicalities enforced amidst the shouts of
teachers and the lamentations of the taught.

Still this culture was but for the few. Luther brought
Reformation to the schoolmaster into the cottage, and laid the foundations
of the system which is the chief honour and strength of
modern Germany, a system by which the child of the
humblest peasant, by slow but certain gradations, receives
the best education which the country can afford. The
precepts of Luther found their way into the hearts of his
countrymen in short, pithy sentences, like the sayings of
poor Richard. The purification of thought and action went hand in hand with the purification of religion,
and these claims to affection are indisputably united in the
minds of his countrymen. Melanchthon, from his editions
school books and his practical labours in education, earned him the title of Inspector Germanicus. Aristotle had been succeeded from his predecessors in the schools, and the laudation of his importance of Greek, the terror of the obscurantists, is the author of a Greek grammar. He wrote elementary text books on each department of the trivium—grammar, rhetoric, and logic. He wrote Introductory Lessons on physical science. He lectured at the university of Vittenberg, and for ten years, from 1519 to 1529, kept school privately in his own house. Horace was his private pupil. His pupils were taught to learn the love of his heart, ten lines at a time. The tender and lines of his well-known portraits show clearly the master of the painful, accurate scholar, and contrast with the bare power of the genial Luther. He in 1560, lacked for the church which he has to found. The difference to carry Protestantism the house of the peasant, he at least made it acceptable to the health of the peasant, he at least made it acceptable to the present day all over Europe, and was known how to combine and to trace the whole course of his influence, but he is in all probability as much answerable as any one for the great emphatic reformation which has worked in the 16th century, and which went far to ruin and corrupt its literature. Nowhere perhaps had he more effect than in England. Our older public schools, on breaking with the ancient faith, looked to Sturm as their model of Protestant education. His name and example became familiar to us by the exertions of his friend Ascham Westminster, under the long reign of Busby, received a form which was generally accepted as the type of a gentleman's education.

The Public School Commission of 1862 found that the plan had been used by the great citizens of Strasburg, and copied by his admirers, had remained unchanged until within the memory of the present generation. Wolfgang Ratke or Ratze. Ratzeus was born in Holstein in 1571. He anticipated some of the best improvements in the method of teaching which have been made in modern times. He was like many of those who have tried to improve existing methods in advance of his age, and he was rewarded for his labours at Augsburg, Weimar, and Kothen by persecution and imprisonment. Can we wonder that education has improved so slowly when so much pain has been taken to silence and extinguish those who have devoted themselves to its improvement? His chief rules are: 1. Begin everything with prayer. 2. Do everything in order, following the course of nature 3. One thing at a time. 4. Often repeat the same thing. 5. Teach everything first in the mother tongue. 6. Proceed from the mother tongue to other languages. 7. Teach without compulsion. Do not beat children to make them learn. Pupils must love their masters, not hate them. Nothing should be learnt by heart. Sufficient time should be given to play and recreation. Learn one thing before going on to another. Do not teach for two hours consecutively. 8. Uniformity in teaching, also in school books, especially grammars, which may with advantage be made comparative. 9. Teach a thing first, and then the reason of it. Give no rules before you have given the examples. Teach no language out of the grammar, but out of authors. 10. Let everything be taught by induction and experiment. Most of these precepts are accepted by all good teachers in every country, all of them are full of wisdom. Unfortunately their author saw the faults of the teaching of his time more clearly than the means to remove them, and he was more successful in forming precepts than in carrying them out. Notwithstanding these drawbacks, he deserves a honourable place among the forerunners of a rational education.

John Amos Comenius was the antithesis to Sturm, and Constance a greater man than Ratze. Born a Moravian, he passed a wandering life, among the troubles of the Thirty Years' War in poverty and obscurity. But his ideas were accepted by the most advanced thinkers of the age, notably in many respects by our own Milton, and by Ossenborn the chancellor of Sweden. His school books were spread throughout Europe, The Janua Litterarum Renovata was translated into twelve European and several Asiatic languages. His works, especially the Didascalica magna, an encyclopaedia of the science of education, are constantly reprinted at the present day, and the system which he sketched will be found to forecast the education of the future. He was repelled and disgusted by the long delays and pedantry of the schools. His highest mind conceived that if teachers would but follow nature instead of forcing it against its bent, take full advantage of the innate desire for activity and growth, all men might be able to learn all things. Languages should be taught as the mother tongue is taught, by conversations on ordinary topics, pictures, object lessons, should be freely used; teaching should go hand in hand with a cheerful, elegant, and happy life. Comenius included in his course...
the teaching of the mother tongue, singing, economy, and politics, the history of the world, physical geography, and a knowledge of arts and handicrafts. But the principles on which he most insisted, which forms the special point of his teaching, and in which he is followed by Milton, is that the teaching of words and things must go together hand in hand. When we consider how much time is spent over new languages, what waste of energy is lavished on mere preparation, how it takes so long to lay a foundation that there is no time to rear a building upon it, we must conclude that it is in the acceptance and development of this principle that the improvement of education will in the future consist. Any one who attempts to isolate this great lesson will find that its first principles are contained in the writings of Comenius. But this is not the whole of his claim upon our gratitude. He was one of the first advocates of the teaching of science in schools. His kindness, gentleness, and sympathy make him the forerunner of Pestalozzi. His general principles of education would not sound strange in the treatise of Herbert Spencer.

The Protestant schools were now the best in Europe, and the monkish institutions were left to decay. Catholics would have remained behind in the race if it had not been for the Jesuits. Ignatius Loyola gave this direction to the order which he founded, and the programme of studies, which dates from the end of the 16th century, is in use, with certain modifications, in English Jesuit schools at the present day. In 1550 the first Jesuit school was opened in Germany, in 1700 the order possessed 612 colleges, 157 normal schools, 59 novitiates, 340 residences, 200 missions, 28 professorial homes, and 24 universities. The college of Clermont had 3000 students in 1695. Every Jesuit college was divided into two parts, the one for higher the other for lower education,—the studia superiores, and the studia inferiores. The studia superiores, answering to the modern gymnasiaum, was divided into two sections. The principles were teaching grammar (rudiments), grammar (accidence), and syntax, the last two humanity and rhetoric. The motto of the school was leges, scriba, locuplet. —you must learn not only to read and write a dead language, but to talk. Pursian was even more exaggerated than by Sturm. No word might be used which did not rest upon a special authority. The composition of Latin verses was strongly encouraged, because they were a convenient sacrifice. Whatever may have been the service of the Jesuits in past times, we have little to hope for them in the improvement of education at present. Governments have, on the whole, acted wisely by checking and suppressing their colleges. The ratio studiorum is antiquated and difficult to reform. In 1531 it was brought more into accordance with modern ideas by Roothaan, the general of the order. Becker has made a more powerful attack on anything, pursued a policy oflegation. The Italian Government, in taking possession of Rome, found that the pupils of the Collegio Romano were far below the level of modern requirements.

It may be imagined that, by this organization both Catholics and Protestants were apt to degenerate into pedantry, both in name and purpose. The schoolmaster had a great deal too much the best of it. The Latin school was tabulated and organized until every half hour of a boy's time was occupied; the Jesuit school took possession of the pupil body and soul. It was, therefore, to be expected that a stand should be made for common sense in the direction of practice rather than theory, of wisdom instead of learning. Montaigne has left us the most delightful utterances about education. He says that the faults of the education of his day consist in over-estimating the intellect and rejecting morality, in exaggerating memory and deprecating useful knowledge. He recommends a tutor who should draw out the pupil's own power and originality, to teach how to live well and to die well, to enforce a lesson by practice, to put the mother tongue before foreign tongues, to teach all many exercises, to educate the perfect man. Away with force and compulsion, with severity and the rod. John Locke, more than a Locke, hundred years afterwards, made a more powerful and 1692.-systematic attack on useless knowledge. His theory of 1704. the origin of ideas led him to assign great importance to education, while his knowledge of the operations of the human mind lends a special value to his advice. His treatise has received in England more attention than it deserves, partly because we have so few books written upon the subject on which he treatises. Part of which he treatises is used at the present day; part it would be well to follow, or at any rate to consider seriously, especially he condemn-
tion of repetition by heart as a means of strengthening the memory, and of Latin verses and themes. He sets before himself the production of the man, a sound mind in a sound body. His knowledge of medicine gives great value to his advice on the earliest education, although he probably exaggerates the benefits of enforced hardships. He recommends home education without harshness or severity of discipline. Emulation is to be the chief spring of action, knowledge is far less valuable than a well-trained mind. He prizes that knowledge most which fits a man for the duties of the world, speaking languages, accounts, history, law, logic, rhetoric, natural philosophy. He inculcates the importance of drawing, dancing, riding, fencing, and trades. The part of his advice which made most impression upon his contemporaries was the teaching of reading and arithmetic by well-considered games, the discouragement of an undue absorption of language, as that of the treatise of Locke, and probably refers to later time, in the better days of French education. The success of the Jansenists was too much for the jealousy of the Jesuits. Neither poetry, nor wit, nor virtue could save them. A light was quenched which would have given an entirely different direction to the education of France and of Europe. No one can visit without emotion that retired nook which lies hidden among the forests of Versalles, where the old brick dove-cot, the pillars of the church, the trees of the desert alone remain to speak to us of Pascal, Racine, and the Mère Angélique. The principles of Port Royal found some supporters in a later time, in the better days of French education before monarchy and militarism had crushed the life out of the nation. Rollin is never mentioned without the epithet bon, a testimony to his wisdom, virtue, and simplicity. Feuillon may be reckoned as belonging to the same school, but he was more fitted to mix and grapple with mankind.

Far more important in the literature of this subject than the treatise of Locke is the Tractate of Education by Milton, "the few observations," as he tells us, "which flowered off, and are, as it were, the burnishings of many hours of repetition." This essay is addressed to Samuel Hartlib, a great friend of Comenius, and probably refers to a project of establishing a university in London. "I will point you out," Milton says, "the right path of a virtuous and noble education,—labours, indeed, at first ascent, but else so smooth and green and full of godly prospects and melodious sounds on every side, that the harp of Orpheus is not more charming. This is to be done between twelve and one-and-twenty, in an academy containing about a hundred and thirty scholars, which shall be at once school and university,—not needing a remove to any other house of scholarship except it be some peculiar college of law and physics, where they mean to be practitioners." The important truth enunciated is quite in the spirit of Comenius that the learning of things and words is to go hand in hand. The curriculum is very large. Latin, Greek, arithmetic, geometry, agriculture, geography, physiology, physics, trigonometry, fortification, architecture, engineer, navigation, anatomy, medicine, poetry, Italian, law both Roman and English, Hebrew with Chaldee and Syrian, history, oratory, poetry. But the scholars are not to be trained for war, both on foot and on horseback, to be practised "in all the locks and grapes of wrestling," they are to "recreate and compose their travailing spirits with the divine harmonies of music heard or learnt." "In those venerable seasons of the year when the air is calm and pleasant, they were an injurious and a sullenness against nature not to go out and see her riches, and partake in her rejoicing with heaven and earth. I should not then be a persuader to them of studying much then, after two or three years that they have well laid their grounds, but to ride out in companies with prudent and steady guides to all the quarters of the land." The whole treatise is full of wisdom, and deserves to be studied again and again. Vain glory as it may appear to some at first sight, if translated into the language of our own day, it will be found to abound with sound practical advice. Only," Milton says in conclusion, "I believe that this is not a book for the cursory man to shoot who counts himself a teacher, but will require sinews almost equal to those which Homer gave Ulysses; yet I am persuaded that it may prove much more easy in the essay than it now seems at a distance, and much more instructive if God have so decreed and the age have spirit and capacity enough to apprehend." Almost while Milton was writing this treatise, he might have seen an attempt to realize something of his ideal in Port Royal. What a charm does this name awaken! Yet how few of us have made a pilgrimage to that secluded valley! Here we find the first time in the modern world, the highest gifts of the greatest men of a country applied to the business of education. Arnauld, Lancelot, Nicole did not commence by being educational philosophers. They began with a small school, and developed their method as they proceeded. Their success has seldom been surpassed. But a more lasting memorial than their pupils are the books which they sent out, which bear the name of their cloister. The Port Royal Logic, General Grammar, Greek, Latin, Italian, and Spanish Grammars, the Garden of Greek Flowers which taught Greek to Gibbon, the Port Royal Geometry, and their translations of the classics held the first place among school books for more than a century. The success of the Jansenists was too much for the jealousy of the Jesuits. Neither poetry, nor wit, nor virtue could save them. A light was quenched which would have given an entirely different direction to the education of France and of Europe. No one can visit without emotion that retired nook which lies hidden among the forests of Versalles, where the old brick dove-cot, the pillars of the church, the trees of the desert alone remain to speak to us of Pascal, Racine, and the Mère Angélique. The principles of Port Royal found some supporters in a later time, in the better days of French education before monarchy and militarism had crushed the life out of the nation. Rollin is never mentioned without the epithet bon, a testimony to his wisdom, virtue, and simplicity. Feuillon may be reckoned as belonging to the same school, but he was more fitted to mix and grapple with mankind.

No history of education would be complete without the name of August Hermann Francke, the founder of the school of Pietists, and of a number of institutions which now form almost a suburb in the town of Halle to which his labours were devoted. The first scenes of his activity were Leipzig and Dresden; but in 1629, at the age of 29, he was made pastor of Glucka near Halle, and professor in the newly established university. Three years later he commenced his poor school with a capital of seven guineas which he found in the poor box of his house. At his death in 1727 he left behind him the following institutions—a pedagogium, or training college, with 82 scholars and 70 teachers receiving education, and attendants, the Latin school of the orphan asylum, with 3 inspectors, 32 teachers, 490 scholars, and 10 servants; the German town schools, with 4 inspectors, 98 teachers, 3 female teachers, and 1725 boys and girls. The establishment for orphan children contained 109 boys, 34 girls, and 10 attendants. A cheap public dining table was attended by 255 students and 360 poor scholars, and besides this there was an apothecary's and a bookseller's shop. Francke's principles of education were strictly religious. Hebrew was included in his curriculum, but the heathen classics were treated with slight respect. The Homilies of Macarius were read in the place of Thucydes. As might be expected, the rules laid down for discipline and moral training breathed a spirit of deep affection and sympathy. Francke's great merit, however, is to have left us a model of institutions by which children of all ranks may receive an education to fit them for any position in life. The Franckesche Stiftungen are still, next to the university, the centre of the intellectual life of Halle, and the different schools which they contain give instruction to 3500 children.

We now come to the book which has had more influence than any other on the education of later times. The "Emile" of Rousseau was published in 1762. It produced an
astonishing effect throughout Europe. Those were days when the cultivated world vibrated to any touch of new philosophy. French had spread the general medium of thought. French learning stood in the same relation to the rest of Europe as German learning does now; and any discovery of D'Alembert, Rousseau, or Maupertuis travelled with inconceivable speed from Vermissis to Schleswig, from the Spree to the Rhine. Kant's distant home of Königsberg broke for one day through his habits, more regular than the town clock, and stayed at home to study the new revelation. The burthen of Rousseau's message was nature, such a nature as never did and never will exist, but still a name for an ideal worthy of our struggles. He revolted against the false civilization which he saw around him; he was penetrated with sorrow at the shams of government and society, at the misery of the poor existing side by side with the heartlessness of the rich. The child should be the pupil of nature. He lays great stress on the earnest education. The chief year of life is in every respect the most important. Nature must be closely followed. The child's tears are petitions which should be granted. The naughtiness of children comes from weakness; make the child strong and he will be good. Children's destructiveness is a form of activity. Do not be too anxious to make children talk; he satisfied with a small vocabulary. Lay aside all peddled caps and baby jumpers. Let children learn to walk by learning that it hurts them to fall. Do not insist too much on the duty of obedience as on the necessity of submission to natural laws. Do not argue too much with children; educate the heart to wish for right actions, before all things study nature. The chief moral principle is that for Emile is to be taught by the real things of life, by observation and experience. At twelve years old he is scarcely to know what a book is; to be able to read and write at fifteen is quite enough. We must first make him a man, and that chieflly by athletic exercises. Education should be to measure, count, and weigh accurately; teach him to draw; tune his ear to time and harmony; give him simple food, but let him eat as much as he likes. Thus at twelve years old Emile is a real child of nature. His carriage and bearing are fair and confident, his nature open and candid, his speech simple and to the point; his ideas are few but clear; he knows nothing by learning, much by experience. He has read deeply in the book of nature. His mind is not on his tongue but in his head. He speaks only one language, but knows what he is saying, and can do what he cannot describe. Routine and custom are unknown to him; authority and example affect him not; he does what he thinks right. He understands nothing of duty and obedience, but he will do what you ask him, and will expect a similar service of you in return. His strength and body are fully developed; he is first-rate at running, jumping, and judging distances. Should he die at this age he will so far have lived his life. From twelve to fifteen Emile's practical education is to continue. He is still to avoid books which teach not learning itself but to appear learned. He is to be taught and to practice some handicraft. Half the value of education is to waste time wisely, to tide over dangerous years with safety, until the character is better able to stand temptation. At fifteen a new era commences. The passions are awakened; the care of the teacher should now redouble; he should never leave the helm. Emile having gradually acquired the love of himself and of those immediately about him, will begin to love his kind. Now is the time to teach him history, and the mechanism of society, the world it is, and as it might be. Still an encumbrance of useless and burdensome knowledge is to be avoided. Between this age and manhood Emile learns all that it is necessary for him to know. It is, per-
E D U C A T I O N

The doctrines of the philanthropists; the limits of learning were enlarged; study became a pleasure instead of a pain, scope was given for healthy exercise, the school became light, airy, and cheerful. A charge of superficiality and weakness was brought against this method of instruction, but the gratitude which our generation of teachers owes to the unabated love and faith of these devoted men cannot be denied or refused. The end of the 18th century saw a great development given to classical studies. The names of Cellarius, George, Ernesti, and Heyne are perhaps more celebrated as scholars than schoolmasters. To them we owe the great importance attached to the study of the classics, both on the Continent and in England. They brought into the schools the philology which F. A. Wolf had organized for the universities. Pestalozzi, on the other hand, was completely and entirely devoted to education. His greatest merit is that he set an example of absolute self-abnegation, that he lived with his pupils, played, starved, and suffered with them, and clung to their minds and hearts with an affectionate sympathy which revealed to him every minute difference of character and disposition. Pestalozzi was born at Zurich in 1746. His father died when he was young, and his mother, who was of no good condition, brought him up by her motherly labours. His earliest years were spent in schemes for improving the condition of the people. The death of his friend Bluntschli turned him from political schemes, and induced him to devote himself to education. He married at 23, and bought a piece of waste land in Aargau, where he attempted the cultivation of madder. Pestalozzi knew nothing of business, and the plan failed. Before then he had opened his farm-house as a school, but in 1780 he had to give this up also. His first book published at this time was The Evening Hours of a Hermits, a series of aphorisms and reflections. This was followed by his masterpiece, Leonard and Gertrude, an account of the gradual reformation, first of a household, and then of a whole village, by the efforts of a good and devoted woman. It was read with avidity in Germany, and the name of Pestalozzi was rescued from obscurity. His attempts to follow up this literary success were failures. The French invasion of Switzerland in 1798 brought into relief his truly heroic character. A number of children were left in Canton Unterwalden on the shores of the Lake of Lucerne, without parents, home, food, or shelter. Pestalozzi collected a number of them into a deserted convent, and spent his energies in reclaiming them. "I was," he says, "from morning till evening, almost alone in their midst. Everything which was done for their body or soul proceeded from my hand. Every assistance, every help in time of need, every teaching which they received, came immediately from me. My hand lay in their hand, my eye rested on their eye, my tears flowed with theirs, and my laughter accompanied theirs. They were out of the world, they were out of Stanz; they were with me, and I was with them. Their soup was mine, their drink was mine. I had nothing, I had no housekeeping, no friend, no servants around me; I had them alone. Were they well I stood in their midst; were they ill, I was at their side. I slept in the middle of them. I was the last who went to bed at night, the first who rose in the morning. Even in bed I prayed and taught with them until they were asleep—the time I wished it to be so." Thus he passed the winter, but in June 1799 the building was required by the French for a hospital, and the children were dispersed. We have dwelt especially on this episode of Pestalozzi's life, because in this devotion lay his strength. In 1801 he gave an exposition of his theories on education in the book How Gertrude teaches her Children. His method is to proceed from the easier to the more difficult. To begin with observation, to pass from observation to consciousness, from consciousness to speech. Then come measuring, drawing, writing, numbers, and so reckonings. In 1839 he had been enabled to establish a school at Burgdorf, where he remained till 1854. In 1802, he went as deputy to Paris, and did his best to interest Napoleon in a scheme of national education, but the great conqueror said that he could not trouble himself about the alphabet. In 1805 he removed to Yverdon on the Lake of Neufchatel, and for two years worked steadily at his task. He was visited by all who took interest in education,—Talleyrand, Cape d'Istria, and Madame de Stael. He was praised by Wilhelm von Humboldt and by Fichte. His pupils included Ramsauer, Delbruck, Blochmann, Carl Ritter, Froebel, and Zeller. About 1815 discussions broke out among the teachers of the school, and Pestalozzi's last ten years were chequered by weariness and sorrow. In 1825 he retired to Neufib, the home of his youth, and after writing the adventures of his life, and his last work, the Swiss Song, he died in 1827. As he said himself, the real work of his life did not lie in Burgdorf or in Yverdon, the products rather of his weakness than of his strength. It lay in the principles of education which he practised, the development of his observation, the training of the whole man, the sympathetic application of the teacher to the taught, of which he was an example in his six months' labours at Stanz. He shewed what truth there was in the principles of Comenius and Rousseau, in the union of training with information, and the submissive following of nature, he has had the deepest effect on all branches of education since his time, and his influence is far from being exhausted.

The Emile of Rousseau was the point of departure for an awakened interest in educational theories which has continued unto the present day.

Few thinkers of eminence during the last hundred years have failed to offer their contributions more or less directly on this subject. Poets like Richter, Herder, and Goethe, philosophers such as Kant, Fichte, Hegel, Schlegel, Schopenhauer, psychologists such as Herbart and Beneke, have left directions for our guidance. Indeed, during this time the sciences of education or pedagogy, as the Germans call it, Pedagogik may have been said to have come into existence. It has gone from the sphere of artificial science to a definite study of the nature of man, of man's powers and their development, and of the means of training the mind of the infant. It has gone from the abstracted but little attention in England, but it is an important subject of study at all German universities, and we may hope that the example given by the establishment of chairs of education in the Scotch universities may soon be followed by the other great centres of instruction in Great Britain. Jean Paul called his book Leben, after Richter, the Roman goddess to whom the father dedicated his new-born child, in token that he intended to rear it to manhood. He lays great stress on the preservation of individuality of character. He believes that man would be so far as possible a free agent, a free being, if he were a free agent. He has the children taught in an nursery, free to run about, free to make the best of themselves, free to develop their own character, free to form their own character, free to gain their freedom. But this is the history of the future, the history of the future. The most characteristic passage is that which describes the father's return to the country of education after a year's absence. As he is riding alone, wondering in what guise he will meet his son, a multitude of horses rush by at full gallop, "The monstrous hairy-whirls past the wanderer, a fair boy among the keepers looks at him with surprise, pulls in, leaps down, and embraces his father." He then learns that an agricultural life had not suited his son, that the superiors had discovered that he was fond of animals, and had set the young peasant to the occupation of which nature had destined him. The system of Jacotot has aroused great interest in this Jacotot country. His author was born at Dijon in 1770. In 1815 he retired to Louvain and became professor there, and director of the Belgian military school. He died in 1840. His method of teaching is based on three principles:

Pestalozzi, 1746-1827.
1. All men have an equal intelligence.
2. Every man has received from God the faculty of being able to instruct himself.
3. Every thing is in every thing.

The first of these principles is certainly wrong, although Jacotot tried to explain it by asserting that, although men had the same intelligence, they differed widely in the will to make use of it. Still it is important to assert that nearly all men are capable of receiving some intellectual education, provided the studies to which they are directed are wide enough to engage their faculties, and the means taken to interest them are sufficiently ingenious. The second principle lays down that it is more necessary to stimulate the pupil to learn for himself, than to teach him didactically. The third principle explains the process which Jacotot adopted. To one learning a language for the first time he would give a short passage of a few lines, and encourage the pupil to study the first words, then the letters, then the grammar, then the full meaning of the expressions, until by iteration and accretion a single paragraph took the place of an entire literature. Much may be effected by this method in the hands of a skilful teacher, but a charlatan might make it an excuse for ignorance and neglect.

Among those who have improved the methods of teaching, we must mention Bell and Lancaster, the joint-discoverers of the method of mutual instruction, which, if it has not effected everything which its founders expected of it, has produced the system of pupil-teachers which is now common in our schools. Froebel also deserves an honourable place as the founder of the Kindergarten, a means of teaching young children by playing and amusement. His plan has a far wider significance than this limited development of them, is likely to be fruitful of results to future workers.

The last English writers on education are Mr Herbert Spencer and Mr Alexander Bain, the study of whose writings will lead us in those regions of pedagogics which have been most recently explored. We need not follow Mr Spencer into his defence of science as the worthiest object of study, or in his rules for moral and physical training, except to say that they are sound and practical. In writing of intellectual education, he insists that we shall attain the best results by closely studying the development of the mind, and availing ourselves of that amount of force which nature puts at our disposal. The mind of every being is naturally active and vigorous, indeed it is never at rest. But for its healthy growth it must have something to work upon, and, therefore, the teacher must watch its movements with the most sympathetic care, in order to supply exactly that food which it requires at any particular time. In this way a much larger cycle of attainments can be compassed than by the adoption of any programme or curriculum, however carefully drawn up. It is no good to teach what is not remembered; the strength of memory depends on attention, and attention depends upon interest. To teach without interest is to work like Sisyphus and the Danaides. Arouse interest if you can, rather by high means than by low means. But it is a saving of power to make use of interest which you have already existing, and which, unless dried up or distorted by injudicious violence, will naturally lead the mind into all the knowledge which it is capable of receiving. Therefore, never from the first force a child's attention; leave off a study the moment it becomes wearisome, never let a child do what it does not like, only take care that when its liking is in activity a choice of good as well as evil shall be given to it.

Mr Bain's writings on education, which are contained in some articles in the Fortnightly Review, and in two articles in Mind (Nos. v. and vii.) are extremely valuable. Perhaps the most interesting part of them consists in his showing what may be called the "correlation of forces in man" helps us to a right education. From this we learn that emotion may be transformed into intellect, that sensation may exhaust the brain as much as thought, and we may infer that the chief duty of a schoolmaster is to stimulate the powers of each brain under his charge to the fullest activity, and to apprise them in that ratio which will best conduce to the most complete and harmonious development of the individual.

It seems to follow from this sketch of the history of Conical-education that, in spite of the great advances which have been made of late years, the science of education is still far in advance of the art. Schoolmasters are still spending their best energies in teaching subjects which have been universally condemned by educational reformers for the last two hundred years. The education of every public school is a farcage of rules, principles, and customs derived from every age of teaching, from the most modern to the most remote. It is plain that the science and art of teaching will never be established on a firm basis until it is organized on the model of the sister art of medicine. We must pursue the patient methods of induction by which other sciences have reached the stature of maturity; we must discover some means of registering and tabulating results; we must invent a phraseology and nomenclature which will enable results to be accurately recorded; we must place education in its proper position among the sciences of observation. A philosopher who should succeed in doing this would be venerated by future ages as the creator of the art of teaching.

It only remains now to give some account of the very large literature of the subject.

The history of education was not investigated till the beginning of the present century, and since then little original research has been made except by Germans. Whilst acknowledging our great obligations to the German historians, we cannot but regret that all the investigations have belonged to the same nation. For instance, one of the best treatises on education written in the 16th century is Mulscher's Positions, which has never been reprinted, and is now a literary curiosity.

Mangeisdorf and Ruhkopf attempted histories of education at the end of the last century, but the first work of note was F. H. Ch. Schwarz's Geschichte der Erziehung. Other writers followed; but from the time of its appearance till within the last few years, by far the most readable and the most read work on the history of education was that of Karl von Raumer. Raumer, however, is too chatty and too religious to pass for "wissenschaftlich," and the standard history is now that of Karl Schmid. The Roman Catholics have not been content to adopt the works of Protestants, but have histories of their own. These are the very pleasing sketches of L. Kellner and the somewhat larger history by Stoos. When we come to writers who have produced sketches or shorter histories, we find the list in Germany a very long one. Among the best books of this kind are Fried. Dittner's Geschichte and Drose's Pedagogische Charakterbilder. An account of this literature will be found in J. Chr. G. Schumacher's paper among the Pedago- gische Studien, edited by Dr Reiss. For biographies the pedagogic encyclopedias may be consulted, of which the most useful is the Encyklopädie der studirenden und arbeitenden Ge-schichtler of K. A. Schmid, a great work in 11 or 12 vols. not yet completed, although the second edition of the early vols.
is already announced. The Roman Catholics have also begun a large encyclopedia edited by Rolfs and Pfister. No similar work has been published in France, but a Cyclopedia of Education in one volume has lately been issued by Dr. Arnold, and other writers are Kiddle and Scherr, and in this the are articles by English as well as American writers. In French the *Enquinte d'un systeme complet d' Education*, by Th. Fritz (Strasbourg, 1841), has a sketch of the history, which is as a sketch is worth notice. Jules Taras has written a useful little *Historie which would have been more valuable if it had been longer.

In English, though we have no investigators of the history of education we have a fairly large literature on the subject, but it belongs almost exclusively to the United States. The great work of Henry Barnard, the *American Journal of Education*, in 25 vols., has valuable papers on almost every part of our subject, many of them translated from the German, but there are also original papers on our old English educational writers and extracts from their works. This is by far the most valuable work in our language on the history of education. The small volumes published in America with the title of *History of Education* do not deserve notice. In England may be mentioned the article on education by Mr James Mill, published in the early editions of the *Encyclopaedia Britannica*, and Mr R. H. Quick's *most excellent Essays on Educational Reforms*, published in 1866. Since then Mr Leitch of Glasgow has issued a volume called *Practical Educationalists*, which deals with English and Scotch reformers, as well as with Comenius and Pestalozzi. Now that professorships of education have been established we may hope for some original research. The first professor appointed was the late Joseph Payne, a name well known to those among us who have studied the theory of education. The professorship was started by the College of Preceptors. At Edinburgh and at St Andrews professors have since been elected by the Bell Trustees.

Valuable reports as to the state of education in the various countries that possess a national system were presented to the English Schools Inquiry Commission in 1867 and 1868, by inspectors specially appointed to investigate the subject. The reports on the Common School System of the United States and Canada are by the Rev. James Fraser, on the Burgh Schools in Scotland by D. R. Fearon, and on Secondary Education in France, Germany, Switzerland and Italy, by Matthew Arnold, published in Parliamentary Papers [1867], 1867, and 1868. A preceding list of some useful books on education generally —

To the district will become insufficient, when the persons who would be the electors if there were a school board (in a borough by council), and (2) when they are satisfied that the managers of an elementary school are unwilling or unable to maintain it, and by its discontinuance the supply of education will be insufficient. The body of the Act describes the constitution, powers, duties, and revenues of school boards, as in the following brief summary:

1. **Constitution** — The school board is a corporation with perpetual succession and common seal, and power to hold land without limit in mortmain. It is elected by the burgesses in a borough, and by
the ratepayers in a parish, each voter having a number of votes equal to the number of vacancies having the right to give any number of such votes to any one candidate, and to distribute them as he pleases. The number of members varies from 6 to 15 as may be necessary. The London school board is elected under special regulations.

2. Powers and Duties — Every school board, for the purpose of providing sufficient public school accommodation, may erect school buildings, purchase, on lease, or otherwise acquire and improve schoolhouses and supply school apparatus &c., and purchase or take on lease any land or any right over land, fisheries, or minerals, for the purpose of erecting school buildings, or of carrying out the provisions of their district. They may provide or improve schoolhouses and supply school apparatus &c., and purchase or take on lease any land or any right over land, fisheries, or minerals, for the purpose of erecting school buildings, or of carrying out the provisions of their district. Sections 52 to 58 enable the board to pay the fees of poor children attending public elementary school other than their own, and Section 56 enables the board to pay the fees of poor children attending a public elementary school, if the parent or guardian refuses to pay the fees. The boards are to be elected by the ratepayer of the district in which they sit. The board may delegate their powers (except that of raising money) to managers. Any breach of these regulations may subject the board to be declared in default by the Education Department, who will then nominate a new board. The fees of children attending school boards are to be fixed by the board, with the consent of the Department, but the board may remit fees on account of poverty for such period not exceeding six months, and it is expressly declared that "such remission shall not be deemed to be partial relief" given to the parent. Further, free schools may be established under which the Education Department is satisfied that the poverty of the inhabitants is such as to render them necessary. Section 25 enables the board to pay the fees of poor children attending a religious elementary school, but "no such payment shall be made or refused on condition of the child attending any public elementary school other than as may be selected by the parent or guardian of the child, and no such payment shall not be deemed to be partial relief." This clause, which exists a vast amount of opposition in Parliament, was repealed by 39 and 40 Vict. c. 59 (see 1876).

3. Revenue of the board is to be paid from a fund called the school fund, constituted primarily by the fees of the children, moneys provided by Parliament, or raised by loan, or received in any other way, and supplemented, if necessary, by the rating authority. In providing buildings, &c., the board may borrow money so as to spread the payment over several years, not exceeding fifty years. (See, as to how, Elementary Education Act 1873, 1876.)

School boards may by a bye-law require the parents of all children between five and thirteen to send them to school, and it is a reasonable excuse, (1) that the child is receiving efficient instruction in some other manner, or (2) is prevented by sickness, or (3) that there is no public elementary school within such distance not exceeding three miles as the bye-laws may prescribe. Breaches of any such bye-law may be recovered in a summary manner, but the penalty shall not exceed five shillings including costs.

Finally, it is provided that in future no parliamentary grant shall be made to any school which does not come within the definition of "public elementary school in the Act of 1870." Such grants shall be made in respect of religious instruction, and shall not exceed in any case the income of the school from other sources. No connexion with a religious denomination is necessary, and no preference is to be given to a school on account of its being or not being a board school. Otherwise the minutes of the Committee of Council govern the proceedings of the grant, such minutes to be one month on the table of both Houses of Parliament before coming into force.

The Elementary Education Act, 1873, amends the Act of 1857 in several particulars not necessary to be specified here.

The Elementary Education Act, 1876, which came into operation on the 1st January, 1877, declares that it shall be the duty of the parent of every child (meaning thereby a child between the ages of five and fourteen) to cause such child to receive efficient elementary instruction in reading, writing, and arithmetic — the duty to be enforced by the orders and penalties specified in the Act. The employment of children under the age of ten, or over that age without a certificate of proficiency or of previous due attendance at a certified efficient school, is prohibited unless the child is attending school in accordance with the Factory Acts, or by permission under the Education Acts. Section 10 substitutes for section 25 of the Act of 1872 the following:

"The parent, not being a pauper, of any child, who is unable by reason of poverty to pay the ordinary fees for such child at a public elementary school, or any part of such fees, may apply to the guardians having jurisdiction in the parish in which he resides, and the parish council shall appoint such guardians or three of them to be guardians for the purposes of this section, to consider, in every case, whether the child shall be admitted to a public elementary school, on the payment of such portion of the fees as shall be determined by them to be practicable, so that the said fees shall be not more than threepence per week, or such part thereof as he or she is, in the opinion of the guardians, so unable to pay."

This payment subjects the parent to no disqualification or disability, and he is entitled to select the school. The following new regulations are made as to the parliamentary grant. A child obtaining before the age of eleven a certificate of proficiency and of due attendance, as in the Act mentioned, may have his school fees for the next three years paid for him by the Education Department — such school fees to be calculated as school-plain. The grant is no longer to be reduced by its excess above the incomes of the school, unless it exceeds 17s. 6d. per child in average attendance, but shall not exceed that amount except by the same sum by which the income of the school, other than the grant, exceeds it. Special grants may be made to places in which the population is small. Other clauses relate to industrial schools, administrative provisions, &c.

Scotland.—Previous to the Education (Scotland) Act of 1872, the public elementary education rested on the old parochial system, supplemented in more recent times by the parliamentary grants from the Committee of Council on Education. Under the old law the heritors in every parish were bound to provide a schoolhouse, and to contribute the schoolmaster's salary half of which, however, was legally chargeable on tenants. The Education Act of 1872 establishes for a limited number of years a Board of Education for Scotland, to be responsible to the Scotch Education Department of the Privy Council, on which its functions are ultimately to devolve. The board makes an annual report to the department.

A school board must be elected in every parish and burgh as defined in the Act. The number of members (between five and fifteen) is fixed by the Board of Education, and no teacher in a public school is eligible. The election is by cumulative vote, and disputed elections are to be settled by the sheriff. The school board is a body corporate. Existing parishes, burgh, and other schools, established under former Acts, are to be handed over to the school board.

The school board, acting under the Board of Education, shall provide a sufficient supply of school accommodation, and in determining what additional amount is necessary, existing efficient schools are to be taken into account, whether public or not. Provision is made for the transfer of existence of existing schools to the school board.

The clauses as to the school fund, and the power of the board to impose rates and to borrow money, are similar to those in the English Acts, and it is declared that sunk funds for the benefit of burgh or parish schools shall be administered by the board, and that the board shall be at liberty to receive any property or funds to be employed in promoting education. Schoolmasters in office at the passing of the Act are not to be prejudiced in any of their rights, but all future appointments shall be during the pleasure of the board, who shall assign such salaries and emoluments as they think fit.

Sections 56—69 relate to the qualifications of teachers. A principal teacher in a public school must possess a certificate of competency or an equivalent as defined in the Act.

Section 62 contains provisions for the maintenance by the school board of higher class public schools in burghs, which are as far as practicable to be released from the necessity of giving elementary instruction, so that the funds may be applied more exclusively to the instruction on the higher branches. And when by reason of an increase of school attendance or otherwise, the parents of a child are to be entitled to give the child a certificate of proficiency in the higher branches, it may be deemed to be a higher class school and maintained accordingly.

The following are the Acts relating to education in Scotland recited in the Education Act of 1872—Act of Scots Parliament, 1868 (1st of King William); 48 Geo. III. c. 54; and 2 Vic. c. 87, and 24 and 25 Vict. c. 107.
Parliamentary grants are to be made (1) to school boards, (2) to the managers of any school which is efficiently contributing to secular education. No grant shall be made in respect of (1) religious instruction, (2) new schools, not being public schools; unless it appears that they are required, regard being had to the religious belief of the parents of the children for whom they are intended, or other special circumstances of the locality. Section 68 is the conscience clause, and it may be mentioned that the preamble of the Act states that it is expedient that managers of public schools should be at liberty to continue the custom of giving instruction in religion to children whose parents do not object, with liberty to parents, without forfeiting any of the other advantages of the schools, to elect that their children should not receive such instruction. Section 69 imposes on parents the duty of providing elementary instruction for children between five and thirteen at the public expense. The parents shall pay to the headmaster a certain sum levied on himself or his family. Defaulters may be prosecuted, and persons receiving children into their houses or workshops shall be deemed to have undertaken the duties of parents with reference to the education of children. A certificate of the child's previous by an inspector protects the parent or employer from proceedings under the Act. Other clauses relate to the non-educational duties imposed by various Acts on schoolmasters (now transferred to registrars), and to the 'Schoolmasters' Wallet's Fund,' to which new masters are not required to contribute.

Ireland—The public elementary school system depends on grants made to the lord-lieutenant, to be expended under the direction of commissioners nominated by the Crown, and named the "Commissioners of National Education." The commissioners were incorporated by this name in 1845, with power to hold land to the yearly value of £40,000. The following statement, taken from the rules and regulations of the commissioners appended to their report for 1873, exhibits the leading points of the system as contrasted with that now established in England and Scotland.

"The object of the system of national education is to afford equal literacy and moral and separate religious instruction to children of all denominations, as far as possible in the same school, upon the fundamental principle that no attempt shall be made to interfere with the peculiar religious tenets of any description of Christian people. It is an earnest wish of Her Majesty's Government and of the commissioners that the clergy and laity of the different religious denominations should co-operate in conducting national schools.

The commissioners grant aid to either to vested schools (i.e., schools vested in themselves, or in local trustees to be maintained by them as national schools) or to non-vested (i.e., private schools), and the grant may be towards payment of salary or supply of books, or, in the case of vested schools, towards providing buildings.

The local government of the national schools is vested in the local patrons or managers thereof, and the local patron is the person who applies in the first instance to place the school in connection with the board, unless otherwise specified. The patron may manage the school by himself or by a deputy. If the school is controlled by a committee or vested in trustees, they are the patrons. A patron may nominate his successor, and in case of death, his legal representative if he was a layman, and his successor in office if he was a clerical patron, will be recognized by the commissioners. The local patrons have the power of appointing and removing teachers, subject to a rule requiring three months' notice to the teacher. Every national school must be visited three times a year by inspectors.

In visited schools, the commissioners do not in general make any conditions as to the use of the building after school hours; but no national school house shall be employed at any time, even temporarily, as the stated place of divine worship of any religious community, and no grant will be made to a school held in a place of worship. In all national schools there must be secular instruction four hours a day upon five days in the week. Religious instruction must be so arranged that each school shall be open to the children of all communions, that due regard be had to parental right and authority, and that accordingly no child shall receive or be present at any religious instruction of which his parents or guardians disapprove. In non-vested schools it is for the patrons and local managers to determine whether any and what religious instruction shall be given. In all national schools, the patrons have the right to permit the Scriptures to be read, and in all vested schools they must afford opportunities for the same, if the parents or guardians require it.

EDWARD, or EADWARD I, king of the Anglo-Saxons, was the eldest son of Alfred the Great, and succeeded his father, by the voice of the Witan, 26th October 901. He was then about thirty years of age, and had already in 893 distinguished himself by inflicting a disastrous defeat on the Danes at Farnham. His election to the throne was disputed by his cousin Ethelwold, who, having himself the Dunes of Northumbra, waged with varying success a civil war of four years' duration. It was brought to a close in 906 by Ethelwold's death in battle, when Edward concluded a peace with the West Anglians and Northumbrians. The pacification was not, however, of a very satisfactory nature, and was not of long continuance, for in 910 Edward "sent out a force of West Saxons and Mercians, who greatly spoiled the army of the north," and in 911 the Dunes, receiving large reinforcements from France, made repeated attacks on Wessex and Mercia. Against this enemy Edward and his sister Ethelfleda, who became "lady of Mercia" in 912, formed conjunct measures. Ethelfleda drove the Dunes from Mercia, and to secure her conquest erected the fortresses of Builgenorth, Stafford, Tamworth, and Warwick, while Edward, by adopting the same methods in East Anglia and Essex, gradually accomplished the complete subjugation of the Dunes. On the death of Ethelfleda in 922 he annexed Mercia to his own crown, and became king of all England south of the Humber. But this was not the whole result of his victories, for the Dunes of Northumbra, the Welsh, the Scots, and the Britons of Strathclyde, either from dread of his power or from desire for his protection, voluntarily chose him to be their "father and lord." He died in 925, inferior to his father in the higher moral and intellectual qualities, but not in common sense superior to his as a legislator and warrior, and under him the Anglo-Saxon rule attained a fame and influence to which it had never before made a near approximation.

EDWARD, or EADWARD II, known as the Martyr, an Anglo-Saxon king, succeeded his father Edgar in 925, at the age of about thirteen years. He was the elder son of Edgar, and is said to have been recommended by him as his successor, but the party in the state opposed to the monks supported nevertheless the claim of his younger brother Ethelred, son of Ealdred, and only seven years of age. The influence of Dunstan was, however, sufficiently great to overbear all opposition, and in a somewhat summary fashion he presented Edward to the Witan at Winchester, and consecrated him king. During his short reign the only circumstances worthy of notice are the quarrels between the two parties in the state, and the rapid decline of the authority of Dunstan and the monks. The death of Edward, which occurred in 978, was the result of a base act of treachery on the part of Ealdred. He was educated at Wareham when he was considered to be of an age for the duties of his office, and was stabbed in the back while partaking of hospitality before her palace gate.

EDWARD, or EADWARD III, king of the Anglo-Saxons, was born at Ips, Oxfordshire, probably in 1004. On the election of Sweyn to the throne of England in 1013, Emma with...
her husband and family took refuge in Normandy; and Edward, notwithstanding the marriage of Emma to Canute in 1017, continued to reside at the Normans' court, until he was recalled to England by Hardecanute in 1041. Hardecanute died in 1042, and "before the king was buried, all folk chose Edward to be king at London;" but partly from his own unwillingness to accept the crown, and partly from his aversion to the position of the Danish king, who came into England with Canute, his coronation did not take place until April 1043. The chief agent in overcoming his scruples, and in quelling all murmurs of opposition against his election, was Godwin the West Saxon earl, whose influence was at that time paramount in England. The exact nature of the relations between Godwin and Edward has been the subject of considerable discussion; but the most probable view of the matter is that, until after the marriage of Edward to Editha, daughter of Godwin, in 1045, these were on the whole cordial and friendly, but that gradually the king's preference of Normans to Anglo-Saxons, has necessary friendship with Lanfrc of Mercia and Siward of Northumbria, and his growing dread of Godwin's ambitious character, led to misunderstanding and distrust. It was, probably, at the instigation of Godwin that Edward, on his accession to the throne, deprived his mother Emma of her possessions, and caused her to live in retirement at Winchester, and that he banished from the kingdom the chief Danish partisans who opposed his election. For the first eight years his reign was comparatively tranquil, the only circumstances worthy of mention being a threatened insurrection between Godwin and the bishops, and a quarrel ensuing, several Normans were slain. The king, on hearing Eustace's account of the affair, without further inquiry commanded Godwin to chastise the town by military execution. Godwin demanded a trial; but the king, incited as it is said by Robert, archbishop of Canterbury, summoned a meeting of the Witan at Gloucester, not for the purpose of inquiring into the affair at Dover, but to pass judgment on Godwin for his conduct. Ultimately, Godwin was sentenced to leave the country and take refuge in Flanders. It was during his absence that William, duke of Normandy, visited England; and if this prince did not then receive the promise of the crown from Edward, his ambition to possess it and his hopes of success were doubtless confirmed by his visit. There seems to have been general regret at Godwin's absence; and encouraged by the assurances he received from England, he gathered a fleet, and uniting with Harold, appeared before London. The king endeavoured to oppose him, but was obliged to yield to the wishes of his subjects, and Godwin and his sons were reinstated in their possessions. When her father left England, Editha had been deprived of her property and sent to the royal abbey of Westminster, and the only wish was to be present at its consecration, which was to take place on the 25th December, but over-exertion on some previous festival days was too much for his remaining strength. His share in the ceremony had to be performed by deputy, and on the 26th December, 1066. It was his last wish that Harold should succeed him on the throne. The virtues of Edward, it has been said, were monastic rather than kingly. His aims were just and righteous, and he showed his interest in his subjects by the preparation of a digest of the laws of the kingdom, and by the repeal of the Danelaw, or war tax; but his weak character and his feeble interest in worldly matters caused the real government of the kingdom during his reign to be placed almost entirely in the hands of favourites. See Palgrave's History of the Anglo-Saxons, Green's History of the English People, and especially Freeman's Norman Conquest, vol. ii.

EDWARD I. (1239-1307), king of England, was the son of Henry III. of England, and of Eleanor, daughter of the count of Provence, and was born at Westminster, June 16, 1239. In 1253 he was named governor of Gascony in room of Simon de Montfort, with whom Henry was dissatisfied; and in 1254, by his marriage with Eleanor, daughter of Alphonso X. of Castile, he secured to the English for a time undisputed possession of that province. At the battle of Lewes, 13th May 1264, Edward, by the impetuosity of his attack, at first defeated the barons with great slaughter, but by his too great rashness in pursuit failed to give the king proper support in another part of the field, and was thus the cause ultimately of the utter rout of the royal forces. He was taken prisoner, but escaping by a clever stratagem, he joined with the earl of Gloucester, and inflicted a disastrous defeat on De Montfort and his sons at Evesham, August 3, 1265. In 1269, at the request of the Pope, he undertook a crusade to the Holy Land. He reached it in 1270, and in 1271 he captured Nazareth and massacred all the Turks found within its walls. In revenge, perhaps, for this act, an assassin, on June 12, 1272, stabbed him in three places with a poisoned arrow; but his vigorous constitution triumphed over his injuries and he completely recovered. In the same year his father died, and he was proclaimed king. He had arrived at Sicily when the news reached him, but instead of going direct to England, he crossed over to Italy, and thence into France, where in a tournament his followers quarrelled with those of the count of Chalon, and he slew the count in single combat. He landed in England August 2, 1274, and was crowned on the 19th. In October of the same year he issued writs to inquire into the state of the realm, and the next year there were passed the laws called the Statutes of Westminster, which reformed many of the abuses of the feudal system, secured freedom from undue influence in the election of sheriffs and other justices, and threatened with penalties certain oppressive acts on the part of the barons. In 1277 he conquered Wales and caused Llewelyn to sue for peace; but in 1280, a Welsh war again broke out, which continued till the death of Llewelyn in 1282. Edward's plan to obtain money for the expenses of this war, by summoning for consultation in 1283 representatives of the shires, the boroughs, and the church, was the germ of the English House of Commons, although the first properly constituted Parliament did not meet till 1295. A less creditable method of raising money was the banishment, in 1280, of the Jews from England, on condition that the clergy and laity submitted to a tax of a fifteenth. Two other important decisions were the consequence of his money difficulties — in 1297 he refused submission to the bull of Boniface VIII. forbidding the clergy to be taxed on their ecclesiastical revenue, and in 1299 he was obliged to confirm the charters conferring on the people the right to fix their own taxation. In 1290 Queen Eleanor died, and in 1293 Edward entered into negotiations for a marriage with Margaret, sister of Philip IV. of France; but on account of an act of treachery on the part of the French, these negotiations were broken off for a time, and the marriage did not take place till 1299. From 1295 the affairs of Scotland occupied his chief attention. In 1292 he had decided the claims of the candidates for the Scottish crown
in favour of Baliol, on condition that the latter acknowledged him as lord paramount, and on the breaking out of war with France he demanded his assistance. On Baliol's refusal, and on learning that he had entered into a treaty with France, Edward in 1296 captured Berwick, defeated the Scots at Dunbar, took the castles of Roxburgh, Jedburgh, Edinburgh, Dumbarton, and Stirling, and, receiving at Perth Baliol's unconditional surrender, sent him prisoner to the Tower. In 1297 Wallace headed a rebellion of the Scots, and defeated the English with great slaughter at the battle of Stirling bridge; but next year the Scots suffered an overwhelming defeat at Falkirk, and only prevented the further success of the English by laying waste their own country. In 1299 and 1300 Edward's attempts at invasion met with little success on account of opposition from his barons. In 1301 he invaded Scotland for the fifth time, but at the request of the king of France granted it a truce. In 1304 he compelled its submission, and exempted from the amnesty granted to the Scotch nobles Sir William Wallace, who was captured and executed in 1305. In 1307, to avenge Bruce's murder of Conyn and his attacks on the English, Edward resolved on a seventh invasion, and, though in great bodily weakness, determined to lead his army in person, but his almost unexampled labours had already undermined his vigorous health, and he died 7th July 1307, at the village of B urgh-the-Sands, on the fifth day of his march northwards from Carlisle. He had given orders that his dead body should be carried before the army until his enemies were conquered, but his son Edward made no endeavour to fulfil his wish. The body was escorted to Waltham, and was buried at Westminster on 27th October. In Edward were united in a rare degree both the physical and mental qualities of a great general; and he is one of the few English kings, and perhaps the first, who can lay claim to the higher qualities of statesmanship. The measures which he passed for the government of his own kingdom, and the concessions he made to the demands of his subjects, almost entitle him to be called the founder of England's constitutional freedom; while the far-seeing wisdom of his foreign policy was shown by his sacrificing his influence in France in order to quell the opposition to his authority in Scotland. The whole tenor of his reign was a continual attempt to secure the attainment of this end, and it is his highest title to memorable remembrance. His hardy manner of attaining his end, and the cruel punishments he exercised on those who sought to thwart his efforts, may be excused partly on account of the times in which he lived, and partly as arising from the just vexation of a stern and eager nature, and they are somewhat counter-balanced by the righteousness and clemency with which he governed Scotland at the periods when it was under his rule.

**EDWARD II.** (1284-1327), king of England, fourth son of Edward I. and of Eleanor, was born at Carnarvon, April 25, 1284, and became heir-apparent in 1285. His first title was earl of Carnarvon, but in 1301 he was created earl of Chester and prince of Wales. His personal character, and the whole tenor and tendency of his reign, may perhaps be best described as the opposite of those of his father. Though not the slave of any of the worst vices, and not without natural abilities, he was weak, indolent, and faithless, and his utter incompetence for the position in which fortune had placed him requires no other proof than the fate which finally overtook him. His first acts after the death of his father foreshadowed his future career. He at once recalled Piers Gaveston, a favourite whom his father had banished from the court, and created him earl of Cornwall, caused his father's body to be buried at Westminster, and, after rejoining the army for a few days, returned again to London, and for six years made no serious effort to prosecute the war with Scotland. Previous to his coronation he went to France to be married to Isabella, daughter of Philip II.; and by appointing Gaveston guardian of the kingdom during his absence, and loading him with honours and presents on his return, he roused the animosity of the nobles to such a height that it was only on his promising to agree to certain demands that might be submitted to him at a future Parliament, that they consented to his coronation. It took place 25th February 1308. Until the nobles rose in rebellion in 1312, and executed Gaveston at Warwick castle, the favourite formed a perpetual subject of disputes between the nobles and the king, and was alternately banished and recalled according to the king's exigencies. In 1311 Parliament confirmed the report of the "Committee of Ordnances" appointed to reform the abuses of the administration. The king nominally agreed to act in accordance with the report, but by a saving clause secured to himself full liberty to evade the principal enactments, the result of which was a series of quarrels with the nobles, becoming more serious each successive time, followed by reconciliations increasing gradually in bolderness till the end of his reign. Robert Bruce took full advantage of the internal difficulties of England, and in 1314 had reconquered the principal strongholds of Scotland with the exception of Stirling castle. For its relief Edward raised an army of 100,000 men, but suffered a runaway defeat at the battle of Bannockburn, 24th June 1314. Edward made no further effort of importance against the Scots till 1319, when he besieged Berwick, which Bruce had taken, but was compelled to raise the siege, and concluded a two years' truce with Scotland. After the death of Piers Gaveston, the place of favourite with the king was occupied by Hugh Despenser. He was banished by Parliament in 1321, but soon returned; and, provoked at this, the barons under Lancaster declared war, but were defeated and Lancaster executed in May 1322. In 1323 a fourteen years' truce was concluded with Scotland. In 1324 Edward was persuaded to send the queen to France in order to settle some disputes with the French king. She succeeded in her mission, but refused to return home, on account, she affirmed, of previous ill-treatment by her husband, although doubtless intrigues with Roger Mortimer had something to do with her refusal. From France she went to Flanders, and, raising a small army against the king, landed at Orwell in Suffolk, 23rd September 1326. The whole nation flocked to her standard, Despenser was executed, and young Edward was appointed guardian of the kingdom. In 1327, the king was formally deposed by Parliament, and his son elected in his stead. A plot was formed against the deposed monarch in the same year, and he was murdered with great cruelty at Berkeley Castle on the 27th September. (See the same writers for this reign as for the last.)

**EDWARD III.** (1312-1377), king of England, eldest son of Edward II. and of Isabella, was born at Windsor, November 13, 1312. He was appointed guardian of the kingdom October 26, 1326, and received the crown February 1, 1327. On the 24th January 1328 he was married to Philippa, daughter of the count of Hainault. During his minority the government of the kingdom was intrusted to a body of guardians with Henry of Lancaster as their head, but was virtually usurped by Roger Mortimer, until the king, irritated by his arrogance, caused him to be
Edward.

seized at Nottingham on the 15th October 1330, and conveyed to the Tower. He was executed at Tyburn on the 29th November. It is said to have been chiefly through Mortimer's influence that, on the 24th April 1326, a peace was concluded between England and Scotland, the chief provisions of which were that the Scots agreed to pay England the sum of £200,000, and that Edward agreed to recognize the independence of the Scotch crown. The treaty was very unpopular in England, and it is not surprising, therefore, that, when Edward Baliol in 1332 made his attempt to mount the Scotch throne, Edward III. gave him indirect assistance, and that after Baliol's destruction in 1333 an invasion of Scotland was resolved on. On July 19 Edward defeated the Scots at the battle of Haldon Hill, and receiving as the result of his victory the submission of the principal Scotch nobles, he annexed the whole of Scotland south of the Forth to his own crown, and allowed Baliol to reign over the remainder as titular king. Soon after, Baliol was again in fugitive, but was again aided by Edward to mount a nominal throne. After a short period of peace Edward in July 1336 ravaged and burned Scotland as far as Aberdeen, but growing complications with France compelled him in the same year to return to England. Though he professed to have a claim, through his mother, on the French throne against Philip of Valois, that claim was left in abeyance until several acts of aggression on the part of Philip brought about a rupture between the two kings. The count of Flanders, as Philip's instigation, had broken off commercial relations with England. French privateers were daily committing ravages on English commerce; Aquitaine was continually threatened by desultory attacks; and Philip, though he hesitated to accept the responsibility of being the first to declare war, scarcely attempted to conceal his intentions to throw that responsibility on Edward. Edward sailed for Flanders July 16, 1338, and at Coblentz endeavoured to seize the Dauphin, but was unsuccessful. In 1346 he set sail on the expedition which resulted in the battle of Sluys, at which the French agreed to pay for King John a ransom of three million crowns, and Edward renounced his title to the throne of France, but retained his full sovereignty over the whole of the ancient duchy of Aquitaine, the counties of Ponthieu and Guines, and the town of Calais. Peace was again broken in 1369 by Charles of France, and when he concluded a truce with England in 1375 all of France that remained in Edward's hands was Boulogne and Bordeaux in the south, and Calais in the north. The last years of Edward's reign form a sad and gloomy close to a career which had had a vigorous and energetic commencement, and had afterwards been rendered illustrious by great achievements. His empire in France was virtually overthrown; the vast expenditure which had had such a fruitless result was sorely burdening his subjects, and awakening increasing discontent; and he himself, through the gradual decay of his mental faculties, had become a mere tool in the hands of Alice Perrers and of ministers whose only aim was their own aggrandizement. In 1367 the "Good Parliament" virtually seized the helm of the state from the hands of the king and as steadily raised an army Alice Perrers to swear never to return to the king's presence, suspended the munsters Latimer and Lyons, protested against the means then adopted for raising taxes, and demanded a vigorous prosecution of the war. The Black Prince was the chief agent in urging these reforms, but his death, in the midst of the Parliament's deliberations, for a time rendered almost abortive the good work he had begun. Edward died 21st June 1377. The splendour of his reign belongs properly rather to the people than to the monarch. Both in his home and foreign relations he showed considerable prudence and sagacity, and he may be allowed the credit of having endeavoured as much as possible to keep on good terms with his subjects; but under him the progress of constitutional reform was due either to his money difficulties or to events entirely beyond his control. Although endowed with high courage and daring, there is no proof that he possessed more than average ability as a general. His expeditions were planned on a scale of great magnificence, but he entered on his campaigns without any definite aim, and his splendid victories were mere isolated achievements, won partly by good fortune, but chiefly by the valor of Welsh and Irish yeomen and the skill of English archers.

See_History of Edward the Third, by W. Longman (1860); Edward III., by Rev. W. Warburton, M.A. (1783); Pearson's England in the Fourteenth Century (1876), and essay on Edward III., by E. A. Freeman (Essays, first series).

EDWARD IV. (1441-1483), king of England, was the second son of Richard duke of York, and was born at Bœu, April 29, 1441. His father was appointed protector of the kingdom during the incapacity of Henry VI., and having in 1460 laid claim to the throne as a descendant of Edward III., was named by Parliament successor of Henry VI. on condition that he allowed Henry to retain his throne. As an heir had been born to the king, it was only natural that Queen Margaret should seek to resist this proposal. She laid claim to the throne against the duke of York, and he was defeated and slain at the battle of Wakefield, December 30, 1460. Edward, who was at that time in Wales, on hearing of his father's death resolved to avenge it, and gathering a mixed army of Welsh and English, defeated the earl of Pembroke and Ormond at Mortimer's Cross in Hereford, February 7, 1461. On February 17, Queen Margaret defeated the Yorkists at St Albans; but Edward, notwithstanding her victory, having united his forces with those under Warwick entered London, and, being received by the citizens with loud shouts of welcome, was proclaimed king 4th March 1461. But he could not permit himself to enjoy his dignities in idle security. King Henry had escaped and joined the army of the queen, which, having withdrawn to the north,
was to the number of about 60,000 encamped at Towton, about eight miles from York. Here Edward and Warwick met the queen's forces, and a battle of great obstinacy ensued, which, notwithstanding the arrival of a reinforcement to Margaret in the middle of the battle, ended in her utter defeat. Henry and Margaret fled to Scotland, and on the 28th June Edward was crowned at London. Margaret afterwards escaped to France, from which country in 1462 she made two separate attempts to retrieve the fallen fortunes of her house, but these, as well as one made by Henry in 1464, proved utterly abortive. In May 1461 Edward was secretly married to Elizabeth, daughter of Richard Woodville, Lord Rivers, and widow of Sir John Gray; and having in the September following publicly acknowledged her as his queen, he grossly disappointed and displeased his chief supporter, the earl of Warwick, who had been negotiating for the marriage of Edward with the sister of Louis XI. of France. Though from this time secretly bending all his energies to accomplish Edward's overthrow, Warwick skilfully concealed not only his intentions but even his share in overt acts; and it was not till 1469 that receiving intelligence of the success of an insurrection secretly fomented by him in Yorkshire, he showed his hand by taking the king prisoner near Coventry. Shortly after, Edward either escaped or was allowed his freedom, and in 1470, he defeated the rebels near Stamford, and compelled Warwick to make his escape to France. Here the earl, through the good offices of Louis, was reconciled with Queen Margaret, and agreed to invade England in behalf of her husband. Landing at Doutmouth, he soon had an army of 60,000 men. Edward, taken by surprise and unable to raise a force sufficient to oppose him, fled to Holland; and Warwick, having released Henry, again got him acknowledged king. Edward in his turn adopted the tactics that had been successful against him. In 1471 he landed at Ravenspur, and professing at first to resign all claims to the throne, and to have no further aim than merely to recover his inheritance as duke of York, he soon collected sympathizers, and then, throwing off all disguises, issued proclamations against Henry and Warwick. He marched without opposition direct to London, and after entering it and taking Henry prisoner, advanced against the army which had been collected to oppose him. The encounter took place at New Barnet, April 14, when the party of Warwick were defeated and Warwick himself was slain. On the same day Margaret with her son Edward, now eighteen years of age, had landed at Weymouth, but on May 4 she was defeated at Towkesbury and taken prisoner. Her son either perished in battle, or was slain shortly after by the order of the king; and her husband Henry died in the Tower on May 21, the evening of the day on which Edward re-entered London. Secure at home, Edward now turned his thoughts on foreign conquest. In 1475 he formed an alliance with Charles of Burgundy against Louis, but on landing on the Continent with a large army he learned that the duke and Louis had come to an understanding, and prudence compelled him to enter into a seven years' treaty with the power he had hoped to conquer. Shortly after this, the duke of Burgundy having died, Clarence, the brother of Edward, wished to marry Mary, the duke's daughter and heiress; but Edward, perhaps on account of chargin at the former defeats of her father, refused his consent to the suit. Exasperated at his brother's conduct, Clarence took no pains to conceal his anger, and Edward thought it proper to impeach him of treason before the House of Lords. He was condemned to death, February 7, 1475, and on February 17 was executed in the Tower, but with so great secrecy that the manner of his death is unknown. Edward died April 9, 1483. The beauty of his person and the freedom of his manners rendered Edward a great favourite with the lower and middle classes, but there appears to have been little in his character to awaken real esteem. He had certainly an ability for subtle scheming and intrigue, but his memory was clouded by a constant agitation with no act conferring any benefit of importance on his country, and it is tarnished by several deeds of ruthless cruelty, and by the helpless self-indulgence into which he sank during his later years. On account of the unsettled nature of the country during his reign, the influence of Parliament on the affairs of the kingdom became virtually suspended, while the antipathy and contents between the two parties of the nobles made it almost a necessity that that party which supported the king should be unable to present any strong resistance against undue exercise of authority on his part. The result was the inauguration of that form of despotism known as the New Monarchy.

EDWARD V. (1470-1483), king of England, was the son of Edward IV. and of Elizabeth, and was born in the sanctuary of Westminster Abbey, November 4, 1470. As soon as Edward IV. was dead his brother Richard, duke of Gloucester (see Richard III.), acting so far in accordance with the late king's wishes, secured possession of the person of the young king, and was appointed by Parliament protector of the realm. He had previously arrested Earl Rivers, the young king's uncle, and Lord Richard Gray his half-brother, and his next step was to accuse Lord Hastings, president of the royal council, of designs on his life, and to have him executed almost immediately afterwards on Tower Green. The way being now cleared for a full declaration of his designs, he caused it to be decided at a meeting of the Lords and Commons that the marriage of Edward IV. had been invalid on account of the existence of a precontract; and, receiving a petition to act in accordance with this decision and assume the crown, he after a very slight reluctance consented to do so. Edward V. and his brother were confined in the Tower. Shortly after it was known that they were dead, but though it was the general conviction that they had been murdered, it was not till twenty years afterwards that the manner of their death was discovered. Brackenbury, the constable of the Tower, had refused to obey the command of Richard to put the young princes to death, but complied with a warrant ordering him to give up the keys of the Tower for one night to Sir James Tyrrel, who had agreed to provide for the accomplishment of the infamous act. He gave admittance to two assassins hired by himself, who smothered the two youths under pillows while they were asleep.

For Edward IV. and V see Great's Short History of the English People, the Houses of Lancaster and York, by James Gardiner, and "Konig Richard III." in Paul's Allgemeine Geschichte der Welt.
legislation in favour of Reforma1tion principles. Though England was in a somewhat unsettled state, this did not prevent him from planning an expedition against Scotland, on account of that power refusing to fulfil a former treaty by which a marriage had been agreed upon between Mary Queen of Scots and Edward. He defeated the Scots at the battle of Pinkie Cleugh, September 10, 1547, and next year captured Haddington; but, on account of the illness which he caught there, he was unable to give further attempts against Scottish independence. His brother, who had been created Lord Seymour of Sudeley and made lord admiral of England, was suspected of being at the head of a plot to overturn his authority, and on account of his eccentricities admitted as much as was sufficient to crimiuate himself, although he refused to answer in regard to the more serious charges. In the House of Lords a bill was framed against him which passed the House of Commons almost unanimously, and, it being assented to by the king shortly afterwards, he was executed on Tower Hill, March 20, 1549. In the following summer the distress consequent on the depreciation of the currency and the wasteful expenditure of the court awakened a general discontent, which in different parts of the kingdom broke out in open insurrection. The protector, instead of repressing the rebellion by vigorous measures, gave con­ siderable concessions to the demands of the populace, his sympathy with whom he openly admitted. By such an avowal he necessarily alienated the nobility, and they yielded, on Tower Hill, January 22, 1552. The king, who, except

Edward preva1led over the strong objections of the judges, and letters patent being drawn out of the succession to the throne on the ground of their illegitimacy, and nominating as his successor Lady Jane Grey, who was married to the duke's eldest son. The arbitrary urgency of Northumberland and the religious obstinacy of Edward prevailed over the strong objections of the judges, and letters patent being drawn out in accordance with the king's wishes, passed under the Great Seal, and were signed by the chief nobles, including, although only after repeated endeavours to alter Edward's determination, Cranmer, archbishop of Canterbury. Edward died July 4, 1553. There were some suspicions that his death had been hastened by Northumberland, but although his malady showed at last some symptoms of poisoning, it is now believed that these were caused by accidental administrations of overdose of mineral medicine. The fact that Edward died makes it impos­sible to form a confident estimate of his character and abilities. The exceptional talent which he manifested in certain respects may have been due largely to the

E D W A R D
only charitable to suppose, partly to the irritation of ill health, and possibly to chagrin arising from the presentiment that the English power in France was now on the wane, was the one blot on his fair fame. It closed upon his military career, for he was compelled to retire in 1837, by the advice of his physicians, to return to England. From this time his constitution was utterly broken, but he lingered on to witness the loss of his duchy to England, and also to originate the measures of the "Good Parliament," although his death prevented their completion. He died at Westminster, 8th June 1876. He was buried at Canterbury Cathedral, where his maled dictus may still be seen.

EDWARDES, SIR HERBERT BENJAMIN (1819-1868), major-general in the East Indian army, one of the noblest names on the roll of the soldier-statesmen of the British Indian empire, was born at Frodsham, in Cheshire, November 12, 1819. The family was of high standing. Sir Herbert's father was Benjamin Edwardes, rector of Frodsham, and his grandfather Sir John Edwardes, baronet, eighth holder of the title, which was conferred on one of his ancestors by Charles I in 1644. After receiving his early education at a private school, he was sent to King's College, London, to complete his studies. Through the influence of his uncle, Sir Henry Edwardes, he was nominated in 1840 to a cadetship in the East India Company; and on his arrival in India, at the beginning of 1841, he was posted as ensign in the First Bengal Fusiliers. He remained with this regiment about five years, and during this period gave proof of that "great capacity for taking pains" which is the characteristic of genius. He mastered the lessons of his profession, obtained a good knowledge of Hindustani, Hindi, and Persia, and attracted the attention of the political and literary ability displayed in a series of letters which appeared in the Delhi Gazette. In November 1845, on the breaking out of the first Sikh war, Edwardes was appointed aide-de-camp to Sir Hugh (afterwards Viscount) Gough, then commander-in-chief in India. On the 15th of the following month he served at the battle of Moodkee, and was severely wounded. He soon recovered sufficiently to resume his duties, and fought by the side of his chief at the decisive battle of Solan (February 10, 1846), which closed the war. He was afterwards appointed aide-de-camp to the commissioners of the Trans-Sutlej Territory; and in January 1847 was named first assistant to Sir Henry Lawrence, the resident at Lahore. Lawrence became the great exemplar of the young hero, who looked up to him with the affectionate reverence of a disciple and a son, and in later years was accustomed to attribute to the influence of this "father of his public life" whatever of great or good he had himself achieved. He took part with Lawrence in the suppression of a religious disturbance at Lahore in the spring of 1846, and soon afterwards assisted him in reducing, by a rapid movement to Jamoom, the conspirator Imamuddin. In the following year a more difficult task was assigned him,—the conduct of an expedition to Bunnoo, a tributary Afghan district, in which the people would not tolerate the presence of a collector, and the revenue had consequently fallen into arrear. By his rare tact and firmnes of purpose, Edwardes succeeding in completely conquering the wild tribes of the valley without firing a shot, a victory which he afterwards looked back upon with more satisfaction than upon other victories which brought him more renown. His fiscal arrangements were such, as to obviate all difficulty of collection for the future. In the spring of 1848, in consequence of the murder of Mr Vaas Aclnew and Lieutenant Anderson at Mooltan, by order of the Dewan Moolraj, and of the raising of the standard of revolt by the latter, Lieutenant Edwardes was authorized to march against him. He set out immediately with a small force, occupied Leen on the left bank of the Indus, was joined by Colonel Cortlandt, and, although he could not attack Mooltan, held the enemy at bay and gave a check at the critical moment to their projects. He won a great victory over a greatly superior Sikh force at Kynyre (June 18), and received in acknowledgment of his services the local rank of major. In the course of the operations which followed near Mooltan, Edwardes lost his right hand, by the explosion of a pistol in his belt. On the arrival of a large force under General Whish the siege of Mooltan was formed, but was suspended for several months in consequence of the desertion of Shere Singh with his army and artillery. Edwardes distinguished himself by the part he took in the final operations, begun in December, which ended with the capture of the city, January 4, 1849. For his services he received the thanks of both houses of parliament, was promoted major by brevet, and created C.B. by special statute of the order. The directors of the East India Company conferred on him a gold medal and a good service pension of £100 per annum. After the conclusion of peace Major Edwardes came to England for the benefit of his health, married during his stay there, and wrote and published his fascinating account of the scenes in which he had been engaged, under the title of A Year on the Punjab Frontier in 1848-1849. His countrymen gave him fitting welcome, and the university of Oxford conferred on him the degree of D.C.L. In 1851 he returned to India and resumed his civil duties in the Punjab under Sir Henry Lawrence. In November 1853, he was entrusted with the responsible post of commissioner of the Feshawur frontier, and thus he held when the Mutiny or Sepoy War of 1857 broke out. It was a position of enormous difficulty, and momentous consequences were involved in the way the crisis might be met. Edwardes rose to the height of the occasion. He saw as if by inspiration the facts and the need, and by the prompt measures which he adopted he rendered a service of incalculable importance, by effecting a reconciliation with Afghanistan, and securing the neutrality of the Amur and the tribes during the war. So effective was his procedure for the safety of the frontier that he was able to raise a large force in the Punjab and send it to cooperate in the siege and capture of Delhi. In 1859 Edwardes once more came to England, his health so greatly impaired by the continual strain of arduous work that it was doubtful whether he could ever return to India. During his stay he was created K.C.B., with the rank of brevet colonel, and the degree of LL.D. was conferred upon him by the university of Cambridge. Early in 1862 he again sailed for India, and was appointed commissioner of Ambala and agent for the Cis-Sutlej states. He had been offered the governorship of the Punjab, but on the ground of failing health had declined it. In February 1866, he was compelled finally to resign his post and return to England. A second good service pension was at once conferred on him; in May 1866, he was created K.C. of the Star of India, and early in 1868 was promoted major-general in the East India army. It was known that he had been for some time engaged on a life of Sir Henry Lawrence, and high expectations were formed of the work, but he did not live to complete it. He died in London, December 23, 1868. Sir Herbert Edwardes was a singularly loyal and devoted public servant, and was generally beloved by his personal friends, and was generous and unselfish to a high degree. He was also a man of deep religious convictions.
and naturally desired and hoped for the evangelization of India. But his zeal was under the restraint of knowledge, and he knew how to reconcile private separation with public duty. When Sir John Lawrence, he advocated toleration for the native religious systems, and at the same time deprecated Government support of them in any way. "India," says a writer in the Pall Mall Gazette, "has produced many great men, some of whom have done more for their country; but there were few upon whom the stamp of genius was more widely impressed than upon Herbert Edwards." The life of Sir Henry Lawrence was completed by Mr Harman Mervale, and was published in 1873.

EDWARDS, BAYRN (1743–1800), the well-known historian of the West Indies, was born at Westbury, in Wilts, on the 21st of May 1743. His father died in 1756, and his education and maintenance were undertaken by his maternal uncle, Zachary Bayly, a wealthy West Indian merchant. He had been placed by his father at the school of a dissenting clergyman in Bath, where he received a careful training in English composition; his uncle's agent, however, removed him to a French boarding school in discovering that he had received no instruction in classics. Edwards went out to Jamaica to join his uncle, in whom he seems to have found everything he could desire,—the most enlightened mind, the sweetest temper, and the most generous disposition. To this was added a truly patriotic regard for himself which was returned with all the warmth of filial affection. His uncle, finding him possessed of literary talents, but deficient in classical acquirements, engaged a Mr Teale, a clergyman and formerly master of a free grammar-school, as resident tutor for him. The relationship proved a very agreeable one to both teacher and pupil, who expressed himself with moderation and affection.

In 1755, however, that he published his great work, on which he had been many years engaged, entitled History, Civil and Commercial, of the British Colonies in the West Indies, 2 vols. 4to. On the question of slavery and the slave trade he naturally took the planter's view, but he expressed himself with moderation and candour. In 1796 he published, in one volume quarto, a History of St Domingo, which had then excited a deep interest, on account of the insurrection of the slaves, and the consequent establishment of an independent negro government. In 1801 a new edition of both these works was published, in three vols 8vo, under the general title of History of the West Indies. A fifth edition issued from the press in the year 1819. When Mungo Park, returned from his celebrated journey in Africa, Edwards, from his oral information, drew up a report of it, which was submitted to the African Society, and published in their Transactions.

In 1766 he took the principal towns in Holland, and two years afterwards travelled in Norway and Sweden. In 1719 he went to Paris for the purpose of studying its natural history collections, and during his stay in France he made two journeys of a hundred miles each, the first to Châlons in Champagne, and the second on foot to Orleans and Blois. On his arrival in England he closely pursued his favourite study of natural history, applying himself to drawing and colouring such animals as fell under his notice. Birds first engaged his particular attention, and having purchased some of the best pictures of them, he made a few drawings of his own, which were admired by the curious, who encouraged the young naturalist by paying a good price for his early labours. In 1731 he made an excursion to Holland and Brabant, where he collected several scarce books and prints, and had an opportunity of examining the original pictures of several great masters, at Antwerp, Brussels, Utrecht, and other cities. In December 1733, by the recommendation of Sir Hans Sloane, the president of the college of physicians, he was chosen librarian to that body, and had apartments assigned him in the college. Here he had the opportunity of a constant recourse to a valuable library filled with scarce and curious books on the subject of natural history, which he so assiduously studied. By degrees he became one of the most eminent ornithologists in his own or any other country. He published the first volume of the History of Birds in 1743, a second volume in 1747, a third in 1750, and a fourth in 1751. In 1758 he continued his labours under a new title, that of Gleanings of Natural History. A second volume of the gleanings was published in 1760, and a third in 1764. The two works contain engravings and descriptions of more than six hundred subjects in natural history not before described or delineated. He likewise added a general index in French and English, which was afterwards perfected with the Linnaean names by Linnaeus himself, who frequently honoured him with his friendship and correspondence. In 1756 he received the gold medal of the Royal Society, given annually on St Andrew's day to the author of any new discovery in art or nature. He was, a few years afterwards, elected fellow of the Royal Society, and of the Society of Antiquaries, London, and also a member of many of the academies of sciences and learning in different parts of Europe. After the publication of his last work, having arrived at his seventieth year, and finding his sight beginning to fail, and his hand losing its wonted steadiness, he retired from public employment to a little house which he had purchased at Plaistow. The conversation of a few select friends, and the perusal of a few select books, were the amusements of the evening of his life; and now and then he made an excursion to some of the principal cities in England, particularly to Bristol, Bath, Exeter, and Norwich. His general health began to fail some years before his death, which took place on the July 23, 1773.
or, Connecticut, October 5, 1703. He was the  

a family of eleven children, of whom four were  

himself. Even in his very early years the religious  

communicated to him by his parents seems to  

god a large share of his interest, and to have  

strong influence on his character. In a state  

religious views in youth, he says, "I had a  

concerns and exercises about my soul from my  

and also, "from my childhood up my mind  

full of objections against the doctrine of God's  

"In his eighth or ninth year he experienced,  

"two remarkable seasons of awakening;" but  

ions against the doctrine of God's sovereignty  

to trouble him more or less until about his 17th  

year," he says, "I seemed to be convinced and  

led to this sovereignty of God, and his just  

eternally disposing of men, according to his  

pleasure, but never could give an account how or  

since I was convinced of it. I least imagined at  

a long time after, that there was any extra  

fluence of God's Spirit in it." Until he entered  

education was conducted by his father, with the  

assistance of his elder sisters. At the age of six  

the study of Latin, and in that language, as well  

and Hebrew, he attained to considerable  

y. In September 1718 he entered Yale College.  

his B.A. degree in 1720, but with a view to prepara-  

the ministry he continued his residence at college  

additional years. In 1718 he read Locke on the  

Understanding, and it was from its perusal that  

passion for abstract thought was first kindled.  

red that it had afforded him "far higher pleasure  

most greedy miser finds when gathering up hand-  

and gold from some newly discovered treasure."  

licensure to preach in 1722, and in August of  

on the invitation of a number of ministers in  

land, he went to preach to the Presbyterians in  

, where he continued eight months. He was in-  

the congregation to continue with them per-  

but on account of doubts as to his future use-  

that particular sphere, he declined their invitation,  

and to his father's house at East Windsor. Here he  

ed his studies in theology and metaphysics till June  

then he was appointed tutor in Yale College. About  

he completed the series of seventy resolutions  

for the ministry, and designed to give his own  

and life." No 11 of these may  

ioned as specially characteristic: "Resolved, when  

of any theorem in divinity to be solved, immediately  

but I can towards solving it, if circumstances do  

. He resigned his tutorship in September 1729,  

aving an invitation from Northampton to become  

and successor to his grandfather, the Rev. Samuel  

d, and in February 1727 he was ordained to that  

In the following July he was married to Sarah,  

of the Rev. James Prenceport, of New Haven. He  

Northampton till June 22, 1750, when, on  

of a dispute that had arisen from an attempt on  

it to prohibit some of the younger members of his  

ation from perusing certain books, which in his  

were obscene, he found himself compelled to resign.  

On learning of his resignation some of his  

in Scotland advised him to settle in that country,  

was also invited to a church in Virginia, but he ac-  
in preference to either invitation the proposals  
to him by the "Society in London for Propagating  

spel in New England," that he should become  

nary to the Houssamuck Indians, who were settled  

bridge, Berkshire Co., Massachusetts. The nature  

work now left him in possession of considerable  

leisure, of which he made use to such advantage that,  

within the six years of his residence at Stockbridge, he  

completed four of his principal treatises, including that on  

the Freedom of the Will, which was published in 1741.  

On account of the fame which this work acquired for him he  

was in 1757 called to succeed President Burr of Princeton  

College, New Jersey. He was installed February 16,  

1758, but was scarcely spared to enter upon the perfor-  

ance of his duties. On account of the prevalence of  

small-pox in the neighbourhood, he submitted to inocu-  

ation and the disease taking an unfavourable turn, he died on  

the 28th March. Edwards says of himself that he possessed  

"a constitution in many respects peculiarly unhappy,  

attended with fixed solidity, vapidity, error, and mueh  

and a low tide of spirits, often occuring a kind of  

childish weakness and scepticism of speech, presence,  

and demeanour." Notwithstanding this unhappy constitu-  

tion, he was throughout life a laborious student, often  

prosecuting, pen in hand, his arduous metaphysical  

researches for thirteen hours daily. As an orator he some-  
times held not only the feelings but the intellects of  

hearing completely under his sway. The extraordinary  

fluence which he thus exercised was not due to any  

personal advantages, for even when his language conveyed  

meaning without ambiguity, it did so not with  

mark of arrangement which is usually one of the  

chief elements of successful oratory, but in a bald, even  

a lumbering and awkward, manner. His eloquence was simply  

intense moral earnestness, expressed in the form of what, in  

more senses than one, might be called "merciless logic."  

His writings present a very remarkable conjunctural  

of apparently contradictory qualities, a conjunction attribut-  
able partly to a peculiar combination of natural mental  

characters, and partly to a habit of soberness which  
rendered him almost completely ignorant of the predominant  
tendencies of contemporary thought, and placed him almost  

beyond the reach of any external influences fitted to aid him  
in freeing himself from the shackles of past systems.  
The outstanding features of his character were undoubtedly  
his sense of reverence and his passion for ratiocination. In  
these respects these two opposite characteristics combined  
produce a harmonious result, namely, to impress him with  
an almost overwhelming conviction of the claims of duty.  
His awe of the Supreme Power was in one aspect of such  

nature as to seem consistent only with the grossest  

upravention, but from the very fact that it was the awe of  

an intellect, within the sphere of logic, so keen and  

penetrating, it was necessarily a moral awe, an awe which  

intensified that sense of duty whose requirements his  

logical faculty revealed with a distinctness which admitted  
of no fallacy or evasion. It was his overwhelming convic-  
tion of duty which gave to his system, theological, moral,  
and metaphysical, what unity it possessed. That unity is,  
however, nothing more than seeming, the positive and  

negative elements are held apart in different spheres; if  
they were brought into contact the necessary result  
would be an utterly destructive explosion. The basis of his  
whole system is the "sovereignty of God;" and of his  
conviction of God's "sovereignty" he tells us that of how  
by what means he arrived at it he could give no account.  
This mysterious and unaccountable conviction he however,  
endeavours to justify by a protracted logical process, with-  
out being at all conscious of any incongruity between means  
and end. This unconsciousness is due to the fact that the  
strength of his original conviction prevented him from dis-  
cerning the real difficulties he had to surmount. We have  

VII. 87
thus presented to us the spectacle of a mystic endeavoured to
express his belief by a mere process of reasoning, almost mathematical in its cold and definite precision and in its rigour. It is quite possible that his strong pre-
positions would in any case have prevented him from
exposing their true importance the new problems that
were beginning to appear on the horizon of con-
temporary thought, but, so far from having given these
problems the attention necessary in order to understand
them, he was scarcely aware of their existence. The
impulse he received from Locke's essay On the Human
Understanding did not lead him to seek full acquaintance
with the whole circle of the philosophical speculation of his
time,—partly no doubt because his circumstances prevented
him from doing so, but partly also because he had a strong
bias towards the pursuit of solitary trains of thought. In
him, he writes in the Freedom of the Will he confesses having
never read Hobbes; and although he mentions in a
letter having read one of Hume's works, this would appear to
have been subsequent to the publication of the
essay On the Freedom of the Will, and its purport does not
seem to have impressed him with any idea of its author's
exceptional metaphysical ability, for he merely says of it
and of some other books, "I am glad of an opportunity to
read such corrupt books, especially when written by men
of considerable genius, that I may have an idea of the
notions which prevail in our country." He was scarcely
conscious of the presence of the new influence which was
then stirring the stagnant waters of speculation; but
it certainly influenced him unconsciously, and compelled him
to check his vague unrest by more steadfastly clinging to his
old convictions. He succeeded in doing so, but without
the exercise of constant watchfulness, for, apart from any
immediate external influence, his strong and eager logical
faculty seems often as if bent on carrying him beyond the
bounds of traditional opinion, and requires frequently to be
pulled up with a certain measure of abruptness.

The theological system of Edwards emphasized all the sternest
features of Calvinism and revealed them in strong relief. Calvinism
in its original form was founded on extreme statements regarding
"God's sovereignty" and "man's depravity by nature," but the
inferences implied in these statements are set forth by Edwards
in his system as excellent and regressive ideas with a logical
consistency not previously attempted. The
argument he employs to establish his propositions is unanswerable as
a mere argument of logic, but he shows conclusively that their
truth is, if anything, rather worse than his own; but
when he seeks to go beyond this very circumscribed sphere he
falls into a lattice of self-contradictory assumptions, and
often abstrings a thing that seems to present itself is only a choice of two evils,—either
to remain for ever utterly bewildered by the contradictory paths which open up before him, or by selecting one of them to wander irresolu-
tively beyond the bounds of what he recognizes as orthodox. We
have an example of this when he endeavours to prove that
though men are born utterly depraved, God is not the author of
depraity. His theory is that Adam was originally possessed of
two principles,—one which may be called natural, being the
"primary principles of human nature," or as it is called in Scripture the
"flesh," and another called the supernatural principle, or as in Scripture
the "divine nature." When Adam ate of the tree of forbidden
fruit the divine nature was withdrawn from him, and thus his nature
became corrupt without God infusing any evil thing into it. "So," says Edwards, "does the nature of his posterity; they come into the world
with the flesh, and entire only in the image of natural and inferior
principles." Here it will be seen, not only that Edwards appears to
very little advantage as a reasoner, but that he is in
imminent peril of overthrowing the central positions of his own
system; for, first, if to represent an as a merely negative quality
in any degree solves the difficulty of God being sinless, it does so at
the expense of denying to it a real existence; and, secondly, to
represent man as born into the world "with flesh" entirely destroys
the distinction, so essential to the system, between "natural
and supernatural" principles. He soon, however, escapes back to his old
position although not by the way he set out. "If any," he says,
"should object that this is an essential difference of original righteousness be
considered as an established course of nature, then who
the principles of holiness, when restored by divine grace, also com-
nounced to posteriority, I answer, the divine law and establishment of
the Author of nature are precisely settled by Him as wise and
limited by His wisdom." The moral theory of Edwards is but a corollary from his
theological system. Virtue he places in love or benevolence in
being in general, or more specifically in a "disposition to benevolence
towards being in general," for he does not mean to affirm
that every virtuous act must have unceasing universal existence
as its immediate object," but merely that: "Such a disposition towards
ew objects or beings is of the nature of true virtue, but such
can rise from a generally "benevolent temperament." This love
cannot be primarily a "love of complacency," that is, a
having any regard to excellence in the object, for that "would
beget in a circle, and the same as saying that virtue consists
in love to virtue," and that it cannot consist in "gratitude, or
being benevolent to another for his benevolence to him," be
"thus implies the same "inconstancy," consequent to the
first object of a virtuous benevolence is being simply con-
and, if being simply considered, then being in general.
However, "second object of a virtuous propensity is that
benevolent being, for one that loves being in general will
have good-will to being in general. True virtue must, if
chiefly consist in love to God, for "he that has true love
existing in benevolence to being in general, and in benevo-
lent being, must necessarily have a supreme love to God
of benevolence and complacency. This theory he applies to
the theological dogmas that no one whose virtuous acts are
result of real conscious love to a personal God can possess a
righteousness, or he be in any other moral
utter depravity. As to the merits of the theory itself, it
is not helped by the form in which it is stated. Being in
benevolence without any act of love to a supreme
cause of love. The feeling which Edwards refers to
love, but save or reverence, and, moreover, necessarily a
bliss Properly stated, therefore, true virtue, according to him, is
just as a blind awe of being in general, and a love of compa-
to those who possess a blind awe of being in general—or
would be inconsistent with his definition of virtue as exist
God. In reality, as he makes virtue merely the second of
his love, his theory becomes identical with that of Leibniz, which
the names of Hume, Bentham, and Mill are closely
related, but it is similarly not necessarily expressed in a very awkward
because these are hampered by its derivation from certain theo-
principles, and its necessary connection with a theological be
Unlike Hume and Mill, he deduces his theory primarily from cer-
scolastic propositions regarding God's purpose in the creation
the world." He accepts the Scripture statement that God
himself as his own chief end, and he endeavours by scholastic resa-
looking to show the "reasonableness" of his doing so. He is, however,
unable to proceed a step in his argument without committing his
self to such pantheistic statements as that "God's existence, but
infinite, must be equivalent to universal existence," and that "the
inner and outer infinite are in reality identical," which
would imply universal existence. He is, therefore, obliged to con-
fess that "there is a degree of indistinctness and obscurity in the close
consideration of such subjects that I am at times inclined to fall back
against a principle of benevolent complacency," and,
that "this Implies the most perfect knowledge in these matters," although affirmative at the
same time that, in his endeavours "to discover what the voice of reason
is so far as it can go," he was successful in upholding an "elucidating"
meant by many.

The fame of Edwards is associated chiefly with his treatise On
the Freedom of the Will. His system is defined by which the "mind chooses anything" by "determining the
will," he means "causing that the act of the will or choice about
be thus and not otherwise." And, "with respect to the inquiry
What determines the will," he answers, "It is that motive
which as it stands in the view of the mind is the strongest." Leibniz
according to him, belongs not as the will itself, but to the per
and the liberty which any one possesses is merely liberty to act as
wills. Any other kind of liberty, he affirms, implies these sup-
positions:—(1) "a self-determining power in the will," (2) "indif-
ence,—that previous to the act of volition the mind is in a state
equilibrium;" and (3) "Contingence,—that events are not necessarily
connected with their causes. This supposition, an "revolution
of different forms denies the law of causality, are severally set:
be absurd. That Edwards demonstrates the position of
opponents to be utterly unwarranted is not left quite unam-
mitted; but he is unequally consistently overcome by his own theological position. Accordingly Erv
of the will, like Locke and Hume, is now held out, and those
who, in regard to the supreme power, are antagonists to
Edwards, theory differs in no respect from that of John Stuart Mill, et
that his statement of the doctrine of free will is a little confused that he gives a different account of the origin of our
knowledge of causality. He so far anticipated Hume as to recognize
the cause is often meant "an event coincident with which a cause
or event is so connected that it truly belongs to the reason wi
number of the authors shorter pieces are preserved in the
Paradise of Dainty Dames, first published in 1575, and
reprinted in the British Bibliographer, vol. ii.; the best
known are the lines on May, the Amantium Ira, and the
Commedation of Munc, which has the honour of furnishing
a stanza to Romeo and Juliet. The History of
Damosel and Disdaigne, ascribed to him in the third
edition of the Paradise. In his own day Edwards was
held in the highest estimation. "He united," says Warton,
"all those arts and accomplishments which minister to
popular pleasantry; he was the first fiddler, the most
fashionable somnambulist, the readiest rhymer, and the most
facetious mimic of the court."

Dott. of Brit and Aner Authors, the Shakespeare Soc. Papers, vol. n.
aed., Worn, English Dram. Literature, vol i.

EDWIN, or Edwine, king of Northumbria, was the
son of Eulla, king of Deira, and was born about 586. At
the death of Eulla, in 588, Ethelfred, king of Bernicia,
Eulla's brother-in-law, usurped the throne of Deira, and
united the two kingdoms Deira and Bernicia, under the
name of Northumbria. Edwin ultimately found shelter
with Rædwald of East Anglia, who let him, defeated and
slew Ethelfred near the river Idle, and enabled Edwin to
mount the Northumbrian throne. In 625 Edwin married
Ethelburga, daughter of Edbert, king of Kent. She had
been converted to Christianity, and, at her desire, Paulinus,
a Christian missionary, was allowed to enter Northumbria.
Not long after Paulinus's arrival, Eumer, an envoy of the
king of Wessex, made an attempt to assassinate Edwin, who
was only saved by Lulia, one of his thanes, throwing himself
between him and the assassin's weapon. The thane
was killed, and the sword passing through his body inflicted
also a dangerous wound on the king. The queen about the
same time was seized by the pangs of childbirth, and was
so alarmed on account of what had happened that she
and her infant were for a time in imminent danger.
Paulinus offered up prayers for their recovery, and Edwin
was so much impressed by the seeming answer to the
petition, that, though he did not at once adopt the Christian
faith, he permitted the infant and twelve of his household
to be baptized. He also declared to Paulinus that if he
should succeed in overthrowing the West Saxons, against
whom he had determined to make war, he would himself
become a Christian, and receive the rite of baptism. After
his victorious return he renounced his heathen gods, but
it required all Paulinus's powers of persuasion to get him
finally to adopt Christianity, and to give it his sanction as
the religion of Northumbria. Ultimately, however, he
convened a council of his nobles to ask their advice, and
when they unanimously declared for the new religion,
Cuth, the high priest, at once offered to destroy all the
heathen places of worship throughout the land. This
was done, and in 628 the Northumbrians flocked in crowds
to be baptized by Paulinus. While the introduction of
Christianity into Northumbria is the circumstance most
worthy of mention in Edwin's reign, it was also remarkable
in other respects. So strict was his administration of
justice, that it was said that "a woman with her babe
might walk scatheless from sea to sea in Edwin's day."
He was also the first real Bretwalda, although Eulla, his
father, first laid claim to the title. He compelled the
submission of the West Saxons, conquered Anglesea and
Man by his feet, and received tribute from all the king-
doms south of the Humber, with the exception of Kent.
To guard his northern dominion he erected the fortress of
Edinburgh or Ethelburg's. In 633 Penda, king of
Mercia, taking advantage of a reaction that was setting
in in favour of the old paganism, determined to resist Edwin's
authority and combining with Cadwallader, king of the
Western Britons, defeated and slew him at the battle of
Hestfield.

See Palgrave's History of the Anglo-Saxons, and Green's Short
History of the English People.

Edwy, Edwige, or Edwin, surnamed the Fair, an
Anglo-Saxon king, was the son of Edmund I., and suc-
cceeded his uncle, Edred, on the throne in 955, being then
from 16 to 18 years of age. With the following
Edwy, his younger brother Edgar reigning over
Mercia with the title of sub-king. On account of the re-
lation in which Edwy stood to Dunstan, abbot of Glaston-
bury, enraged at the affront thus put upon the church,
he more faithfully reproduced Rembrandt's peculiarities.

EECKHOUT, GERBRAND VAN DEN

Edwy died in 958.

EEL, a name applied more or less generally to all
species of Murwina, a family of soft-finned apodal fi
but more specially applicable to the species belonging
the sub-family Anguilina. The body throughout
the family of eels is greatly elongated and of snake-like fi
The ventral fins arewanting in all the species, while in
certain forms, as the Murena, the pectoral fins are ab-
sent. The skin is thick and soft, and is c
covered with a glutinous secretion which gives the eel
innumerable slipperiness. It is also sufficiently tough to en-
the skin as not to be apparent, while in such forms
the eel they are altogether wanting. The branchi-
openings are small, and lead into a sac, from which an-
deep is given off. The gills are thus exposed but slight-
ably to the drying influence of the atmosphere, and it is
rst to this, and to the slimy condition of the skin, that
e can exist for a considerable time out of water. Ac-
Dr Gunther, the Murewina comprise 26 genera and 23
species, inhabiting the seas and fresh waters of temper-
and tropical regions. Of these only the true eel, Anguilla,
habit fresh water, although most of the latter are likewise
marine.

Although abounding in almost every river, lake, and
estuary in Europe, little was known until recently of the
life-history of the fresh-water eels. With regard to the
origin Aristotle believed that they sprang from the mud
of the rivers, and in harbours where the water is
brackish. To reach these spawning grounds, eels migrate in
the autumn down the river channels, and at those times they

en in large numbers by various devices, such as the
ack" of the Thames, a wooden framework support-
baskets, the mouths of which are opposed to the
and which are so constructed that the fish when
nailed is unable to extricate itself. When there are
dles in the way of their getting to the sea, eels are known
pott their spawn in the beds of fresh-water streams,
t is still doubtful whether this may not also occur in
where the sea is quite accessible. Eels are peculiarly
ne to cold, and the fact that the temperature of the
flash waters of estuaries is always higher than that of
ixed salt or fresh water is an additional reason for
seaward migration on the approach of winter. In
erning this journey the darkest nights are chosen, the
ight being sufficient to stay their progress. During
old of winter they lose their appetite and become
ld, large numbers of them congregating together for the
of the additional warmth thus obtained, and burying
elves to a depth of 12 to 16 inches in places where
ceeding tide leaves them dry. In such places they
taken in large numbers by means of eel-spears. In
ershire, according to Yarrell, "the people know how
and the holes in the banks of the rivers in which eels
laid up, by the hour frost not lying over them as it
 elsewhere, and dig them out in heaps." In sprung, the
ation of the young eels up the rivers takes place, the
nts, according to some observers, performing a similar
ney. This migration takes place from February to May,
to the temperature, and some idea of the vast
umbers of young eels which annually pass up our rivers
y be formed from the fact that 1800 of them, each
out 3 inches long, have been observed to pass a given
int on the Thames in a single minute. This monster
asion of elvers, as these young eels are called, is known
the Thames as edelwars, and usually takes place about
beginning of May; and at these times, unfortunately,
ay be often caught in countless numbers in sieves,
special on the Severn, cartloads of them being sometimes
en for sale in the Exeter market. This upward migration,
ike that of autumn, is performed entirely by day, and
 it is carried through in spite of obstacles apparently
unapproachable to a fish. Eels have been known to
ade in steep ascents, 20 feet above the water, showing great skill
and ingenuity in availing themselves of whatever natural
ads the locality might afford. Couch tells of a remark-
able case in the neighbourhood of Inrato1, where the elvers
assed from one stream to another by means of a tree
ich stood between, and the branches of which dipped
nto the water of the lower. Ascending by these, the eels
dropped from the branches on the opposite side into the
upper stream. In some parts of Ireland the fishermen place
haybands on the rocky parts of the river-courses, in order
to facilitate the upward progress of the eels. The most
effectual obstacle, however, to their advance in either direc-
tion is found in a muddy or polluted state of the water, and
old eels, to get rid of such noisome conditions, have
been known to leave the water and travel for considerable
distances in search of purer surroundings. When confined
also in ponds they often show their migratory instinct by
leaving these in the night time, and attempting to make
their way to the nearest river or to the sea.

Like most animals that pass the winter in a torpid
condition, eels are exceedingly voracious during the summer
months, occasionally eating vegetables, but generally
preferring such animal food as young fishes, worms, and
the larvae of insects; they have also been known to devour
much larger creatures, as water-hens, rats, and snakes. Although their food is thus very various, it is essential that
it be fresh, eels at once rejecting whatever their keen sense
of smell detected. Eels were held in great esteem
by the Greeks and Romans, and enormous prices were
sometimes paid for them; by the Egyptians, on the other
hand, they were held in abhorrence. Their snake-like
appearance has had much to do with the prejudice enter-
ained by many people against eels, and to this may be
attributed the fact that in Scotland this valuable fish is
almost wholly rejected as an article of food. Their value
in this respect has, however, been recognized in England
from very early times, the taste for eels having probably
been acquired during the Roman occupation. The Vener-
able Bole states that England in his time was famous for
its salmon and eel fisheries, and Elly is said to have got its
name from the abundance of the eels in that fenny neigh-
bourhood. Eels are very largely consumed in London, the
greater proportion of these, numbering about 10 millions,
being brought alive annually from Holland in welled boats.
The greatest eel-breeding establishment in the world is that
at Comacchio on the Adriatic, where an immense swamp,
bounded and fed by two of the mouths of the river Po, 140
miles in circumference, has been utilized for this purpose.
The industry is very ancient, having yielded in the 16th
century an annual revenue to the Roman Pontiffs, in
whose territory it was, of £12,000. The eels are cooked
at Comacchio, and forwarded to the principal towns of
Italy.

The best known and most widely distributed fresh-water
species is the Sharp-nosed Eel (Anguilla vulgaris). It
occurs, according to Dr Gunther, in Europe to 64° 30' N.
at, in the Mediterranean region, and in North America,
but neither in the Danube, nor in the Black and Caspian
Seas. Like all other eels, it is a very slow-growing fish, but
attains a large size, measuring sometimes 5 feet in length, and weighing in such cases from 20 to 30 lb.
Few eels, however, weigh more than 6 lb. They are
believed to be long lived, one authentic instance being
known of an eel which was at least 31 years old. The
colour of the species is generally dark olive-green on the
upper surface, becoming lighter on the sides, and white
beneath; but the colour depends somewhat on the nature of the stream it inhabits, those obtained in pure water
being known as silver eels from the lightness of their colour, while those found in muddy rivers are darker.

The Conger (Conger vulgaris) is the only British species of
sea-eel. It differs from the true eels in having the upper
jaw projecting beyond the lower, and in the entire
absence of scales. It is abundant in all parts of the
British coasts, especially on rocky ground, and attains a
length of 10 feet, weighing in large examples over 100 lb.
The conger is exceedingly voracious, feeding on other
fishes, and not sparing even its own kind. Its jaws are
strong and well armed, and the capture of a large specimen
is not unattended with danger to the fisherman. Its tail
is exceedingly sensitive and prehensile, the conger being
able with this organ to grasp the gunwales of the boat,
and by a sudden contraction of the muscles to throw itself
overboard, a smart blow on the kail, however, is sufficient
to prevent the possibility of this occurrence. The conger
is peculiarly sensitive to cold, and during severe frosts it is
often taken floating helplessly on the surface of the sea.
Mr F. Buckland states that in 1855 thousands of congrers
were found floating upon the water; they could progress
readily in any direction on the surface, but could not
descend, and consequently fell an easy prey to the boat-
men. In this way, no less than 80 tons were captured.

"The action of the frost," he says, "caused the air in their
swimming bladders to expand so much that the ordinary
muscles could not expel it at will." The chief eel fisheries are on the south and west coasts of England, but
these are not nearly so productive now as they formerly
were. The flesh is not held in much esteem.
The Electric Eel (Gymnotus electricus) belongs to a different family of apodal fishes (Gymnotidae). In its bony, dentate, and oval fin is entirely wanting, and the anal fin is a long, forming a fringe from the throat to the extremity of the tail. It attains a length of 5 or 6 feet, and frequents the marshes of Brazil and the Guianas, where it is provided with terrific electrical organs by means of which it is a provided, and which extends along each side of the lower portion of the tail. When this natural battery is discharged in a favourable position, it is sufficiently powerful to kill the largest animal; and, according to the classic works of the time, to change the line of certain roads, owing to the number of horses that were annually killed in passing through the pools frequented by the gymnoti. These eels are eaten by the Indians, who, before attempting to capture them, seek to exhaust their electrical power by driving horses into the pools. By repeated discharges upon these, they gradually expend this marvellous force; after which, being defenceless, they become timid, and approach the edge for shelter, when they fall an easy prey to the harpoon of the Indian. It is only after long rest and abundance of food, that this fish is able to resume the use of its suble weapon. (v. c.)

Most of the monumental effigies of England, i.e., the effigies of deceased persons, became common in the eleventh century the idea appears, for the first time, to have been carried into effect that the figure of a deceased personage should be represented by effigy upon his monumental memorial. These earliest attempts at commemorative portraiture were executed in low relief upon coffin-lids of stone or purbeck marble, some portions of the designs for the most part being executed by means of incised lines, cut upon the raised figure. Gradually, with the increased size and the greater architectural dignity of monumental structures, effigies attained to a high rank as works of art; and, about the same period, similar figures also began to be engraved, either upon monumental slabs of stone or marble, or upon plates of metal, which were affixed to the surfaces of slabs that were laid in the pavement of churches. Engraved plates of this class, known as "Brasses," continued in favour until the era of the Reformation, and in our own times their use has been revived. It seems probable that the introduction and the prevalence of flat monumental memorials, in place of commemorative effigies in relief, were due, in the first instance, to the inconvenience and obstruction resulting from the increasing numbers of raised stones on the pavement of churches; whereas the comparatively small cost of engraving plates, their high artistic capabilities, and their durability combined to secure for them the popularity they unquestionably enjoyed. It will be kept in remembrance that, if considerably less numerous than contemporary incised slabs and engraven brasses, effigies sculptured in relief, and with some exceptions in full relief, continued for centuries to constitute the most important features in more than a few medieval monuments. In the 13th century, it must be added, their origin being apparently derived from the engravings or sculptures in mosaic cups, their ancient and disappearing result in the formation of a just estimate of their true character and their consequent worth in their capacity as authors of face-portraiture. In the original contract for the construction of the monument at Warwick to Richard Beauchamp, the fifth earl, who died in the year 1449, it is provided that an effigy of the deceased noble should be executed in gilt bronze, with all possible care, by the most skilful and experienced artists of the time; and the details of the ornament and the ornaments of the figure are specified with minute particularity and precision. It is remarkable, however, that the effigy itself is described only in general and decidedly indefinite terms—"an image of a man armed." There is no provision that the effigy should ever be "an image" of the earl; and much less is there a single word said as to its being such a "counterfeit representation" of the features and person of the living man, as the contemporaries of Shakespeare had learned to expect in what they would accept as true portraiture. The effigy, almost as perfect as when it left the sculptor's hands, still bears witness, as well to the conscientious care with which the conditions of the contract were fulfilled, as to the eminent ability of the artists employed. So complete is the representation of the armour, that this effigy might be considered actually to have been equipped in the earl's own favourite suit of the finest Milan steel. The cast of the figure also evidently was studied from what the earl had been when in life, and the countenance is sufficiently marked and endowed with the unmistakable attributs of personal character. Possibly such a resemblance may have been the highest aim in the image-making of the period, somewhat before the middle of the 16th century. Three-quarters of a century later, a decided step further in advance towards the requirement of fidelity in true portraiture is shown to have been taken, when, in his will (1519 A.D.), Henry VII. spoke of the effigies of himself and of his late queen, Elizabeth of York, to be executed for their monument, as "an image of our figure and another of her." The existing effigies in the Beauchamp chapel and in Henry VII.'s chapel, with the passages just quoted.
will of the Tudor king and from the contract by the executors of the Lancasterian earl, with
some difficulty illustrate the gradual development of this idea of true personal portraiture in monumental effigies, during the course of the 15th and at the con-
venient of the 16th century in England. A glance at the naturally first rests on the royal effigies still
used in this country, which commence in Gloucester Cathedral with King John. This earliest example of a
set of effigies of which the historical value has never been duly appreciated is rude as a work of art, and
there is on it the impress of such individuality as illustrates that the sculptor did his best to represent the
Singularity as achievements of the art of the
Ege, the effigies of Henry III., Queen Mairnmore of
and her ill-fated son Edward II., the two former in
Salisbury Cathedral, the last in Gloucester Cathedral; and
here fidelity also as portraits no doubt can be entertained.
In the manner, the effigies of Edward III. and his queen
is, and those of their grandson Richard II. and his
consort, Anne of Bohemia (all at Westminster), and of
her other grandson, the Lancasterian Henry, whose
father might have made his better right to Richard's throne, if
his second consort, Joan of Navarre, at Canterbury—
all speak for themselves that they are true portraits.
Next follow the effigies of Henry VII. and Elizabeth of
York, to be succeeded, and the royal series to be completed,
by the effigies of Queen Elizabeth and the hapless Mary
Stuart, all of them in Westminster Abbey. Very instruc-
tive would be a close comparison between the two last-
known works and the painted portraits of the rival queens,
specially in the case of Mary, whose pictures differ so
remarkably from one another.
As the 15th century advanced, the rank of the personage
represented and the character of the art that distinguishes
an effigy will go far to determine its portrait qualities.
Still later, when more exact face-portraiture had become a
recognized element, sculptors must be supposed to have
aimed at the production of such similitude as their art
would enable them to give to their works; and accordingly,
when we compare effigies with painted portraits of the same
personages, we find that they corroborate one another. The
prevalence of portraiture in the effigies of the 15th and
17th centuries, when their art generally underwent a
rapid decline, by no means raises all works of this class,
or indeed the majority of them, to the dignity of true
portraits; on the contrary, in these effigies, as in those of
earlier periods, it is the character of the art in each partic-
sular case that will go far to determine its merit, value,
and authority as a portrait. In judging of these
latter effigies, however, they must be estimated by the
standard of art of their own era; and, as a general rule, the
effigies that are the best as works of art in their own
class are the best as, and the most faithful in their
portraiture. The earlier effigies, evidently produced in the
great majority of instances without any express aim at
exact portraiture, as we now employ that expression, have
nevertheless strong claims upon our veneration. Often
their sculpture is very noble; and, even when they are
ruined works of art, they rarely fail to be a rough
granodur about them, as exhibited in the fine bold figure
of Fair Rosamond's son, Earl William of the Long Sword,
which repose in such dignified serenity in his own
and occasioned cathedral at Salisbury. These effigies may not bring us
closely to face with the more remote generations of
our ancestors, but they do place before us true images of
what the men and women of those generations were.
Observant students of monumental effigies assuredly
will not fail to appreciate the singular felicity with which the
medieval sculptors adjusted their compositions to the
recumbent position in which their "images" necessarily
had to be placed. Equally worthy of regard is the manner
in which not a few monumental effigies, and particularly
those of comparatively early date, are found to have
assumed an aspect neither living nor lifeless, and yet impres-
sively lifelike. The sound judgment of the sculptor was
probably exercised in their exclusion, almost without an exception, the
more extravagant fashions in the costume of their era from
their monumental sculpture, and introducing only the
simpler but not less characteristic styles of dress and
appointments. In all representations of monumental effigies,
it must be kept in remembrance that they represent recumbent figures, and that the accessories of the effigies
themselves have been adjusted to that position. With rare
exceptions, when they appear resting on one side, these
effigies lie on their backs, and as a general rule (except in
the case of episocal figures represented in the act of
benediction, or of princes and warriors who sometimes hold
a sceptre or a sword) their hands are uplifted and composed
as in supplication. The crossed-legged attitude of numer-
ous armed effigies of the era of mail-armour has been
suspended to imply the personages so represented to have been
crusaders or Knights of the Temple; but in either case the
supposition is unfounded, and inconsistent with unquestionable facts. Much beautiful feeling is conveyed by figures
of many armed angels being introduced as in the act of sup-
porting and smoothing the pillows or cushions that are
placed, in very many instances to give support to the heads of
the recumbent effigies. The animals at the feet of these
effigies, which frequently have an heraldic significance,
enabled the sculptors, with equal propriety and effectiveness,
to overcome one of the special difficulties inseparable from
the recumbent position. In conclusion, it remains only to
remark upon the masterly treatment of outline composition
which so honourably distinguishes the earlier examples of
the engraved effigies in monumental brasses.

Egbert, or Egberht, king of the West Saxons, was
born about 775, and laid claim to the throne in 786, but
Brihtwic was elected, and he was compelled to take refuge
with Offa, king of Mercia. Although Offa refused to
surrender him when requested by Brihtwic, he declined to
honor further protection. Egbert thereupon fled to
France, and took up his residence at the court of
Charlemagne; and it is doubtless to the training he
received from that great general and statesman that the
success of his reign in Wessex is in a large measure to be
traced. When Brihtwic was poisoned by his queen
Edburga in 800, Egbert was recalled and ascended the
West Saxon throne. From his reign may be dated the
supremacy of the West Saxon kings in England. In 823
he defeated Beornwulf, king of Mercia, at Elendun
(near Wilton); and in the same year he united Kent, Essex,
and Sussex to his crown, and compelled East Anglia
to acknowledge him as its over-lord. In 827 he compelled
the submission of Mercia, and leading an army into
Northumbria received its submission without trial of
battle. In 828 he conquered Wales, and thus the isle of
Britain, with the exception of the Picts, the Scots, and the
Strathclyde Welsh, acknowledged a West Saxon king as its
over-lord. During the last period of his reign his kingdom
was subjected to repeated attacks by the Danes. In 832
they ravaged Shropshire, and in 833 defeated Egbert at Cudham
(thought by some to be Charming, in Devon), but in 835
he gained a great victory over a united force of Danes and
Wclsh at Hengestdunesh in Cornwall. He died in 836.

Ege, Hans (1656-1758), the first missionary of
Greenland, was born in the workshop of Sebastian
on the 31st January 1656. In his 22d year he became
pastor at Waagen, in the bishopric of Drontheim, but the
study of the chronicles of the northmen having awakened in him the desire to visit the colony of northmen in Greenland, and to convert them to Christianity, he resigned his charge in 1717; and having, after great difficulty, obtained the sanction and help of the Danish Government to his enterprise, he set sail with three ships from Bergen on the 3d May 1721, accompanied by his wife and children. He landed on the west coast of Greenland on the 3d July, but found to his dismay that the northmen were entirely landed on the west land in establishing superseded interest, and endure for some years great gradual in converting many of them to Christanity, and he soon gained the made. He published a Greenland-Danish-Latin Dictionary (1750), Greenland Grammar (1760), and Greenland Catechism (1766). In 1766 he completed the translation, begun by his father, of the New Testament into the American; in 1787 he translated Thomas Kempis. In 1789 he translated Thomas a Kempis. In 1789 he published a journal of his life in Greenland.

EGER, the chief town of a circle in the kingdom of Bohemia, is situated on the river Eger, and lies at the foot of one of the spurs of the Fichtelgebirge. It possesses an upper gymnasion and a real-school. In the townhouse, which at that time was the burgomaster's house, Wallenstein was murdered, 28th February 1634. His sword and writing table are exhibited in the town. Among the industries of Eger are the manufacture of cloth of various sorts, hats, and shoes. Population in 1869, 13,390.

In 1778, he in the 12th century, the Egermap was formed as an oiled possession of the counts of Vohburg; but they were added to the imperial dominions on the marriage of Adelheid of Vohburg with Frederick I. After being repeatedly transferred from the one power to the other, according to the preponderance of Bohemia or the empire, the town and territory were finally incorporated with Bohemia in 1850, after the Bohemian king became the emperor Charles IV. Several imperial privileges, however, continued to be enjoyed by the town till 1849. It suffered severely during the Thirty Years' War, during the Swedish invasion in 1631 and 1647, and in the War of the Austrian Succession in 1742. (See Graber, Das Königreich auf Eger, 1865; Dvorak, Aulere Geschichte der tschechischen Eger und des bischöflichen Egerland, 1874.)

EGG, the name given to the body formed in the female reproductive organs, which, when impregnated by the male element, gives origin to the young of animals. Although differing widely among themselves in form and structure, the eggs of all animals are found to consist of the same essential parts, viz., the germ cell, the yolk, and the yolk membrane. The chief difference between them consists in the relative quantity of the yolk element present, this apparently depending on the degree of development which the young attain before leaving the egg. Thus birds, which leave the shell in a highly developed state, have in their eggs a large quantity of yolk, besides the albumen or "white," which is added to the egg before it receives its outer calcaceous covering and which, along with the yolk, serves as a storehouse of food for the young chick during the process of incubation. In insects, on the other hand, which leave the egg in the immature condition of larve, the yolk is comparatively small, as it is also in mammals, whose young are born in a comparatively undeveloped condition. The process of incubation, which is continued only until the egg is hatched outside; a few are ovo-ooviviparous, the eggs being retained in the oviduct until the young are ready to leave; while mammals are viviparous, the young, after leaving the egg, attaining considerable development before birth, in the womb of the female. In oviparous animals, the egg, within certain limits, is proportional in size to the adult form to which it gives origin; the larger the bird, for example, the larger, as a rule, is the egg. This, however, is not without exceptions; thus the eggs of the guillemot is as large as that of the eagle, and ten times larger than that of the raven, although guillemot and raven are of nearly equal size.

Owing to the fluid nature of the contents of eggs, they are generally roundish in form, although in this respect they also offer considerable variety; thus the eggs of owls and of turtles are nearly spherical, those of ducks, crocodiles, and snakes oval, and those of most sea-fowl pear-shaped. The external covering is generally more or less smooth, thin, or thick, in the eggs of birds, but in the case of insects it exhibits the most varied markings, being covered with spinous tubercles, and pits, often symmetrically arranged. Considerable diversity also exists in the composition of the outer covering of the egg in oviparous animals; in snakes and lizards it consists of a parchment-like membrane not unlike the inner coating of a hen's egg; in birds, turtles, and the majority of mammals, it is a semi-transparent, cartilaginous or albuminous covering which is secreted by the viscous glands, and in the higher mammals, such as man, cartilaginous fishes, as sharks and rays, the egg in passing through the oviduct is imbedded in a four-sided horny case, from the corners of which tendrils are given off, by which the egg-capsule is moored to floating sea-weed. These, after the escape of the young fish, are often cast upon the shore, where they are familiarly known as "mermaid's purses." The external covering of the eggs of oseous fishes, as salmon and trout, is exceedingly tough and elastic, "rebonding," says Mr Frank Buckland, "from the floor like an india-rubber ball;" and this no doubt prevents them from being crushed in the gravelly beds of the running streams in which they are deposited, and are separated from fresh water by a tough layer of albuminous substance, which expands in water into a transparent jelly. The eggs of the frog occur in great masses, piled together like miniature cannon balls, while those of the toad are connected together so as to resemble strings of beads. Among many molluscous animals the eggs are provided with an additional covering or nidus, consisting of a leathery pouch or cup, containing a large number of eggs. These capsules are either attached singly, by little stalks, to the rocks as in the common purpura (Purpura lapillus), or are extruded in a compound mass as in the whelk (Buscarius undatum). Those of the latter were named by Ellis "sea wash balls," from being used by the sailors instead of soap to wash their hands, and are common objects on the sea-shore. The greatest variety exists in the number of eggs produced by different animals, and even among forms allied to each other. Thus the common snail produces only from tens of thousands. Among insects, the white ant is pre-eminentin proflicity, the queen being said to lay about sixty eggs in a minute, or upwards of 80,000 in a day, and as this probably continues for two years, it is estimated that the total number of her eggs amounts to fifty millions. Among mollusks the spawn or

EGG.—EGG.

EGG, AUGUSTUS LEOPOLD (1816–1863), a painter, was born on 24 May 1816, in Piccadilly, London, where his father carried on business as a gun-maker. He had some schooling at Eton, and was not at first intended for the artistic profession; but, developing a faculty in this line, he entered in 1834 the drawing class of Mr. Sass, and in 1835 the school of the Royal Academy. His first exhibited picture appeared in 1837 at the Suffolk Street Gallery. In 1838 he began exhibiting in the Academy, his subject being a Spanish girl; altogether he sent twenty-seven works to this institution. In 1848 he became an associate, and in 1860 a full member, of the Academy. In 1857 he took a leading part in selecting and arranging the modern paintings in the Art-Treasures Exhibition in Manchester. His constitution being naturally frail, he went in 1853, with Dickens and Wilkie Collins, to Italy for a short trip, and in 1863 he visited Algeria. Here he benefited so far as his chronic lung-disease was concerned; but, riding out one day exposed to a cold wind, he caught an attack of asthma, which cut him off on 29th March 1863, at Alger, near which city his remains were buried.

Egg was a gifted and well-trained painter of genre, chiefly in the way of historical anecdote, or of compositions from the poets and novelists. As years progressed, he developed in seriousness of subject matter and of treatment, and at the time of his death he might be ranked among our best painters in his particular class—clever, skilled, and observant—although he had not any marked originality of point of view or of style. Among his principal pictures may be mentioned: 1839, the Introduction of Sir Pierce Shafton and Halbert Glendinning (from Scott's Monastery); 1846, Buckingham Rebuffed; 1848, Queen Elizabeth discovers she is no longer young; 1850, Peter the Great sees Catharine for the first time; 1854, Charles I raising the Standard at Nottingham (a study); 1855, the Life and Death of Buckingham; 1857 and 1858, two subjects from Thackeray's Esmond; 1858, Past and Present, a triple picture of a faithless wife; 1859, the Night before Naseby; 1860, his last exhibited work, the Dinner Scene from The Tempest of the Shrew. The National Gallery contains one of his earliest pictures, Patience entertaining two Ladies, from the Duble Boutez, it was painted in 1844.

Egg was rather below the middle height, with dark hair and a handsome well-formed face; the head of Peter the Great (in the picture the Winter and Catharine, who was regarded as his best work, along with the Life and Death of Buckingham) was studied, but of course considerably modified, from his own countenance. He was manly, kind-hearted, pleasant, and very genial and serviceable among brother-artists; social and companionable, but holding mainly aloof from fashionable circles. As an actor he had uncommon talent. He appeared among Dickens's company of amateurs, in 1852 in Lord Lytton's comedy Not so Bad as we Seem, and afterwards in Wilkie Collins's Frozen Deep, playing the humorous part of Job Want.

EGNIARD is best known as the biographer of Charlemagne. His name is variously spelled in manuscripts. Einhardus, Einhartus, Heinhardus, Heinhardus, are the earliest forms. In the 10th century it was altered into Aguanus, and out of this form arose Eggnardus and Egginhardus. The French and English languages have adopted this latter form; but it is unquestionably wrong, and the weight of authority is for Einhardus or Einhartus. The circumstances of his life are involved in considerable obscurity, owing partly to the want of scrupulosity or indefiniteness of our authorities. According to the statement of Walfridus Strabo, a contemporary, he was born in the district which is watered by the river Maine in the modern duchy of Hesse.
Darmstadt. Teulet has disputed the genuineness of the document in which the statement is contained, because "it exists only in one manuscript of the 15th century, and it contains an evident anachronism." The anachronism, however, is a mistake on the part of Teulet, for he understands by "pedagogium Sancti Bonifacii" a school taught by St Boniface, whereas it plainly means a school in the monastery of St Boniface, as Jaffe takes it. The date of his birth can only be conjectured, but it must be somewhere about the year 770 A.D. His parents were noble, and probably their names were Elnhardt and Engilfrit. He was educated at the monastery of Fulda. There is documentary evidence that he was resident in that place in the years 788 and 791. Owing to his intelligence and ability he was transferred from the monastery by its abbot Baugolus to the palace, where he became intimate with the emperor and his family, and received commissions of great trust and importance. His removal to the palace took place not later than 796.

He was entrusted by the emperor with the charge of public buildings. He thus became one of the imperial ministers, and resided with the emperor at Aix-la-Chapelle. In reference to his artistic skill he received the Scripture name of Beated (Exod. xxxi. 24, and xxxv, 30), according to a fashion then prevalent of giving ancient names to contemporaries. Some suppose that he constructed the basilica at Aix-la-Chapelle and the other buildings mentioned in chapter xviii. of his Life of Charlemagne, but there is no express statement to that effect. The emperor employed him in 806 as legate to Rome to obtain the Pope's signature to a will which he had made in regard to the division of his empire. Hence the inference has been drawn that he was the emperor's secretary; but no contemporary ascribes this office to him.

It was owing to Eginhard's influence that in 813 Charlemagne made his son Louis partner in the empire. Louis, on becoming sole emperor, proved grateful to Eginhard, retained him in the office of head of public works, made him tutor to his son Lothair in 817, and showed him every mark of favor.

Eginhard married Imma, a noble lady, a sister of Bernharus, who was bishop of Worms and abbot of the monastery of Wiesenbug. Later tradition converted Imma into the daughter of Charlemagne, and invented a romantic story in regard to the marriage of Eginhard and Imma. It is doubtful whether he had any offspring. Eginhard addresses a letter to a person called Vusin, whom he styles "filii," "mi nato." These expressions and the tenderness of the language almost compel the belief that Vusin was his son; but as Vusin is never mentioned in several deeds in which his interests would have been concerned, and in which the names of Eginhard and Imma appear, some have supposed that Vusin was merely a spiritual son.

On January 11, 815, Louis bestowed on Eginhard and his wife the domains of Michelstadt and Mulheim in the Odenwald on the Maine. In the document conveying this property to him he is simply called Elnhardt, but in a document of June 2, 815, he is called abbot. In becoming abbot he did not dismiss his wife. After the period we find him at the head of several monasteries — Blanduny of Ghent, Fontenelle in the diocese of Rouen, St Bavon of Ghent, St Servais of Maastricht, and St Cloud (but not the St Cloud near Paris), and he had also charge of the church of St John the Baptist at Tavis.

Eginhard began to grow tired of the intrigues and troubles of court life, and in 830 finally withdrew to Mulheim, which he named Seligenstadt, where he had erected a church to which he had transported the relics of St Marcellinus and St Peter. His wife helped him in all his efforts, and her death in 836 caused him bitter grief. The emperor Louis visited him in his retreat the same year, probably to console him, but Eginhard did not long survive his wife, for he died March 14, 840.

Eginhard was a man of culture. He had reaped the benefits of the revival of education brought about by Charlemagne, and was on intimate terms with Alcuin. He was well versed in Latin literature, and knew Greek. He was very small in body, a feature on which Alcuin wrote an epigram. His most famous work is his Vita Caroli Magni, written in imitation of the Lives of Suetonius, is the most reliable account of Charlemagne that we have, and a work of some artistic merit. It was written soon after the death of the great emperor. It was very popular in the Middle Ages. Pertz collated upwards of sixty MSS. for his edition.

The other works of Eginhard are — (1) Annals Francorum, extending from 741 A.D. to 829 A.D.; some doubt their authenticity, without good reason; (2) Vita Notabilis, handed down only in MSS., not at Laon and of considerable importance for the history of the times; (3) Historia Translationis Beatorum Christi Martyrum Marcellini et Patii, written in 830, and giving a curious narrative of how the bones of the martyrs were stolen and conveyed to Seligenstadt, and what miracles they wrought there; (4) This is added to the same subject. A treatise written by him, De Adoranda Cruce, has not come down to us.

The literature on Eginhard is very extensive, almost all who deal with Charlemagne, early German literature, and early French literature treating of him. The fullest and most accurate accounts are given by Teulet and Jaffe in their editions.

The modern editions of Eginhard's works are by Pertz in vol. i. and of his Monumenta Germaniae Historica, Hanover, 1856; 1859; Teulet, Elnhardt omnia que extant Opera, Paris, 1840; Migne, Patrologia Latina, tom. 104, Paris, 1866 (the Life of Charlemagne is in vol. 97), and Philip Jaffe in vol. iv. of his Bibliotheca Hterarum Germanicarum, Berlin, 1857. Teulet's is the most perfect edition, and he describes special praise in connection with the letters. Pertz and Jaffe published the Life of Charlemagne separately for the use of scholars. Teulet gives a full account of all previous editions, of the MSS., and of translations. Some of the other editions contain bibliographical references. A translation of the Life of Charlemagne has appeared in English by W. Glazier, London, 1877 (J. D.)

EGLANTINE (E. Frisian, epelltore; French, aglantier), a name for the sweet-brier, Rosa rubiginosa, and for R. lutea, another species of Lindley's tribe of Rosa Rubiginosae, and apparently the R. Eglanteria of Linnaeus. The signification of the word seems to be thorn-tree or thornbush, the first two syllables probably representing the Anglo-Saxon egle, egle, a prick or thorn, while the termination is the Dutch tera, (ara, a tree (see Wedgwood, Dict. Eng. Etymology). Eglantine is frequently alluded to in the writings of English poets, from Chaucer downwards. Milton, in L'Allegro, l. 48, is thought by the term "twisted eglantine" to denote the honeysuckle.

as the saviour of Flanders from devastation by the French. He was nominated by Philip stadtholder of the provinces of Flanders and Artois. At the conclusion of the war by the treaty of Cateau Cambresis, Egmont was one of the four hostages selected by the king of France as pledges for its execution. As stadtholder he now showed some sympathy with the popular discontent excited by the Spanish Government, and particularly by Cardinal Granvelle, minister to the regent Margaret. As a member of the council of state he joined the prince of Orange in a vigorous protest addressed to Philip (1561) against the proceedings of the minister; and two years later he again protested in conjunction with the princes of Orange and Count Horn. He was invited by Philip to go to Spain to confer with him on the subject of the remonstrance, but he declined. Egmont, however, who was a strict Catholic, afterwards spoke in less hostile terms of the minister; and, at the same time that he was currying the favour of the middle classes, he was becoming more a favourite at the court of the regent. In January 1563 he accepted a special mission to Spain to make known to Philip some extent the state of affairs in the Netherlands and the demands of the people. At Madrid the king gave him an ostentatious cordial reception, and all thecourtiers vied with each other in lavishing professions of respect upon him. But earnest discussion of the real object of the mission was evaded by the king, and Egmont had to return to the Netherlands loaded only with fine words of flattery and promise. At the very same time instructions were sent to the regent to abate nothing of the severity of persecution and the Inquisition was re-established. Egmont was indignant, and the people were in a state of frenzied excitement. In 1566 a confederation of the nobles (Les Gueux) was formed, the document constituting it being known as the Compromise. Egmont then withdrew to his government of Flanders, and showed himself, after some vacillation, an unscrupulous supporter of the Spaniards and fierce persecutor of heretics. In the summer of 1567 the duke of Alva with an army of veterans arrived in the Netherlands, to supersede the regent Margaret, and to crush with the strong hand the popular opposition. One of his first acts was the arrest of Count Egmont and Horn, who were imprisoned at Ghent. A sham process was begun against them, and after some months they were removed to Brussels, where sentence was pronounced by Alva himself on the 6th June 1568. Egmont was declared guilty of high treason and condemned to death. It was in vain that the most earnest intercessions had been made in his behalf by the emperor Maximilian, the order of the Golden Fleece, the states of Brabant, the electors of the empire, and the regent herself. Van, too, was the pathetic pleading of Egmont's wife, who with her eleven children was reduced to want, and had taken refuge in a convent. Egmont was beheaded at Brussels the day after the sentence was pronounced, June 5. He met his end with calm resignation; and in the storm of terror and exasperation to which this tragedy gave rise Egmont's sufferings were forgotten, and he and his fellow victim to Spanish tyranny were glorified in the popular imagination as martyrs of Flemish freedom. This memorable episode proved to be the prelude to the famous revolt of the Netherlands, the issue of which was independence. Goethe's poem of 1856 was founded on this event. In 1865 a monument to Counts Egmont and Horn, by Friaen, was erected at Brussels.

Full details may be found in Berichts Geschicht des Ortes Egmont (1810); Clonet's Histoire du Comte d'Egmont (1823); Françoix's History of Philip the Second; Jontest's History of the Dutch Republic (1849); and Juste's La Compagnie d'Egmont et de Comte d'Hornes (1862).

EGRET. See Hirond.
EGYPT

Plate VI. Egypt is a country at the northeasterly extremity of Africa, bounded on the N. by the Mediterranean Sea, on the E. by Palestine, Arabia, and the Red Sea, and on the W. by the Great Desert.

The name of Egypt in hieroglyphics is Kem, which becomes Ënëm in Coptic, or Ënëm (Saabic), Kheshekh (Basboun), and Kh Phillips (Memphitic), with unimportant variants. The sense is "the black (land)," Egypt being so called from the blackness of its cultivable soil.

In Hebrew Egypt is called Mizraim, Ënëm, a dual, sometimes used as a singular. It describes the country with reference to its two great natural divisions, Upper Egypt and Lower Egypt, or the Delta. In the prophecies Mazor, "the land of Mazor," occurs as the singular form, and means Lower Egypt, Pathroes being used for Upper Egypt. Thus Mizraim may be compared to the two Sicilies, though sometimes we find Mizraim for the lower country where we should expect Mazor. (Geour, Thes. s. s. Mizraim.) The meaning of Mazor is probably the "fortified," rather than the "border," referring to the natural strength of the country.

The Greek Ägyóptos first occurs in the Homeric writings. In the Odyssey it is the name of the Nile (masculine) as well as of the country (feminine). Afterwards it is not used for the river. No satisfactory Egyptian or Semitic origin has been proposed for it. The probable origin is the Sanskrit root gyp, "to guard," whence may have been formed Äyptos, "guarded about," a similar sense to Mazor. The Hebrew Mazor is preserved in the Arabic Misr, pronounced Misr in the vulgar dialect of Egypt.

1 Cf. Plat. De India et Orient. cap. 33. Dr Brugsch objects to the idea, that Kem may be connected with the biblical patriarchal name Ham, (forming part of poetic names of Egypt in the Psalms — "the land of Ham," cv. 63, 77, cv. 22; "the sons of Ham," Is. viii. 61), on the ground that it is philologically difficult to connect the Egyptian Kem with Ham (Geor. Inscr., i. p. 74, note 8). This objection would be valid were the case one of a Semitic word transcribed in ancient Egyptian; it is not so where we have a root which is common, as this may be, to both (cf. Bunsen's Egypt's Place, t. 751, 758). The meaning of the Hebrew root Kph is "hot, warm." The Arabic root 75 signifies "it became hot," and describes blackness as a result of heat; and the word 75 black mud also occurs.

2 The use of Mizraim as the proper name of an individual appears to be as early as the time of Rameses II. Mizraim occurs as the name of a hill, the brother of the king (Brugsch, Geor. Inscr., ii. 35, pl. xvii. 77). The Hebrew dual form is similarly transcribed in Misktrim, Masaam, Masaam (n. 61, pl. xxiv. 29), a word not actually dual, and the Semitic dual also in Nebamim, the Hebrew Naharim (n. pl. ix. 333).

3 Pathros may take its name from the Pathyros Nome, so called from its metropolis, P-hat-bar (Brugsch, Geor. Inscr., i. 185, 189, pl. xxvi. 839). As this nome contained Thebes, it might have a significance like Thebais. De Rouge prefers p-to-re, "the country of the south," or Upper Egypt. (See Francius Dastastus, Mem. de l'Inst., xxv. 931.)

4 Dr Brugsch has conjecturally identified Äyptos with Hâkephath, the sacred name of Memphis, from which is the westernmost branch of the Nile, the Canopic, with its two mouths, the Canopic and the Red Butane, those best known to the early Greeks, seem to have been called (Geor. Inscr., i. 83)."}

EGYPT

It occurs in the Koran as the name of Egypt (iii. 50), but has been applied to the country and to its chief capital since the Arab conquest, El-Fustâ, now called Mâr â'Atsah, or Old Misr, and El-Kâhir, the Cairo of the Europeans.

By the Greeks and Roman Egyptians was usually assigned to Asia, though some gave it to Libya, or Africa. This difference was owing to the adoption of the Nile as the division of the two continents, which would naturally have given half of the country to each continent.

In ancient times Egypt was the country watered by the Nile north of the First Cataract, the deserts on either side being assigned to Arabia and Libya. The Egyptian name "the black land," is only applicable to the cultivable lands. The Mur of the Arabs is distinctly restricted to the same territory, the adjoining deserts being called the deserts of Egypt. Physically, ethnographically, and politically, the two tracts are markedly different, but it is now usual to treat them as a single country.

PHYSICAL GEOGRAPHY, PRODUCTIONS, AND INHABITANTS.

The political advantages of Egypt, in situation, natural strength, and resources, can hardly be overrated. It has the very route of the trade between Europe and Asia, and between Africa and the other two continents. It is the gate of Africa, and the fort which commands the way from Europe to the East Indies. The natural ports on the Red Sea and the Mediterranean, selected and improved by the wisdom of Alexander and the Ptolemies, whose enterprises have been eclipsed by those of M. de Lesses in our own days, have always been enough for its commerce, which the great inland water-way of the Nile has greatly aided. The inhabited country, guarded by deserts and intersected in Lower Egypt by branches of the Nile and canals, in Upper Egypt closely hemmed in by the mountains on either side, is difficult to reach and to traverse; at the same time its extreme fertility makes it independent of supplies from other lands, and thus easier to defend. The ancient wealth and power of Egypt should occasion us no wonder, nor even that the country still prospers in spite of centuries of Turkish misrule.

"The extent of the cultivated land in Egypt [Mr. Lane calculates] to be equal to rather more than one square degree and a half; in other words, 5500 square geographical miles. This is less than half the extent of the land which is comprised within the confines of the desert; for many parts within the limits of the cultivable land are too high to be inundated, and consequently are not cultivated, and other parts, particularly in Lower Egypt, are occupied by lakes, or marshes, or drifted sand. Allowance also must be made for the space which is occupied by towns and villages, the river, canals, &c. Lower Egypt comprises about the same extent of cultivated land as the whole of Upper Egypt." Since the date when this was written...
1844, the extent of cultivated land has increased. This has been chiefly due to works of irrigation in Lower Egypt, the increased cultivation of cotton, and the greater facility of transport. The increase cannot, however, be very large.

Diamm --The ancient like the modern Egyptians followed the natural division of the country into two tracts, the valley of Upper Egypt and the plain of Lower Egypt. The names in hieroglyphics are to-re, the "south land" (compared, with the article prefixed, to-re, to Pathros by M. de Rouge), and to-mer, the "north land." The two were divided by the southern boundaries of the highest plains of Lower Egypt, the Memphite and Helopolis, and thus the political boundary was somewhat south of the position where the valley extends into the plain.

The most southern nome of Upper Egypt was called that of Naba, and began at Sais. The Greek and Roman division excludes the Menophite Nome from Lower Egypt.

It is not known at what date Egypt was first divided into the provinces called Names. They are noticed in inscriptions of Dynasty IV. (Brugsch, Geogr. Inschr., i, 93), and from that time onward the name of Hesperia, the "two names," fifth king of Dynasty I, Manetho's Unaphedus. The hieroglyphic name is hpsr. In later inscriptions the term (psr) occurs, which is also the demotic form, and the origin of the Coptic (ID, i, 94, 98).

The number of nomes is somewhat different in the various ancient Egyptian lists, all of which, except fragments, are of the Graeco-Roman age. Probably the number varied at different times. Dr. Brugsch conjectures the true number to be forty-two, considering the forty-two judges of the dead (Rev. xiv, 19) as called from the chief towns of the kingdom to a great tribunal (Geogr. Inschr., i, 99), which he thinks represents the earthly court described by Diodorus Siculus (v, 75) (Geogr. Inschr., i, 124).

There was a double system of names for the nomes, the serial, usual in hieroglyphics, and the vulgar, taken from the capitals, and preserved in Greek in transcription or translation. In consequence of this double system the identification of the hieroglyphic names with those of the Greeks and Romans is not always certain. This is the case in Lower Egypt, where the form of the country makes it difficult for the exact geographical relation intended by any order. On account of this difficulty, and because the hieroglyphic names are of inferior importance in the geography of Egypt, they are not here given. (See Brugsch, Geogr. Inschr., i, 93, seq.)

By the Greeks and Romans Egypt was divided into the Delta or lower country, and the Thebais or upper country. The third division, the so-called Middle Egypt, first occurs in Ptolemy as the Seven Nomes, Ευκίτου, or Ἐρυθροῦ.

There is another name of the same as the foregoing, Ἐρυθροῦ Πολιτικός, the political division of Egypt, as extended by the Greeks and Romans. This is the same as the Menophite Nome from Lower Egypt to the Thebais, and the Thebais, as the divisions to which nomes thus designated are known to belong.

Διασώστικα: Μικρή χάρασσα του ερυθρού πολιτικού, που ακολουθεί την ερυθρή πόλη γύρω από την περιοχή της Καταλύσης, έχει δύο βασικές επιτάξεις: την δυτική και την εαυτική. Η περιοχή της Δυτικής Ελληνικής και της Επούλων είναι γνωστή από την αρχαιότητα, καθώς και η τεχνική της ερυθρής πόλης, που χρησιμοποιείται για την κατασκευή και την διασκεδαστική τεχνοτροπία.
The Syrian 'Ap'asa, 1. PharbllBthitea, Stlbennytal. territory of the Heptanomis does not appear in the hieroglyphic laws, because Sakel, the crocodile-headed divinity there worshipped was, at least in later times, displaced in most parts of Egypt (Brough, Inst. 2 ed., 104, 105).

The Notitia Dignitatum, composed under Theodosius II, A.D. 408-450, gives a new a division of Egypt into four provinces—Egyptus, Augustanum, Arcadia, and Thebaia. Roughly the first comprised all Lower Egypt except the part east of the Delta, which was assigned to the second, and Arcadia appears to have succeeded the Heptanomus (Parthey, Elämendde, 518, taf. vii.).

About the time of Justinian I this division is found to be further developed, according to the statements of Hecataeus. Egypt contained six eparchies:—1. Egypt Proper, Apis-sacred, the west of Lower Egypt to the Sobectytic branch of the Nile; 2. The First Augusta, Apis-sacred a, the north-eastern part of Lower Egypt to the Syrian border; 3. The Second Augusta, Apis-sacred b, the territory southward of the First Augusta; 4. Arcadia, 'Arsach, the earlier Heptanomus; 5. The Nearer Thebaia, Θηβαία η ευχαριστή, extending to Panos, or Panopolis, and including the Great Oasis. 6. The Upper Thebaia, Θηβαία ς ευχαριστή, as far as Philae. The division into nomes had evidently been almost effaced at this time (I. 520, taf. 105).

The Copts preserved the oldest division of the country, and called Lower Egypt, the Northern Region, Α.Β.Σ.Τ. (Mem.), Α.Β.Ρ.Μ. (Sah.), Upper Egypt, the Southern Region, Α.Β.Ν.Θ. (Mem.), Α.Β.Ν.Θ. (Sah.). The names of the nomes were also known to them, and are given by Champollion in L'Egypte sous les Pharaons.

Like the Copts, the Arabs generally know of but two divisions, the names of which are such as the people of the desert would naturally give to the country watered by the Nile. Lower Egypt is called El-Reef, the cultivated, or fertile, and Upper Egypt, Elwaas, the happy, or fortunate.

Under the Memlook sultans of the Bâhârâ dynasty, as we learn from the list appended to De Saify's Abât-Allah, referring to A.D. 715 (A.D. 1315-6), the provinces of Egypt were less numerous than the ancient names. They are for Lower Egypt—the territory of Cairo and the provinces of Kalyoob, the Sharkeyeh, the Dakahlia, the Ed-Dimyât, the scarce, the Kalyoob, and that of Al-Geezeh. The Middle Provinces, E. Akaleel el-Wastaneeyeh, were that of Atfeh, the Feyoom, and those of Bannee-Sweyf or Behnese, and of El-Minya or Ashmooney.2 The Southern Provinces, El Akaleel el-Kileeyeh, were those of Asyoot, Girgh, and Kond.

There is no doubt that these provinces sometimes correspond to the ancient nomes, though generally composed of territories of more than one. (Cf. Jomard in Descr. d'Egypte, 2d ed. ix. 594, 595.) By Mehemet Ali a new division was formed into districts governed by a mukarrir of which Lower Egypt, including a small portion of the Middle Provinces, contained four, and the rest of Egypt three. At the present time Egypt is divided into fifteen provinces, each governed by a mukarrir.

### III. UPPER EGYPT

—Edmond L'Egypck, 209, 270.

It will be readily understood that much confusion prevails as to the divisions of the country, much especially at times when an arbitrary administrative division has been used side by side with a popular one, depending upon what nature and artificial aids, such as canals and dikes, have been done to map out the country. The general appearance of Egypt is remarkably uniform. The Delta is a level plain richly cultivated, and varied along by the lofty dark-brown mounds of ancient cities, and the villages in groves of palm-trees, standing on mounds often if not always ancient. We sometimes see groves of palm-trees besides those around the villages, but other trees are, except in some parts, rare. In Upper Egypt the valley is in as rich a state of cultivation, but very narrow and bounded by mountains of no great height, which hem it in. They form the edge of the desert on either side of the valley, which has been cut through a rocky table-land by the river. They rarely take the form of peaks. Sometimes they approach the river in bold promontories, and at others are divided by valleys with the beds of rivers which flow only at long intervals. The bright green of the fields, the reddish-brown or dull green of the great river, and the tender tints of the bare yellow rocks, beneath the deep blue sky, always form a beautiful view. In form the landscape varies little and is not remarkable; in colour its qualities are always splendid, and under a general uniformity show continual variety.

**Climate.**—The climate of Egypt, being remarkably equable, is healthy to those who can bear great heat, and who avoid the unwholesome tracts of the country, such as the

---

2 M. Jomard states that the older appellations were used for the two provinces of Benee-Sweyf and El-Muneh, though these towns had succeeded the earlier chief places after which the provinces were named. —Descr. de l'Egypte, ix. 594.
n coast, where there are extensive salt-marches.

Egypt is healthier than Lower Egypt. The least
time of the year is the latter part of autumn,
as inundated soil is drying. In the desert, at a very
distance from the cultivable land, the climate is un-
dry and unvariously healthy. Egypt, however, is
able as a permanent residence to Europeans who do
swally modify their mode of life; and it is almost
able to rear European children there; but if they
after the age of ten or a little more they do not
feel its ill effects. As a resort for invalids Egypt
recommends itself without caution. Persons suffering
sore throats and bronchitis are likely to gain benefit from
voyage, unless the season is unusually cold. The
of the desert does not in all cases suit them, the small
of sand which are inhaled increasing the irritation.
E Egypt is undoubtedly good for consumption, and a

E Egypt is undoubtedly good for consumption, and a
in to encamp near Cairo, or still better to find
and of house within the limits of the desert; and
ancient sepulchral grottoes at Thebes and other
or spring, and if the earliest cases occur towards the close of the year, one may be sure of a plague of great severity and long continuance. At first the cases are generally few, but they gradually increase and, in the hotter weather attain their maximum. The disease is not long in travelling from Alexandria to Cairo, but it rarely ascends much higher up the river, and has seldom been known at Thebes in modern times. Many medical writers have denied the contagious character of the plague, in particular Clot-Bey, a French physician, who was long chief medical officer of the Egyptian Government, and who published a treatise on the subject (Clot-Bey, De la Peste); yet the evidence on the other side is too strong to be rebutted. An epidemic of plague is greatly to be dreaded in the present circumstances of Egypt. Rapid communications would readily bring the disease to Europe, and the interests of commerce would stand in the way of the reasonable precaution of quarantine. It is stated that the plague is endemic in the marshes of Chaldea. Surely it would be well if the European Governments were to appoint a commission for the investigation of the disease and to ascertain what, if any, is the value of the sanitary measures of the Turkish Government.

Dysentery is an extremely common malady, and causes very large mortality. It may usually be traced to a careless course of diet, and especially to eating uncooked vegetables, unripe fruit, or other unwholesome food, and to drinking brackish water. Mr. Lane has published a mode of treatment which has been attended with extraordinary success (Modern Egyptians, App. E. of all later editions). Asiatic cholera visited Egypt in its westward course on the first two occasions of its appearance in Europe. According to the Government returns, which were probably below the truth, nearly 200,000 persons perished from the disease in all Egypt during the great cholera of 1848. It is remarkable that after each of these great epidemics the disease appeared a second time, but with far less destructive results. Among the diseases most dreaded by the European residents is liver-complaint. Those who abstain from alcoholic drinks, or use them with extreme moderation, escape the complaint altogether, or suffer from it in a comparatively mild form. Hemorrhoids and hernia are among the commonest maladies. Skin diseases have been at all times very prevalent in Egypt. Lepracy is now well known, but not common, unlike elephantiasis, which in more than one form has numerous victims. Small-pox was formerly very severe, but it has been checked in its virulence by vaccination. The so-called guinea-worm occurs, but is perhaps not indigenous.

Of the diseases of the eye, ophthalmia is the most formidable, from its prevalence and malignant character; yet perhaps no malady more readily yields to treatment if promptly used. Where the predisposition exists, a slight cause, such as the irritation occasioned by a grain of dust or sand, is enough to produce an inflammation, which, if not checked, inflicts a lasting injury if it does not produce blindness. For this disease Mr. Lane has published a very efficacious mode of treatment (Mod. Ey., App. E.).

Clot-Bey affirms that pulmonary consumption is extremely rare among the native inhabitants (Apercy, ii. 377), yet another physician asserted (but not in print) that he had met with not a few cases in a short practice. Asthma and bronchitis are among the common disorders. The occurrence of coup-de-soleil is not unusual, but it is rarely attended with fatal results, probably on account of the sobriety of the people. Madness is common, generally in the form of idiocy. Maniacs, alone are confined; idiots are regarded with much respect as saints, and it is probable that some persons feign idiocy to become objects of popular veneration, supported by alms. One of the Memlook

...
the constant deposit of the Nile, and the corresponding elevation of the southern part of the isthmus of Suez. The consequence of this change of level has been the ruin of places on the shore of the Mediterranean, the extension of the salt-marshes, and the drying up of a considerable part of the northernmost portion of the Gulf of Suez. The bed of the Red Sea may be traced for several miles north of Suez, which now stands at the head of the western gulf, and places far north of that town were on the coast in ancient times.

The form of the plain and valley inclosed by the deserts is remarkably regular. In Lower Egypt the cultivable land little exceeds the limits of the ancient Delta, but greatly exceeds those of the space between the two remaining branches of the Nile. The northern coast is protected by shoals and a low range of sand-hills. To the south of these are extensive salt-marshes and lakes, or waste tracts, and beyond, the cultivated land. The deserts on either side are of low elevation. To the east of the ancient Delta, a valley, the Wadis-es-Tunaylit, is in course of being reclaimed by the Sweet-Water Canal.

The form of the valley, or Upper Egypt, may be best seen on the map; its leading peculiarities may be noted. Its course is nearly north and south until just within the border of the Thebans, when it takes a north-east direction as far as the town of Girgh, and then turns due east as far as Kue, from which town it resumes its former direction. The mountains and desert on the western side throughout Upper Egypt, that is, above Cairo, are generally further from the river than those on the eastern side, which frequently reach to the water's edge. The difference is most remarkable as far as the town of Farnoosh, by the course of the river about 350 miles above Cairo, and about 70 miles below Thebes. Near Farnoosh begins a continuous series of canals, which flow parallel to the Nile, and near the Libyan chain, until they terminate in Lower Egypt, not far north of Cairo. Above Farnoosh, the eastern mountains recede as far as little above Thebes, and the western mountains gradually approach the Nile. Halfway between Thebes and the First Cataract, the cultivable soil is equally narrow on each bank. The greatest breadth of the cultivable land, all of which is not cultivated, on the western bank seldom exceeds about 8 or 10 miles, and on the eastern bank, about 5 miles, but it is usually much narrower.

There is in the modern Nile valley a striking deviation from the uniform character of the country. About 70 miles above Cairo, by the course of the Nile, an opening in the Libyan range leads to a kind of oasis, the Fayoum, a fertile tract, lying in a hollow of the desert, and having at its further extremity a great lake of brackish water.

The Nile—The chief natural feature of Egypt is the Nile, and the great phenomenon of the country the yearly inundation. With the ancient inhabitants the river had, according to their usage with such names, two appellations, sacred and common. The sacred name was Hapi, the same as that of one of the four genii of Ament (Hier. i., 12, 13, 18, 24); the probable meaning is "the concealed" (Brugsch, Geogr. Inschr., l. 77). The profane name was Atur, or Aur, usually with the epithet, as the great. The two forms, of which the first appears to be the older, the second the younger, mean "river," and are equally the case with the demotic and Coptic forms of Aur (Ed. p 78). There are at least three names of the Nile in the Bible,—Yob, (797, 798), the same as the Egyptian name last mentioned, and probably of Egyptian derivation; Sheshen (876, 877, 875), the black; and "the river of Egypt," Shione, or "the Euphrates" (791, 792), spoken of as the western limit of Palestine, and so the eastern limit of Egypt, as either a desert stream at Rhinocorus, now El-Areesh, or the Pelusiac or easternmost branch of the Nile.

The Greek and Roman name Nilos, Nileus, is certainly not traceable to either of the Egyptian names of the river, nor does it seem to be philosophically connected with the Hebrew ones. It may be, like Shishor, indicative of the colour of the river, for we find in Sanskrit, Nilus, "blue," probably especially "dark blue," also even black, as Nilava, "black mud." The two great confluents of the Nile are now called the Bahr-el-Abyad, or "White River," and the Bahr-el-Azrak, or "Blue River," and the latter most nearly resembles the Nile in Egypt. As already noticed, Afeneos, in the Odyssey, is the name of the Nile (mas.) as well as of the country (fem.).

The Arabs preserved the classical name of the Nile in the proper name En-Neel, or Neel-Misr, the Nile of Misr (Egypt). The same word signifies "narrow." The modern Egyptians commonly call the river El-Bahr, "the sea," a term also applied to the largest rivers, and the inundation "the Nile," En-Neel; and the modern Arabs call the river Bahr-en-Neel, "the river Nile." The course of the Nile has already been noticed in speaking of the form of the Nile valley. In ancient times the Delta was watered by seven branches; now there are but two, the other ancient branches being canals not always navigable. The ancient branches were, beginning at the west, the Canobos, Bolbute, Sobennute, Pathymeian, Mendesian, Tantian, and Pelusiac, of which the modern Rosetta and Damatta branches represent the Bolbute and Pathymeian.

The mean breadth of the river in Upper Egypt may be put at half a mile to three-quarters, except where large islands increase the distance. In the Delta the branches are generally narrower.

A remarkable change has been ascertained to have occurred in the level of the Nile above Gebel-es-Sibalsh (near the ancient Sibias, more than 80 miles south of Thebes), and throughout part of Nubia. Indications of this change were first observed by Professor Leguan, who discovered hieroglyphic inscriptions on rocks at the Cataract of Semna, not far above the Second Cataract, showing that the river attained a much higher level in the time of Dynasties XII and XIII, before B.C. 2000. He gives the difference of the mean water-level at Semna as 7 to 20 metres, or 23 to 65 feet English. He observes that the whole level of Upper Nubia was anciently greater, and similarly that of Lower Nubia between the First and Second Cataracts, but that in this second tract the present level was attained since the time of Thothmes III, of Dynasty XVIII (A Camb. Journ. i., 81, 1843). Sir Gardner Wilkinson pursued the inquiry in a paper in which he argued that the cause of the change of level which he traced in the Upper Thebans was the breaking of a rocky barrier at Gebel-es-Sibalsh, where the low mountains on either side confine the river to a narrow channel (Trans R Soc. Edinb., 110th Sept. 1844.). Sir Gardner Wilkinson took the inquiry a step further in a paper in which he argued that the cause of the change of level which he traced in the Upper Thebans was the breaking of a rocky barrier at Gebel-es-Sibalsh, where the low mountains on either side confine the river to a narrow channel (Trans R Soc. Edinb., 110th Sept. 1844.).

The water of the Nile differs considerably in appearance and purity at various seasons of the year. A little after midsummer it becomes very turbid, and not long afterwards...
it assumes a green colour for more than a fortnight, owing to the quantity of vegetable matter which it brings down from its upper course. It then resumes its turbid character for the period of the race, and retains it, though in a less degree, for the remaining portion of the year, until the following midsummer. The water is extremely sweet, particularly in its turbid state. A careful filtration destroys its peculiar flavour, and the best method is to allow it to settle in the porous jars manufactured in the Island of Er-Rôdah, near the mouth of the river, which attains to a certain height in feet or metres, at certain dates. The river attains its greatest height in July, 2, 1799, to April 6, 1800, during a good inundation. The water presents much argillaceous matter, taken from the banks of the Nile, and carried by the waters of the inundation to distant tracts it loses a quantity of sand in proportion to the distance, so that, when the distance is very considerable, the argillaceous matter is nearly pure; and thus the soil presents this matter in the different degrees of purity which the arts of potting and brick-making require (Deser. de l'Egypte, xx. 162-164).

The Nile shows the first signs of rising in Egypt about the time of the summer solstice. At Khartoom, where the White and Blue Nile join, the beginning of the increase is observed early in April (Clot-Bey, p. 36, 37). The slowness of the rise in the earlier stage causes this difference. Usually the regular increase does not begin in Egypt until some days after the summer solstice, and the inundation begins about two months after that solstice. The river attains its greatest height at, or not long after, the autumnal equinox, and then, falling more slowly than it had risen, sinks to its lowest point at the end of nine months, when it remains stationary for a few days, until it begins again to increase. The inundation continues rather longer than it naturally would do, because the waters are retained for some time upon the land by closing the mouths of the canals (see the table, Deser. de l'Egypte, xvii. i. 630, seqq., for the details of the state of the Nile, from July 3, 1799, to April 10, 1800). The river's banks being a little higher than the rest of the cultivated soil, the water is conveyed by canals or cuttings, and does not pour over the banks.

The inundations vary considerably, and, by either falling or rising too great a height, cause much damage and distress. In the Description de l'Egypte (xvii. i. 628-629) there is a table of 60 inundations, of which 11 were very high, 30 good, 16 feeble, and 9 insufficient. This table was taken from the official records of the Nilometer on the island of Er-Rôdah, near Cairo, and comprehends the inundations of A.H. 1150-1215 (A.D. 1737-1800).

The Nile rises about 40 feet at the First Cataract, about 56 at Thebes, about 25 at Cairo, and about 4 at the Rosetta and Damietta mouths during a good inundation (Encyclopaedia of Egypt, i. 89; Deser. de l'Egypte, xvii. i. 576, 577). When it is said, however, that the river has attained to a certain height in feet or cubits, the height at the Nilometer of Er-Rôdah above-mentioned is meant; and by ancient writers, that of the river at Memphis, which was situated on the western bank, a little higher than Er-Rôdah. If the river do not attain a greater height than 16 or 20 feet, the inundation is scanty; if only 2 or 4 feet more, insufficient; if it attain to 24 feet, or a greater height, not exceeding 27 feet, the inundation is good; but a greater rise must be characterized as a destructive flood (Deser. de l'Egypte, xvii. i. 616). Sometimes the inundation has failed altogether; as for seven years (A.H. 1457-1464) in the reign of the Fatimiee caliph El-Mansour bi-l-lâh, when there was a seven-years' famine (see below, page 752) and low inundations always cause dearth. Excessive inundations, on the other hand, produce, or at least foster, the plague and murrain; so that a variation of a few feet is productive of the most serious consequences.

The current, when the Nile is low, has been estimated at about 2 miles in the hour, and at about 8 miles an hour when it is high. The volume of water which the Nile pours into the Mediterranean in 24 hours is as follows, according to Mr. Linnard:—

Although the water is abundantly charged with alluvium throughout the year, and especially during the inundation, the annual deposit by the river, except under extraordinary circumstances, is very much smaller than might be supposed. Various computations have been made as to the exact deposit left in a century on the land, but they have not usually differed above an inch. If, however, we compare the quantity of deposit on certain very ancient structures, of which we know the date, we shall find that the amount has materially differed in various places. Such differences are the natural results of irregularities in the river's course, of the strength or weakness of the current at particular places, of the nature of the country, and many other disturbing causes. The mean ordinary rate of the increase of the soil of Egypt has been calculated by Mr. Lane as about 44 inches in a century. M. Girard, in the Deser. de l'Egypte, makes it "very nearly" 126 millimètres, or 4'960 English inches. (For a remarkable instance of rapid deposit, see the Englishwoman in Egypt, i. 152-154, and plan, p. 125.)

The cultivable land of Egypt must be regarded as wholly the deposit of the Nile, but it is vain to attempt a calculation of the period at which this process began, since we cannot conclude that the same rate has always obtained, and we must suppose that the causes at first in operation were very different from those which now regulate the phenomenon.

At the time of the French occupation of Egypt it was found that the cultivable soil occupied only 6921 square miles, or somewhat more than two-thirds of the whole space included between the deserts, but the quantity actually under cultivation did not exceed 5500 square miles, or six-elevens of the entire surface. This proportion has since not materially changed. It was not always so, and the deficiency of the population is the principal cause that so large a proportion of the soil which might possibly be brought into a state of culture is left uncultivated.

Throughout Egypt the cultivable soil does not present any very great difference, being along the line of the river; it contains, however, more sand near the river than at a distance from it. Towards the Mediterranean, its...
quality is injured by the salt with which the air is impregnated, and therefore it is not so favourable to vegetation. Thus condition, however, is not usually found far south of the sea, or the salt-marshes and lakes, which intervene for the most part between it and the land. In Lower Egypt we find the greater portion of the neglected tracts principally to the east and west of the modern Delta, and in its northern portion. In Upper Egypt the narrowness of the valley, and the more numerous population, preserve the country in a better state of cultivation, and the soil is somewhat richer. The largest uncultivated tracts lie on the western bank, where the valley is broadest, and in places where the great canal running parallel to the Nile has fallen into a state of neglect.

Common of the Country.—Although some of the accounts of the classics may be deemed exaggerated when they speak of the population and prosperity of Egypt, we cannot accuse them of errors, except in the number of towns and of the inhabitants of the country, for the monuments show us how rich was Egypt under native rulers, and indicate to what causes this condition may reasonably be assigned. From the time at which the Great Pyramid was built to the Persian invasion, a period of between 2000 and 3000 years, the population of Egypt and its extent of cultivated land far exceeded what they are in the present day. The country does not seem to have been over-peopled; and many causes conduced to prevent this, particularly the serious wars in which the Pharaohs engaged. The long and desolating struggles with the Assyrians and Persians inflicted a severe blow on the interests of the country. Under the Macedonians it recovered much of its former prosperity; and when the Romans held Egypt, it was one of their most productive provinces, and a granary of the empire. During the Roman rule various political causes contributed to the decline of the population. After the Muslim conquest this decay continued almost uninterruptedly until the time of the Fatimides; but from that time until the Turkish conquest the rulers of the successive independent dynasties generally governed the country with a regard for its interests, and cannot be accused of the systematic tyranny and misrule of the Turkish pashas. There was a temporary recovery under the independent or semi-independent Memluk rulers before the French invasion, and in spite of much of the Turkish system the country has again made good progress during the government of the family of Mehemet Ali. To over-taxation, forced labour, and needless wars,—in other words, government in a Turkish sense,—must be attributed the present misery of the peasant population, and the want of lands enough to cultivate the soil.

Physical causes have had far less to do with the impoverishment of Egypt than political ones. The elevation of the tract north of the Gulf of Suez, with the depression of the north coast of Egypt, has much diminished the cultivable soil in the Delta, by increasing the salt lakes and marshes which occupy its northern portion. There is, however, no greater fallacy than to suppose that the sands of the deserts have done injury by encroaching upon the alluvial tracts, and that once fertile regions are buried beneath them. In some places undeniably they have encroached upon the cultivable land, particularly where, as in the case of the canal of the Red Sea, the neglect of the Government had withdrawn the inundation, but no sooner was the Sweet Water Canal opened than fertility returned. On the other hand the deposit of the Nile has been constantly, in almost every part of the country, encroaching upon the deserts and diminishing their extent. It is neglect that has permitted the sand to drift over the soil where there have been no labourers to cultivate it. Above Gebel-es-Silasieh, in Upper Egypt, the change in the level of the river has placed cul-
tivable soil almost wholly beyond the reach of the inundation, and thus made agriculture very laborious, but this is only for the space of about 40 miles in Egypt, where the extent of the cultivable soil must always have been small on account of the narrowness of the valley. The failure of five of the seven branches of the Nile is partly due to the neglect of the Government, as they might all have been re-tained as constantly running canals. And the decay of the great canal which runs parallel to the Nile throughout the chief part of Upper Egypt is traceable to the same cause.

Under the government of Mehemet Ali a great engineering work was begun with the view of bettering the condition of Egypt. This was the construction of a barrage across both branches of the Nile at the point of the Delta, in order to regulate the inundation, and thus render the country more fertile and easy of cultivation. After being abandoned this work is now to be completed. Its operation will on the whole be beneficial, although undoubtedly the power to be thus acquired by the khedive, of regulating the inundation for the benefit of his lands without reference to small proprietors, will be productive of much injustice. Egypt can never regain her ancient prosperity without a radical reform. The country has been governed under the Turks upon the system of getting the maximum of revenue from a peasantry allowed the minimum of sustenance. This is what is meant by the high-flown phrases one hears about the welfare of Egypt. The welfare of the population has never been contemplated. The feudal peasantry are kept at starvation-point, and no one propers but the tax-gatherers of all grades, who constitute the richer class. Yet Egypt is better governed than the other provinces of the Turkish empire which enjoy a purely Turkish administration, for it is held not on the uncertain tenure of an ordinary pashalik, but as a copyhold which it is the interest of the tenant to keep in decent repair.

Agriculture.—Under the Pharaohs Egypt was an agricultural country, and both commerce and manufactures were comparatively unimportant. The main energies of the people were expended in turning to the best account a soil of unrivalled richness, annually watered and renewed by the river. This natural policy was the true one for the prosperity of the country. From the sculptures and paintings of the tombs, we form a clear idea of the agriculture of the ancient Egyptians, while the classical writers give us information respecting the tenure of land, and the laws affecting the cultivators. In the representations of the tombs which picture the daily life of the great proprietors of land, we see what especial attention they paid to the processes of agriculture. We see them constantly overseeing the labourers, and thus watching the interests of their lands. They were especially anxious to conduct the water of the Nile over those tracts which were not above its level at different periods of the year, and to raise it by manual labour to the higher portions of the land. In their canal-system they displayed mechanical skill, as well as in the construction of dams and dikes to retain the water upon the lands; but for raising water they seem to have been contented with the rudest contrivances. Indeed we know of but two methods that were employed in raising water,—the use of the simple machine called in the present day the abdshof, and buckets carried by men. The ordinary abdshof still employed is of the same form as that used by the ancient Egyptians. It consists of a pole resting upon two columns of brick or mud, and having at one extremity a weight, and at the other a rude bowl-shaped bucket suspended by a stick. A man stands beneath it, and pulling down the bucket to the water raises it again, assisted by the weight. (For the ancient form of the abdshof, see ANC. EY, li. 4; for the modern, Mot. Eq., chap. xiv.)
Immediately after the water of the inundation had subsided, the land was ploughed or broken up by the loo, and sowed the seed being sometimes trodden in by goats driven over the field for the purpose. Wheat being the most important field-produce, we find the various agricultural processes connected with it frequently represented. Besides the ploughing and sowing, the harvest is depicted, the reapers cutting the wheat, just below the ear, the ears left in nets or baskets by men or on asses to the threshing-floor, where they were threshed by kine. Sometimes the wheat was bound in sheaves. The same or similar processes with reference to other kinds of grain are portrayed in the tombs, in which we also find curious representations of the vineyards and gardens. The vineyard was not the least valuable part of an estate. Egypt was famous for its wines in the days of the Greeks and Romans, and it is evident that wine must have been prized in earlier times from several kinds being enumerated in the inscriptions, and from its always being seen at the feasts. Besides the vine, other fruit-trees were cultivated, and especially the date-palm. The gardens were often extensive, and were laid out with great formality, partly in consequence of their being watered in the same manner as the fields generally, and contained tanks for fish as well as for purposes of inundation. The Egyptians paid great attention to preserving fish, and the produce of the fisheries of one great artificial lake, that of Moeris, formed an important branch of the revenue. There were also tracts left to reeds, which, if not planted, were at least carefully maintained, on account of their value for manufactures, and as covers for wild-fowl.

Diodorus Siculus states that anciently the land was the property of the priests, of the king, and of the military class (i. 73), and the monuments leave little room to doubt that such was generally the case; for though there were no castes, the upper classes consisted of priests and military officers, and the son usually followed his father's profession. It is stated in the Bible that Joseph purchased the whole of the land of the Egyptians for food during the famine, and gave them seed to sow it, claiming a fifth of the produce as the king's right. The land of the priests alone was not purchased.

The agriculture of the modern Egyptians differs little from that of the old inhabitants. In one respect it is the converse: the ancients excelled in the management of dikes and dams, and raised water only by the converse: the ancients excelled in the management of dikes of course makes the water chiefly and partly in having a hollow wheel instead of the wheel act of tyranny to which even the history of Egypt scarcely ascribed.

The ancients excelled in the management of dikes of course makes the water chiefly and partly in having a hollow wheel instead of the wheel used by the present ruler. (Mod. Eg., xiv.) Steam-pumps are now largely used.

The culture of cotton was introduced by Mehemet Ali with a view to promote his manufacturing schemes, and the Turkish grandees have found it a source of temporary profit. During the American War the profit was at its height, but subsequently it declined. The necessity of constructing dams to exclude the Nile water from the cotton-growing fields has rendered the inundations destructive, and the speculation seems on the whole to have injured the welfare of Egypt.

The agricultural implements of the modern Egyptians are rude in construction, and similar to those anciently employed in the country. One of these, however, was not known to the earlier inhabitants. This is the n'org, a machine "in the form of a chair, which moves upon small iron wheels or thin circular plates, generally eleven, fixed in a similar machine, which is composed of a horizontal wheel turned by a pair of cows or bulls, or by one, and connected with a vertical wheel which is on the same axis as another around which are earthen pots in which the water is raised and poured into a trough. The tiboot is a similar machine, which differs from the sikkiah principally in having a hollow wheel instead of the wheel with pots, in the jaunts or felhes of which the water is conveyed. Sometimes a kawch is employed, which is a bucket like that of the sikkiah, having four cords by which two men dip it into the river or canal and raise the water. (Mod. Eg., xiv.) Steam-pumps are now largely used.

The "re" lands (or those which are naturally inundated) are, with some exceptions, cultivated but once during the year. After the waters have retired, about the end of October or beginning of November, they are sown with wheat, barley, lentils, beans, lupine, chick-peas, &c. This is called the "shatree" (or winter) season. But the "shatree" lands (or those which are too high to be subject to the natural inundation), and some parts of the irrigated, are sown at the same period as the rei lands, generally with wheat or barley. Secondly, in what is called the "safieen," or in the southern part of Egypt the "keydee," or in the "safieen" season, or period of the rise of the Nile, commencing about or soon after the summer solstice, they are sown with mullet ("dural safieen"), or with indigo or cotton, &c. Finally, in the "demerech" season, or period of the rise of the Nile, commencing about or soon after the summer solstice, they are sown with mullet again, or with maize ("dural shammee"), &c., and thus passed with a third harvest. (Mod. Eg., Syst.) The ancient Egyptians made the same, or a similar preparation of the date-palm. The gardens were often extensive, and were surrounded, and from its always being seen at the feasts. Besides the vine, other fruit-trees were cultivated, and especially the date-palm. The gardens were often extensive, and were laid out with great formality, partly in consequence of their being watered in the same manner as the fields generally, and contained tanks for fish as well as for purposes of inundation. The Egyptians paid great attention to preserving fish, and the produce of the fisheries of one great artificial lake, that of Moeris, formed an important branch of the revenue. There were also tracts left to reeds, which, if not planted, were at least carefully maintained, on account of their value for manufactures, and as covers for wild-fowl.

Diodorus Siculus states that anciently the land was the property of the priests, of the king, and of the military class (i. 73), and the monuments leave little room to doubt that such was generally the case; for though there were no castes, the upper classes consisted of priests and military officers, and the son usually followed his father's profession. It is stated in the Bible that Joseph purchased the whole of the land of the Egyptians for food during the famine, and gave them seed to sow it, claiming a fifth of the produce as the king's right. The land of the priests alone was not purchased.

The agriculture of the modern Egyptians is in a miniature Egypt. It is intersected by numerous small channels which are filled by one or more water-wheels. By these channels the water is spread over the garden, divided by them into many small compartments, edged with ridges of earth. This system of course makes it very difficult to keep a garden in good order, and no great variety of flowers is cultivated.

Though Mehemet Ali was very desirous to encourage manufactures, he did not endeavour enough to apply modern science to the improvement of agriculture, and he did not succeed in getting the promise of Pasha, who succeeded him, always maintained that the country should be agricultural rather than manufacturing, and introduced important improvements during his father's government. This system has been steadily pursued by the present ruler.

Before the time of Mehemet Ali a kind of feudal system prevailed, and much of the land was held by small proprietors under the protection of the great emeere. By the massacre of the Memlooks, the pasha destroyed feudalism, and arbitrarily seized almost all the landed property, rendered private tenure of land a most rare condition. He allotted to those whom he thus unjustly dispossessed annual pensions for life, as the only compensation for an act of tyranny to which even the history of Egypt scarcely affords a parallel (Mod. Eg., ch. iv.). Those whose lands were not confiscated yielded them up through fear, and buried their title-deeds, which are yet so concealed. A system of government in which the supreme overthrows such acts, and subordinate governors perpetrate them, in defiance of the Muslim code and Arab jurisprudence, demands the most thorough and searching reform.

Lakes.—Egypt has always been famous for its lakes,
which have either aided commerce, or supplied the inhabitants of the country with fish and wild fowl, or with valuable vegetable productions, or assisted in regulating the effects of the inundation. All have enriched the land in some one of these ways, and thus they have been important sources of its natural wealth.

Beginning our examination at the north-western extremity of Egypt, we first observe the lake now called Boheyeret-Maryoy, and anciently Lake Mareote. This is an extensive salt marsh rather than a lake, except during the inundation, when its contents are augmented by filtration. Anciently this lake was navigable, and thus contributed to the commercial importance of Alexandria. The country around was cultivated, and produced the famous Mareotic wine. The relations of various travellers show that it was still a lake during the 15th and 16th, and even towards the close of the 17th century; and Villamont in 1590 mentions that in his time the fishermen produced a considerable sum (Deer. de l'Egypte, xvi. 201). When, however, the French army conquered and occupied Egypt (1798-1801) they found its basin to be "a sandy plain, of which the lower portion retained the rain-water, which remained there for a great part of winter" (Id. 200, 201).

On the 4th of April 1801 the English army, which was co-operating with that of the Grand Vizir against the French garrison of Alexandria, cut the dikes of the canal of that city, and admitted the waters of the Lake of Abou-Kee into the ancient bed of Lake Mareote, in order to cut off the water supply of the besieged (Id. 201, 202). The basin of the lake being partially inhabited, some loss of life and property was the result of this act, which has reasonably been much called in question. The unhealthiness of Alexandria is also traceable to the formation of this marsh.

The precedent thus set has been twice imitated, first by the Turks in 1803, and a second time by the English army under General Fraser in 1807. At the present day the lake or marsh is unprofitable, and its shores are uncultivated and uninhabited, the whole wearing the most dreary aspect.

To the north of Lake Mareote is situated that of Abou-Kee, Boheyeret-Abou-Kee. It is the northern most portion of the other lake, from which it is separated by the Mahmoodeyeh Canal (which here occupies the line of the older Canal of Alexandria), and the embankments or dikes which form its banks. It is very small, nowhere measuring 10 miles across, and extremely shallow, usually not exceeding 3 feet in depth. The water is salt, being chiefly derived from the sea, from which the lake is separated by a narrow strip of oolite, though at times the two are confluent, and on the eastern by a similar strip of far less breadth, the shore of the memorable Bay of Abou-Kee.

To the east of the Lake of Abou-Kee is that of Atkoo, Boheyeret-Atkoo. It spreads when full nearly to the town of Rosetta, and is separated from the sea by a narrow neck of land on which stands the large village of Atkoo.

The easternmost of the lakes of Egypt is Boheyeret-el-Menzeleh, which greatly exceeds the others in size. It extends from near the Demiutta Branch of the Nile to the mouth of the old Tanitic Branch, now called the canal of El-Moizz, which passes through the lake to the sea. It also receives the waters of the canals which were once the Mendesian and Pelusian Branches. The northern shore is separated from the sea by an extremely narrow strip of land. At its south-eastern extremity is a long marshy creek extending into the desert. Its average length is about 40 miles, and its average breadth about 15.

The easternmost of the lakes of Egypt is Boheyeret-el-Menzeleh, which greatly exceeds the others in size. It extends from near the Demiutta Branch of the Nile to the mouth of the old Tanitic Branch, now called the canal of El-Moizz, which passes through the lake to the sea. It also receives the waters of the canals which were once the Mendesian and Pelusian Branches. The northern shore is separated from the sea by an extremely narrow strip of land. At its south-eastern extremity is a long marshy creek extending into the desert. Its average length is about 40 miles, and its average breadth about 15.

The depth is greater than that of the other lakes, and the water is salt, though mixed with fresh. Upon the surface are numerous islands, and the whole lake abounds in reeds of various kinds. It supports a considerable population of rude fishermen, who dwell in villages on the shore and islands, and live upon the fish of the lake. The reeds are cover for water-fowl of various kinds, which travel in great numbers, and wild boars are found in the marshes to the south. (Mod. Eg. and Thes., p. 446.)

The Lake Serbonas, well known in former times as having swallowed up those passing over its marshes concealed by shifting sands, is now dry, and cannot be any longer included in the list of the lakes of Egypt.

Besides the lakes above mentioned are those called the Bitter Lakes, which should rather be termed marshes, occupying part of the ancient bed of the Red Sea between Suez and Lake Menzeleh, and also the Natron Lakes. The latter, which are very small, are situate in a valley of the western desert, not very far from the river, they will be noticed below.

In Upper Egypt there is but one lake of importance. It is the Birket-el-Karn, or Lake of El-Karn, at the extremity of the Fayiyoum, which is, as already mentioned, an arm on the western side of the river, to which an opening in the mountains leads. The lake is about 35 miles long, and its widest part a little exceeds 7 miles, according to Sir Gardner Wilkinson, while in several places it is considerably narrower. About the middle is a single island. The depth is not great, for the same author, who "sounded in several places," "found that is considered the deepest part to be only 20 feet" (Mod. Egypt and Thes., p. 341-5). Its level is far below that of the Nile, as the bank of the river at Benc-Sewef, at the entrance of the valley leading to the Fayiyoum, is upwards of a hundred feet higher than the water of the lake (Idem. 346). The shores are barren or uncultivated, the northern is desert and bounded by sandy mountains, the southern was in ancient times partly cultivated. The water is brackish and unhonorable, though the fishermen, of whom there are a few, drink it.

The famous Lake Mauro lay between the Feiyoom and the Nile, not far from the river. It was an artificial work executed by Amenemhat III., of Dynasty XII. The irrigation of neighbouring tracts was regulated by it, and its fisheries formed an important part of the revenue. After the subjugation of Egypt by the Romans its dikes were neglected, and by degrees it became ruined. Its position and extent were considered doubtful, until M. Lantin's excellent memoir, published by the Egyptian Society of Cairo, established these points most satisfactorily from the remains of its basin, which are yet traceable (Memoire sur le Lac Mauro, Soc. Eg., 1843). 

Canals.—The canals of Egypt deserve especial attention from their great importance in extending the beneficial influence of the inundation. In Lower Egypt we find, beginning from the west, first the Mahmoodeyeh Canal, which connects Alexandria with the Rosetta Branch, taking yellow within instead of being red or pink, and come into season after those grown on the banks of the Nile.
a similar direction to that of the ancient canal which it has succeeded. It was dug under Mahomet Ali; and although not quite 1000 feet broad, about 12,000 labourers are said to have died in ten months while the work was in progress (Englishwoman in Egypt, i. 47, 48). This is well known to be a tolerably accurate statement of the losses experienced by the unfortunate workmen, and is only one of the many incidents of our own times affords of that reckless disregard of human life, which is one of the worst traits of Turkish character.

Between the Rosetta and Damietta Branches are several canals, some of which are of importance, particularly the short canal of Maucof connecting the two branches, not far from the point of the Delta. To the east of the Damietta Branch are others, of which the most remarkable occupy the beds of the Tanitie and Pelusiac Branches, which have been cleared to a sufficient extent to form canals. The former of these, which lies to the westward of the latter, is called the Canal of EL-Mousa, the first Fatimieh caliph who ruled in Egypt, having been dug by his orders, and the latter bears the name of the Canal of Abu-Munegga, a Jew who executed this work, under the caliph El-Amir, in order to water the province called the Hilah. The last-named canal is connected with the remnants of that which formerly joined the Nile and the Red Sea. Of this important work the greater part was destroyed through neglect, but it has been restored, as the Sweet Water Canal, in order to supply the establishments on the Suez Canal with fresh water. It was of the Pharaonic times, having been begun by Pharaohs, or Sesostris, continued by Neku, and by Darius Hystaspis, and at length finished by Potemly Philadelpbus.

The extent and character of the great canal called the Bulir-Yosof, or Hier of Joseph, which runs parallel with the Nile on its western side, from a little below Cairo to near Alexandria, by the river of a little more than 50 miles, render it the most important work of the kind in Egypt. It is a continuous series of canals rather than one canal. Although the Joseph whence it takes its name is the celebrated Saladin, or Salib-ed-deen, yet it is related that he merely repaired it, and it is not doubted to have been of a much earlier period. Most probably it was executed under the Pharaohs. In the present day it is not navigable except during the season of the inundation, and at other times is dry in various places. Its restoration would not be a work of extreme difficulty, and would greatly benefit the commerce and agriculture of the country, perhaps more than any other undertaking of the kind.

1 A note from the eighth edition of this work is here reprinted in substance. — Writers on the East have not generally been careful to distinguish the Turkish and Arab national character, and the former has thus had the advantage of the virtues of the latter, which has received in return the odium of the other's vices. The remarkable characteristics of Arab character are high honour, generous hospitality, and humanity, coupled with much direct in small matters not connected with points of honour, carelessness as to religion, though not irreligion, and the too frequent excesses of womanly love. The Turkish character is as strongly marked by treachery, often of the blackest kind, little hospitality, pecuniary indifference to strangers, cruelty and disregard of human life, bigotry as to their religion, which is now giving way to democratism, and the same love of plunder which is so common among the Arabs, as well as darker vices unknown to them, which have rendered the Turkish name a by-word in the East, as well as in the West. The conquistadores of the Arabs were not marked by desperation; their rule preserved the philosophy of Greece, which was welcome at the court of Bagdad when it was known in Europe. Arab art was contemptible, and so was its manufactures. Athens, Alexandria, and Antioch; the arts have decayed. Until they held Egypt and Mesopotamia, these were the richest countries of the world, now they are half deserts. All these are facts which can be proved.

Vegetable Products—Egypt differs from most other countries in having neither woods nor forests. Besides the palm groves, we rarely see even a grove of trees, except in Lower Egypt. The largest common trees are acacias, sycamore-fig-trees, and mulberry-trees, all of which are frequently planted on each side of the great roads near Cairo; and the most beautiful trees are the date-palm and the banana. The beauty of the country is caused by its variety of date-palm; for its lowest branches are annually cut, which causes it to grow high, and renders its head of elegant form. When wild, this tree has a far inferior appearance, being low, and having long ragged branches reaching to the ground; and its dates are small and poor in flavour. The Turkish date is a very different tree, having two great branches, each of which divides into two other branches, a subdivision which continues still farther. The weeping-willow, myrtle, elm, and cypress are found in the gardens and plantations, with various trees bearing the fruits to be next mentioned; and the tamarisk is to be seen everywhere.

The most common of the fruits are dates of various kinds, which are sold half-ripe, ripe, dried, and pressed in their fresh most state in mats or skins. Many different sorts are enumerated as known in Egypt. The dependencies produce, and not Egypt, the produce of the lower dates. The hotter and drier climates of the Oases and Lower Nubia best suit the date-palm; and the pressed dates of Seewah, the ancient Oasis of Jupiter Ammon, are among the most esteemed. The grape is a common fruit, but wina is not made from it on account of the prohibition of Mohammed. The Fayoum is celebrated for its grapes, and chiefly supplies the market of Cairo. The most common grape is white, of which there is a small kind far superior to the ordinary sort. The black grapes are large, but comparatively tasteless. The vines are trained on trelliswork, and form agreeable avenues in the gardens of Cairo; but little attention is paid to their culture, the common fault of Egyptian agriculture and gardening, due to the generosity of nature and the indulgence of the inhabitants.

The best known fruits, besides dates and grapes, are figs, sycamore-figs, and pomegranates, apricots and peaches, oranges and citrons, lemons and limes, bananas, which are believed to be of the fruits of Paradise (being always in season), different kinds of melons (including some of aromatic flavour), and the refreshing water-melon, mulberries, Indian figs or prickly pears, the fruit of the lotus, and olives. Many of these are excellent, especially the figs and melons. The trees and plants which produce most of them are chiefly confined to the gardens. The cactus bearing the Indian fig is extremely common, and forms the hedges of gardens and plantations.

The general plan of an Egyptian garden has been already described. Although seldom in good order, such a garden is often picturesque, having a few date-palms and bananas, and perhaps overlooked by one of those houses of the old style of architecture which are rapidly disappearing. No great variety of flowers is cultivated. Among the more usual are the rose (which has ever been a favourite among the Arabs), the jasmine, narcissus, lilac, hydrangea, chrysanthemum, convolvulus, geranium, dahlia, basil, the hibiscus plant (Lavonos alba, or Egyptian privet, which is said to be a flower of Paradise), the helianthus, and the violet.

The vegetables, &c., are very common and of various kinds, so that we cannot enumerate the Children of Israel longed for them in the desert. The principal are beans, pease, vetches, lentils (of which a pottage is made, which is the common food of the Nile boatmen), lupins, chick-pease, the loobiribh (Dolichos lubia), fenugreek, mallow, the baimyl (Bissicous esculentus), spinach, waterlily,
melookheeyeh (Corolars otiorius), leeks, onions, garlic, celery, parsley, chicory, eres, radishes, carrots, turnips, cole-casns, lettuce, cabbage, fennel, gourds and cucumbers (both of several kinds), the tomato, the egg-fruit or badgin (black and white), caraway, coriander, camum, anised, and red pepper.

The chief field-produce is wheat (which is more grown than any other kind of corn), barley, several sorts of millet, maces, rye, oats, clover, peas, the sugar-cane, rues, two species of the tobacco-plant, and cotton, now largely cultivated. The sugar-cane is extensively cultivated, and excellent sugar is manufactured from it. There are fields of roses in the Fesoum, which supply the market with rose-water. The tobacco produced in Egypt is coarse and strong compared with that which is used by the middle and upper classes and imported from Syria and Turkey. That of Syria is considered the best. Of textile plants, the principal are hemp, cotton, and flax, and of plants used for dyeing, bastard saffron, madder, wood, and the indigo plant. The intoxicating hashsheeh, which some smoke in a kind of water-pipe formed of a cocoa-nut, two tubes, and a bowl, seldom used for any other narcotic, is not, as has been erroneously supposed, opium, but hemp. The effect is most baneful. The leaves of the hemp plant are used to impart a bright red colour to the palms of the hands, the soles of the feet, and the navel of both hands and feet, of women and children, the hair of old ladies, and the tails of horses. Indigo is very extensively employed to dye the shirts of the poorer classes, and is, when very dark, the colour of mourning; therefore, women at funerals, and generally after a death, smear themselves with it. Oil is extracted from the seeds of the cotton plant, hemp, calewort, the poppy, the castor-oil plant, sesame, and flax.

The high coarse grass called balfeh (Poa cynosuroides) grows in great quantity in waste places and among ancient ruins.

Many kinds of reeds are found in Egypt, though, if we compare the representations in the ancient tombs with what we see in the present day, it is evident that they were formerly much more common. That they should be wasted away was prophesied by Isaiah (xxix. 6, 7). The famous bylius, or papyrus, from which paper was manufactured, appears to be nearly, if not quite extinct, since Sir Gardner Wilkinson had never seen it (Mod. Eg. and Thebes, l. 441). M. Delile, in his excellent account of the Egyptian flora, merely mentions it by name in his list as the Cyporum Papyrus, called in Arabic Papiru and found at Damieta, but gives no figure of it. The lotus, greatly prized for its flowers by the ancient inhabitants, is still found in Egypt, though it is not common. The French naturalist above mentioned enumerates three species which formerly grew in that country, one with white flowers, another with blue, and a third with rose-coloured, the last of which is now extinct there. On the botany of Egypt, see Bossier, Flora Orientalis, in progress.

Animals.—The zoology of Egypt is not of remarkable interest, although it contains some very curious points. The absence of jungle and of forest, and the little cover thus afforded to beasts of prey, as well as other wild animals, partly causes this, and we observe few birds of beautiful plumage for the same reason.

One of the most characteristic of the beasts is the camel, which is more at home in the dry climate of Egypt than elsewhere out of his native deserts. It has been remarked, however, that the camel, like his master the Arab,

degenerates when removed into a city or a cultivated tract, that the former commonly becomes mangy, and the latter experiences a physical and moral degradation. The Egyptian camel is of the one-humped kind, which has been erroneously called the dromedary, whereas the dromedary is merely a swift camel standing in the same relation to the ordinary camel that our saddle-horse does to our cart-horse. Camel’s flesh is for the most part eaten only by the peasants and the Arabs of the desert, by the Copts it is considered unlawful food.

It is very remarkable that no representation of the camel has been found in the sculptures and paintings of the Egyptian monuments, among the very numerous figures of the animals of Egypt both tame and wild, and of those brought from foreign lands as presents. It does not appear to have been introduced into other African countries until after the Christian Era (comp Desmoulins, Mém. du l’Institut, 28 juin 1823), but it was known to the Egyptians, although it is by no means certain that it was one of their domestic beasts. Two passages in the Bible which speak of camels in the possession of Pharaohs (Gen. xii. 16; Ex. ix. 3) refer to the time at which foreign tribes had been settled in Egypt; and perhaps the camel was peculiarly the animal of one or all of those tribes, and, as they were hated by the Egyptians, it may have been omitted in the representations of the monuments.

To modern Egypt the camel is very valuable, since the traffic with Syria, Arabia, Western Africa, and Ethiopia is to a great extent carried on by caravans. But the ancient Egyptians appear to have derived their wealth more from tributary presents than from commerce, to have allowed their land commerce to be much in the hands of foreign merchants, like those who brought Joseph into Egypt, and to have left even their sea commerce partly at least to foreigners.

The horse is not known to have been used in Egypt before the time of the Empire. Thenceforward the horses of Egypt were famous, and the armies of the Pharaohs were noted for their war-chariots. From Egypt, Solomon, and in his time the kings of the Hitites and the kings of Syria, had horses and chariots (I K. vi. 28, 29). And long after, when first the kingdom of Egypt was divided, and then that of Judah endeavoured to throw off the yoke of the great kings of the East, and made alliance with Egypt, they put their trust in Pharaoh’s horses (Isa. xxxi. 1). In the representations of battles fought by the kings of the Empire we see no Egyptian cavalry, but only chariots, called “horse” in the inscriptions. At later times they may have had cavalry, properly speaking, of their own, and perhaps at all times among the mercenary or auxiliary forces.

In the present day the horses of Egypt are of a very indifferent breed, and the best that one sees in that country have been brought from Arabia and Syria, but these are seldom of great excellence. It is indeed surprising to find few really good horses in a country bordering on Arabia, and long after, when the Arabian horse was still more remarkable, though not during the existence of the Mamelukes, the finest Arabs, however, are kept in the background by their possessors, partly for fear of the “evil eye,” and partly, in the case of all but the highest dignitaries, to avoid their forcible seizure by those of greater rank and power.

The Egyptian ass holds a middle place between that of Great Britain and the wild ass, which is more swift of foot than the horse. It is tall and handsome, docile, and having excellent pace, particularly a quick and easy amble. Thus it is well suited to the narrow streets of the towns of Egypt, and is therefore commonly used for riding by persons of the middle and lower classes. The mules are
The cattle are short-horned, rather small, and, as of old, very beautiful, speaking artistically. They are exceedingly quiet in disposition, and much valued for agricultural labour by the people, who therefore very rarely slaughter them for meat, and then only for the Franks. Buffaloes of an uncoffined appearance and of a dull black, or reddish-brown colour, strikingly contrasting with the neat cattle, abound in Egypt. When voyaging on the Nile, one often sees them standing or lying in the river by herds. They are very docile, and the little children of the villagers often ride them to or from the river. They are sometimes slaughtered, but their flesh is tough and coarse. Sheep (of which the greatest number are black) and goats are abundant in Egypt, and mutton is the ordinary butcher's meat. Swine are very rarely kept, and then almost wholly for the Franks, the Copts generally abstaining from eating their meat. It appears that the ancient Egyptians, though not forbidden this flesh, rarely ate it, perhaps because it is extremely unwholesome in a hot climate.

The Muslims consider dogs unclean, and therefore those of Cairo and most of the towns are half-wild and without masters, living upon offals, and upon food thrown to them by humans persons. In the villages, however, and particularly in the Thebais, their case is better, for they are kept as guards to protect live stock from thieves, and from hyenas and other wild animals, which come from the deserts by night in quest of prey. The common dog of Egypt is generally of a sandy colour and strong, though not remarkable for courage; but in Upper Egypt, about Thebes, there is a fierce breed of dogs with wiry hair, generally black, and much esteemed for courage by their masters. Cats are as numerous in Cairo as dogs, and many of them are as homeless. They are, however, liked by the natives, who assign as their reason that Mohammad was fond of cats. This may perhaps be regarded as a relic of the veneration in which they were held by the ancient Egyptians. It is not a little curious, that there is at Cairo a royal foundation for the support of destitute cats. The author of this charity was the famous Meenlook sultan, Ed-Dabhir Beyhur, whose humane intentions have of late years been sadly neglected by the trustees.

The wolf, fox, jackal, and hyena chiefly inhabit the deserts and waste places of Egypt, and lurk in the ancient tombs and deserted quarries. The wild cat is also found in that country, though it is not common. The weasel abounds in Cairo, and is proverbial for its mischievous and revengeful disposition, and rats and mice are not among the least of the plagues. The hoopoe, jorzus, hare, and hyrax are likewise natives of Egypt or its deserts, and the tame rabbit is kept for food.

The beasts of the chase of the Egyptian deserts are antelopes of various kinds, and the wild ass, esteemed by the Arabs and Persians to be the prince of game, which is found in the southern part of the Eastern Desert. The most beautiful of the antelopes is the gazelle, which is often tamed and kept in the large courts of the houses of Cairo. In Lower Egypt, principally in the desolate marques near the Mediterranean, the wild boar is found and occasionally hunted. It is, however, a timid animal, so that the sport is not, like boar-hunting elsewhere, exciting and dangerous.

From the representations in the tombs we see that in old times the hippopotamus was one of the wild beasts of the country. It has now retreated above the First Cataract, the southern boundary of Egypt. The crocodile has retreated in the same manner, and instead of being found throughout the Nile in Egypt, is rarely seen even in Lower Nubia. The name of the island of Elphanta, situated a little to the north of the First Cataract, bearing the same signification in hieroglyphics as in Greek, makes it probable that at some remote period elephants were found in Upper Egypt, though now they are not seen north of Abyssinia.

In exploring the tombs and dark parts of the temples the traveller is annoyed by crowds of bats, which extinguish his candle, fly into his face, and cling to his clothes, sometimes rendering examination impossible without a lantern. One species is very large, but the common one is small.

Birds of prey are numerous in Egypt, and of many kinds. Of the most remarkable are three species of large naked-necked vultures—the Arabian, the sociable, and the fulvous; as well as the smaller species called the aquatic vulture. The aquatic vulture has a feathered neck, and when standing is by no means a handsome bird, but it is much to be admired when on the wing from the contrast of the black and white of its plumage, and the steady manner in which it soars in circles. Perhaps the bearded vulture breeds in the most lofty parts of the desolate mountains of the Eastern Desert; for when the French army was in Egypt, one of these birds was killed. It is said to have been of extraordinary size, measuring more than 14 Parsee feet, or more than 15 English, from point to point of its expanded wings. Several species of eagles and falcons, two kinds of hawks, the common buzzard, and the moor-harrier live in Egypt, or visit that country, according as they are migratory, erratic, or sedentary. The common kite abounds at Cairo, and is one of the chief scavengers of the city, the others being the crow, the aquatic vulture, the half-wild dog, and the cat. The ruins and tombs of Egypt, and the modern houses, scarcely ever in perfect repair, shelter owls of various kinds.

The Spanish sparrow, which differs little from that of Britain, the wader-wagtail, linnets, and larks are among the birds of Egypt. The kind of kingfisher which is commonly seen on the Nile, perched on some eminence, and darting suddenly to seize a fish, is very inferior in its plumage, which is speckled, black and white, to the common kingfisher, which is also occasionally seen. The beautiful hoopoe is among the least rare birds, and there are also three species of bee-eaters. The hoopoe may be often seen in Cairo, where it is regarded with some reverence, as the bird of Solomon. Crows of the kind which we call the Rostam crow are very numerous at Cairo. Birds of the swallow tribe, the wood pecker, and the cuckoo are also known in Egypt.

In the metropolis, in the towns and villages, and in the fields, no bird is more common than the pigeon, tame or wild. Pigeon-fancying is a favourite amusement of all classes at Cairo, and in the villages the pigeon-houses are often lofter than the huts upon which they are raised. Tourists on the Nile inflict great loss on the poor peasantry by recklessly shooting these tame birds. Wild turtle-doves build in the courts of the houses of the capital. These courts often serve for the purpose of poultry-yards, in which fowls wander about without any care being taken of them, except that food is occasionally thrown to them. They are consequently meagre, and produce very small eggs. Turkeys, ducks, and geese are kept in the same manner.

Quails migrate to Egypt in great numbers; and sand-grouse, called by the natives kats, from their cry, are common in the deserts. There also the Arabs, like the ancient Egyptians, hunt the ostrich. A red-legged partridge is likewise found in Egypt.

The islands of the Niles, the sand-banks which appear when the river is low, the lakes and marshes, the sheets
of water caused by the inundation, and the mountains near
the river, are the favourite resorts of many kinds of wading
and of web-footed birds.

Of the waders the most interesting would be the sacred
bird of Egypt, if that bird be now found there. But it does
not appear certain that only one species was anciently held
sacred, and if so that this is the ibis religiosus of Cuvier
now known in Egypt. The Egyptian plover is famous on
account of the story, which modern observation has con­
formed, related by Herodotus respecting it and the croco­
diles which accompany it. Of these the most common waders are the spur-winged
plover, the snow-white egret, which has been erroneously
called the ibis, and the pelican. The cormorant, too, is often
seen, as are wild geese and ducks, both of several kinds.

Of the many reptiles the crocodile occupies the first
place. It is seldom observed in the present day in Upper
Egypt. Some years ago it was usual south of Asyut
to see several crocodiles basking in the sun in the heat
of the day on a sand-bank, at the approach of a boat
they would quickly plunge into the stream. They rarely
attack a human being, but it is usual to bathe in the
river, at places where they are reputed to be fierce, and
to bathe at any distance from a boat in the part of
Upper Egypt where they are found. It is said that the crocodile’s
common mode of attacking a person on shore, who is near
the river’s edge, is to approach stealthily and sweep him
into the stream by a blow of his tail, the great weapon of
all the lizard tribe. The smaller saurians are found in
great numbers: of these a species of chameleon may be
mentioned.

Serpents and snakes are among the most common
reptiles, and are of various kinds, including the deadly
cobra and cobra di capello. The house snakes, however,
which are numerous at Cairo, are harmless.

Fish abound in the Nile and in the Lake Menzaleh.
The modern inhabitants of the country are partial to fish
as food, but they say that only those fishes which have
scales are wholesome. The fishes of the Nile are generally
insipid in comparison to those of the sea; though a few of
them, particularly the bultee (Lobius nileoticus, Linn.),
the kush (Percia niloticus), and the bimne (Cyprinus bimne,
Arct.), are of a delicate flavour.

One of the commonest insects is the dangerous scorpion.
Its sting is very painful, and, if no remedy is applied,
sometimes fatal, particularly if a person is stung in the
heel. Large spiders are abundant, including more than
one species of solpugus, incorrectly called tarantulas by
the Europeans, and believed by the natives to be very
venomous, but this is most likely an error. Egypt has ever
been famous for what may be termed insect plagues, but
not to the extent that has been asserted by some
travellers. Caution will enable one partially to escape the
attacks of fleas and bugs, and altogether to avoid the
more dreaded insect usually spoken of with them.

Bees are kept in Egypt, and their honey is much prized
by the inhabitants, who usually eat it in a clarified state.

Bees are kept in Egypt, and their honey is much prized
by the inhabitants, who usually eat it in a clarified state.
It is inferior to that of England, and also to the famous
Greek honey. Butterflies and moths of many kinds are
observed in the fields. There are plantations of mulberry
trees in the eastern part of Lower Egypt, for the rearing of
silkworms. The manufacture of silks was a Government
monopoly, but has lately ceased to be so. The silks of
Egypt are generally inferior to those of Syria and other
Eastern countries, though some have been produced of
great excellence. Among the other insects may be men­tioned the common fly, rightly deserving a place among
the plagues of Egypt, as also the mosquito, which, how­
ever, is not found throughout the country.

Ancient Inhabitants.—In the following remarks on the
ancient Egyptians great assistance has been derived from the
valuable work of Sir Gardner Wilkinson on their
Manners and Customs, which has made us better acquainted
with them than we are with any other people of antiquity.
From the representations of their monuments, and from
the nummules which have been unrolled, we can form
an accurate idea of the personal characteristics of the
ancient Egyptians. In consequence of a misconception
of a passage in Herodotus (iv. 69), and confused notions
respecting the inhabitants of Africa, it has been often sup­
posed that the Egyptians were very nearly allied to the
gnito race. A careful examination of the most distinct
data in our possession has, however, produced a far different
result, and it is now acknowledged that they were more
related to the Caucasian than to the negro type. It has
also been shown that most of the modern inhabitants have
preserved many of the characteristics of their ancient
predecessors, and that it is, therefore, erroneous to suppose
that they are chiefly of Arab origin, although the internes­
ture of Arab blood has so much changed the national
type that it would not be safe to describe the earlier
people from the appearance of the present. Neverthe­
less, one is often struck, among the remains of ancient
monuments, by the similarity of an early representation to
some one of the natives standing by, placing himself upon
an Arab origin, and repudiating the reproach that he is of
the race of Pharaoh.

Judging from the monuments and mummies, the coun­
tenance of the ancient Egyptians was oval, and narrower
in the case of the men than of the women. The forehead
was small and somewhat receding, but well-shaped; the
eyes large, long, and generally black; the nose rather
long, and with a slight bridge, the mouth expressive, with
rather full lips, and white and regular teeth, the
chin small and round, and the cheek-bones a little prominent.
The hair was long, full, curly, somewhat harsh, and almost
always black. The beard was worn in so artificial a mode
that one cannot judge whether it was full or not. The
skin of the men was dark brown; that of the women
varied from olive to pinkish colour in different persons.

The colour of the women was natural, and the darker hue
of the men the result of exposure to the sun, and the
scantiness of their clothing explains why their faces were
not darker than the rest of their bodies.

The dress of the ancient Egyptians did not much vary
at different periods. Under Dynasty IV. it was, however,
simpler than under the Empire. As most monuments re­
mained of the Empire, the dress of the inhabitants at that
time will be described, and this description will apply, in
its main particulars, to the earlier and later times of their
ancient history.

The men of all classes either had shaven heads, with
skull-caps, or wore their own hair, or wigs, very full, and
in numerous plaits or curls, falling to the shoulders, but
sometimes much shorter and in the form of a bag; there

A little spearmint, made into a paste with water and applied
externally to the place stung, has produced, in the many instances in
which the writer has known it used, almost instant relief.
is, indeed, reason to suppose that the practice of shaving the head was universal, except among the soldiers. All the hair of the face was also shaved, except in the case of kings and great persons, who had a small formal beard, possibly artificial, beneath the chin.

The king was distinguished from his subjects by the richness of his apparel. His head-dress was sometimes his own hair, or the wig, alone; and at others he wore the high crowns of th and Lower Egypt, the former being a kind of conical helmet, and the latter a short cap with a tall point behind, worn outside the other. He is also occasionally represented with another form of high cap. The figure of an asp, the emblem of royalty, is often tied just above his forehead. His beard was about three inches long, and one inch broad and deep, and formally planted.

The simplest royal dress was a kilt, usually reaching nearly to the knees, rather full in front, having a girdle above, from which hung before a broad band, richly ornamented, and peculiar to the king, like the lion's tail (natural or artificial) which was attached to it behind, and reached nearly to the ground. Sometimes a large and full skirt was worn over the kilt, descending almost to the ankles, and having wide sleeves reaching to the elbow; this outer dress is occasionally simply a skirt. Both these dresses were usually of white linen, and the outer dress was apparently fine and transparent. Sandals were worn on the feet, and the ornaments were armlets, bracelets, both flat and broad, and deep necklaces.

The ordinary costume of men of the upper and middle classes was the same as that of the king, the short kilt, with sometimes the long skirt or skirt of fine linen above it, tied in various forms. Their beards were very short, scarcely exceeding an inch in length, and of a formal square shape, and they wore the full hair or wig, or a skull-cap. They generally went barefoot, but sometimes used sandals.

The priest was occasionally clad in a leopard's skin, either tied or thrown over the shoulders, or worn as a shawl, the fore-legs forming sleeves. Military persons are often represented with helmets, and sometimes with short coats or corslets of plate-mail. The royal princes were distinguished by a side lock apparently curiously plaited.

The dress of the queen consisted of a tight skirt, the waist, supported by shoulder-straps, and bound nearly to the ankles. It much resembles that of the queen's of kings and great persons, who had a small formal beard, possibly artificial, beneath the chin.

The children of all ranks were very simply dressed, when clad at all, though those of rich persons were sometimes attired as their elders. Boys were distinguished by the side-lock, which the princes, as before mentioned, wore in a peculiar fashion.

Religion.—The credit which the Egyptian priests enjoyed in antiquity for a knowledge of philosophy led to the expectation among modern scholars that, when hieroglyphics were read, the world would recover a lost body of human speculation. The first results disappointed this expectation, but later studies have gone far to justify it. The statement of what those studies have achieved may be divided into two main subjects—the teaching as to the gods and that as to man's duties and destinies, rites and ceremonies coming under both heads.

Had the Egyptians any idea of one God—in other words, is their religion a complex structure raised upon a recognized monotheistic foundation? The Egyptian religious writings are held by M. de Rouge to give an affirmative answer to this question. They speak of one supreme being, self-existent, self-producing, the creator of heaven and earth, called the double god or double being, and the parent of a second manifestation. From the idea of a supreme deity, at once father and mother, producing a second form, probably originated a first trial like the triads of father, mother, and son frequent in Egyptian mythology. To the local divinities the attributes of this supreme deity are given, as though they were mere personifications: that they were originally so is, however, not certain. Ra, the sun, is indeed spoken of as this supreme being, but this appears to have been a later phase of opinion. (De Rouge, "Etudes sur le Rituat Funéraire," Rev. Arch., n.s., l. 356 seqq.) It was probably an attempt to substitute a popular materialistic belief for a philosophical creed. A significant instance of this tendency is perhaps in the endeavour of a king of Dynasty XVIII. to abolish all worship but that of the solar disk—sun-worship in its most material form.

A very ancient moral tract, the papyrus of Ptah-hotep, composed under Dynasty V., although a purely Egyptian work, mentions Osiris and a divinity who may be a form of Osiris, yet speaks constantly of God as if the author had the idea of one God.

It also appears from one remarkable fact that this idea prevailed in Egypt before the conversion of the nation to Christianity. The Copts took care to eliminate from their vocabulary all the words connected with the religion of their forefathers, substituting for them Greek equivalents. Their term for God is, however, not Greek but Egyptian, NOY;[1], the hieroglyphic neter. They also used it for heathen objects of worship, god or goddess. These uses must therefore have been prevalent in the vulgar dialect when it was first written in Coptic.

Though it cannot reasonably be doubted that the Egyptians had a distinct idea of monotheism, this idea was mixed up with the basest polytheism. The double character which we perceive in the race and the language, both partly Nigritian, partly Semitic, is equally evident in the religion. Every town in Egypt had its sacred

animal, or fetish, and every town its local divinities. As the animal worship was associated with higher ideas by the union of an animal's head with the body of a man in the figures of divinities, so the local divinities were connected with the monothestic idea by intermediate forms, principally identifying them with Ra, who thus was the generally received form of the notion of one god. According to this view monotheism was not the parent of polytheism, but in a later phase connected with it.

Another great change affected the essential ideas of the Egyptian religion. For many centuries Seth, specially the divinity of Lower Egypt, who seems to have represented then, as certainly afterwards, the destructive power of nature, held a place in the Pantheon, although regarded as the adversary of Osiris and thus of mankind, whom, however, he finally befriended. He seems thus to have had a character of necessary evil. At length, after the Empire, he was expelled from the Pantheon. This may have been because the worship of Seth was repugnant to a reign whose house of Asiatic origin, which might have held the Pantheon which identified physical and moral evil. It may have been because Seth had been considered to be the divinity of the eastern neighbours of Egypt, and with their success and the fall of Egyptian supremacy had come to be thought hostile to that country. If this were the case, the kings who proscribed his worship could have had no relation to the notions supposed to reverence Seth. In effect the change identified physical and moral evil and destroyed the earlier philosophical notions on the subject, besides introducing some confusion into the theanthropic speeches of orders of gods. Manetho of divine dynasties. The explanation is to be found in the worship of each town of a cycle of gods. This cycle is called "the society of the gods," or "the nine gods." M. de Rouge does not admit the second rendering except as a plural of excellence ("Études," Rev. Arch., i., p. 237). The number varies at different places and in different lists at the same place, but is always nearly or exactly nine. The Egyptians themselves explained this cycle as the self-development of Ra; the other gods were in the view of his tributes (De Rougé, l.c. 236, 237, Râ. xvn. 2, 3). Two orns of the cycles acquired the highest importance as representing the systems of the learned men of Memphis and Thebes, the successive great capitals of Egypt. The two systems are thus given by Professor Lepsius:

MEMPHITE SYSTEM.

1. Ptah (Phô, Ἱππος). II. Amon (Ἀμών, Zôs). III. Mentu (Μεντ.)
IV. Shu (Σου). V. Nut (Νατ).
Shu (Σου; Διδώνω), and (6.) Isis (Ἱσ, Διάσφαρη), and (7.) Set (Σέτ, Τούφ), and (8.) Har (Χάρ, Ἀρεάλω), and
Hat-har (Ἀρεάλ, Ἀρεάλω).

THESAuran SYSTEM.

IV. Shu (Σου). V. Tefnet (Τεφνῶ).

The views of Professor Lepsius on the origin and constitution of these systems, with such modifications as later researches have suggested, may now be given. We first observe that the two systems are but variants, and may be treated as one. They consist of male divinities, most of whom are associated with goddesses. These goddesses hold an inferior place, and are not to be counted in reckoning the number of the order, except perhaps Isis, whose importance is much greater than that of the others. An examination of the various forms of the two systems immediately suggests that they increased in course of time, Ptah and Amen, the chief gods of Memphis and Thebes, having been added for state reasons. The order thus reduced consists of two groups, the group of Ra, and that of Osiris. The group of Ra is wholly of solar gods, the group of Osiris begins with Seb and ends with Hathor. Sebek then stands alone, but he is wanting in the older lists, and is only an addition of the Theban system.

The solar group consists of Ra, or else Mentu and Atum, and Shu Mentu and Atum are merely a division of Ra into his two chief phases, the rising and the setting sun, the sun of the upper and of the lower world. Both are solar divinities (Brugsch, Géogr. Inscr., i. 254.), the solar light, is the son of Ra or of Mentu or Atum, Tefnet, the goddess associated with him, is the daughter of Ra.

The Osiris group is not genealogically connected with the solar gods. The central point of the group is found in Osiris, with his consort Isis and his opponent Sêb. Seb and Nut are merely extensions of the group upwards. They are, however, spoken of as parents of the gods, showing that they represent the commencement of a series Osiris, Isis, Seth, and Nephthys were usually considered their children, and Horus, the child of Osiris and Isis. Hathor is associated with Horus, but her genealogical place is not clear. It is, however, certain that she is of the family of Osiris. The characteristics of this group are predominantly cosmic, this is true of the myth of Osiris, and consequently of the whole group, and is especially evident in the cases of Osiris and Isis, Seth, and Seb and Nut.

How did these two groups come to be united in a single series? Professor Lepsius argues that this was due to the influence of Thamus, the oldest Egyptian royal seat, from which the first historic king Menes came to Lower Egypt and founded Memphis. Thamus at a very early time merged into the more famous Abydos. Abydos was the great seat of the worship of Osiris, which spread all over Egypt, establishing itself in a remarkable manner at Memphis. All the mysteries of the Egyptians and their whole doctrine of the future state attach themselves to this worship. Osiris was identified with the sun, and the union of the two groups was thus not forced. Both had indeed a common origin. Sun-worship was the primitive form of the Egyptian religion, perhaps even pre-Egyptian. The first development was the myth of Osiris, due to the importance of Thamus, just as the rise of Memphis put Ptah, an abstract idea of intellectual power, even before Ra. So the rise of Thebes introduced Amen, who was identified in the form Amanus with Ra, and as an intellectual principle placed before the physical solar powers. This argument derives great weight from the relative position given to the two groups, the solar divinities coming first, and from the circumstance that the religious reform under Dynasty XVIII. suppressed everything but material worship, as though this had been the primitive belief of Egypt. 3 M. de Rougé, in his examination of the Egyptian Ritual, comes to a similar but more definite result in treating

---

1 These have been called the systems of Memphis and Thebes. The solar cycle of Memphis was, however, not the system of Manetho which has been called Memphis, and has a distinct local character (Brugsch, Géogr. Inscr., i. p. 237).

2 Shu, true spelling since discovered, is here put for Μα.

3 See Lepsius, Uber den ersten ägyptischen Göterzweck und seine geschichtlich-mythologische Entstehung" Ber. Akad., 1851.
of the mythological elements of the important seventeenth century. He traces the solar gods to Helopoli, and considers the Osiris myth as probably derived from Aybodis, and added at a later time. Professor Lepusus does not admit the Helopoliapolis as of the solar group of the Osiris myth and political importance of Helopolis. Yet the circumstances that the chief divinities of that city, which had the sacred name Pe-ram, the abode of Ra, were Atum, Shu, and Tefnet (Rel. xvii. 4, Ap. Dragash, Geogr. Inscr., i. 254, cf. 265) seems to conclude.

Some account may now be given of these divinities in the order of the lists, the later additions being noticed last and then lesser divinities. It will be impossible to give more than the simpler particulars, and many names in the Pantheon must be omitted altogether.

Ra, the sun, is usually represented as a hawk-headed man, occasionally being represented on his solar disk, round which the uraeus, symbol of royal power, is sometimes coiled. His symbol is either the solar disk or the hawk. Ra held a most ancient and Egyptian divinity, except Osiris. The worship of Osiris under his own name was more common than that of Ra under his, but this was in some degree compensated for by the union of Ra with other gods under solar names, such as Amen, Num, Seked, forming the composite divinities of Amen-ram, Num-ra, Seked-ram (Lepusus, Rel. Aeg. Gg. Geter., i. 356). In the religious paintings he is the supreme being, carrying on his course a constant warfare with evil, and triumphing over evil, represented by the great serpent Apopis, a wholly evil being, not a divinity. His career resembles that of Osiris, but with notable differences. Ra is purely solar. He is nearly associated with any concept, and so the sacred pens are called a female Ra (Lepusus, Rel. Aeg. Gg. Geter., i. 325). He is always victorious. He protects mankind, but has nothing in common with them. Osiris on the other hand is only solar because he is the beneficent power of nature. He is constantly associated with Isis. He has a life-long conflict with a malignant power, his brother or son Seth, who is not wholly evil. Vasequesh and killed he receives his life and wins, but it is rather Horus his son who wins, and Horus, a sun-god, is the direct link with Ra in the Osiris family. Osiris protects mankind because his life resembles theirs. If he did not live on earth, at least his tomb was shown there. At Helopolis two animals sacred to Ra hesitated, the black ibis, the emblem of Osiris, and to Ra, Atum, and the Phaemon (Bennu) sacred to Ra. Both are connected with Osiris, the bull by the worship of Apis at Helopolis, the Phoenix by the representation of Osiris as the Bennu. In ch. xvi. 227, 225. In addition the sacred Phoenix was reverenced at Helopolis.

In the attempt under Dynasty XVIII. to establish sun-worship in an original or ideal simplicity, the only representation is the solar disk with the uraeus entwined round it, and rays ending in human heads, one of which holds the symbol of life to the worshipper. The great sun-temple then founded no status whatever (Lepusus, Rel. Aeg. Gg. Geter.).

Meniu and Atum may best be noticed together as merely two phases of Ra, representing, as already stated, the rising and the setting sun, the sun of the upper and the lower world. Their twin-character is seen in the circumstances that Meniu was worshiped at Southern Am (Hermouthis) and Atum at Northern Am (Helopolis, the On of the Bible). Meniu, or Menf-ta, is represented as Ra with the head of a hawk, as Atum in a human form. Atum and Meniu cannot be distinguished from Ra except that probably their attributes were more restricted, and Meniu seems to have been limited to what the human form of Atum may perhaps have a relation to Osiris 9.

Shu is, however, not mentioned among the divinities of Helopolis in the great Papyrus of Harnes III. Records of the Psa., vs. 35 seqq.

9 In the 17th chapter of the Ritual the justified dead is called in his new condition Tm, equivalent to Atum. This may be merely

because the word Tm has the same meaning, and may be thus a play upon the name of the divinity (of De Rouge, "Etudes," 350, 351), but it is likely that Tm is here used as Osiris everywhere to indicate the divine quality of the justified.

the sun; as Amen-ra ba-nun-‘t, “the husband of his mother,” he
takes his name from Min in Kahun, the goddess of the mother principle. Ramses
II. has the ram-headed form that Greek notions would lead us to expect.

From this the crocodile-headed god, seems to have held a similar place
to that of Min in the Fourth Dynasty. He was at once the guardian of the
monuments of Upper Egypt, and the
Thoth, or Taus, is the head of the second cycle in the two
principal forms of the cycles. As the chief moon-god he thus
takes an inferior place corresponding to that of Ba. He is
generally represented as this-headed, and frequently bears the disc
and crescent of the moon. He is the god of letters and of the
ancient Egyptian thesaurus, where the name Sesennu, also
Sebeus, is found, and to which place. Thoth is called his patron god (Lepsius,
1. 220), but she is not his consort at Hermopolis (Brugsch,

Nelth, or Nit, worshipped at Saos, identified by the Greeks with
Athens, is one of the few goddesses who held the first place in local
worship. From the idea of a supreme being, single and self-
present, as the aspect of a finite power, it is
private—that of the temples and that of the tombs. Every town had at least one temple dedicated to the chief divinity of the place, with certain associated gods, and usually, if not always, a living symbol in the form of a sacred animal supposed to be animated by the chief local divinity. The services were conducted by priests, and on occasions by the king, and by scribes, who sometimes formed a college and lived at the temples, the various duties of which required the services of learned men. It is probable that the common people had a very small share in the religious services, the most important of which took place in the smaller inner chambers, which could never have admitted many worshippers. The outer courts, and still more the great inclosures containing the whole group of temple-buildings, must, however, have been the chief public resort for business and pleasure. There were no other public buildings, or, apparently, market-places. Like the modern mosque, the temple must have been the chief centre of the population.

The worship in the tombs was not local. It was always connected with Osiris or a divinity of the same group, and had the intention of securing benefits for the deceased in the future state. It took place in the chapel of each tomb of the wedy; and though properly the function of the family, whose members officiated, the inscriptions invite all passers-by; as they ascend or descend the Nile, overlooked by the sepulchral grottos, to say a prayer for the welfare of the chief person there buried.

The sacrifices were of animals and vegetables, with libations of wine, and burning of incense. Human sacrifice seems to have been practised in early periods. The monuments do not mention it, but Manetho speaks of its having been abolished, at least at one place, by Amosis, no doubt the first king of Dynasty XVIII. The reference is probably to some barbarous usage during the great war with the Shepherds.

The origin and destiny of man in the Egyptian religion is now known to us on the authority of its own documents, which in the main confirm what Greek writers had already stated on the subject. The aspect of the Egyptian teaching is either that of a simple theory, which was afterwards mythically interpreted, or of a union of such a theory with a superstition existing side by side with it. In the famous seventeenth chapter of the Ritual it is possible, as De Rongé has done with extraordinary skill, to extract from the text a consistent theory which the glosses confuse by the mythological turn they give to the simple statements of the Ritual. Not only is it sufficiently clear that the Egyptians attributed to the human soul a divine origin, that they held that it was throughout life engaged in the warfare of good and evil, and that after life its final state was determined by judgment according to its doings on earth. Those who were justified before Osiris passed into perpetual happiness, those who were condemned into perpetual misery. The justified took the name of Osiris, the judge, under which they indeed already appeared for judgment.

It had this plan outline been left unfilled by the priests, the Egyptians might have been credited with a lofty philosophy. Unfortunately, however, a thousand superstitions took the place of the attempt to lead an honest life. In the tombs we find every one who could pay for a sculptured record characterized as justified, every mummy already an Osiris. How was this determined? Possibly there was a council held, which decided that the deceased could be treated as one who was certain of future happiness. It is, however, more probable that the learning certain prayers and incantations, the performance of ceremonies, and the whole process of embalming, together with the charms attached to the mummy, and prayers said by those who venerated the tomb, were held to secure future happiness. In reading the Ritual we are struck by the small space given to man's duties as compared with that filled by incantations and charms. The human mind must have lost sight of the value of good and seized upon the multifarious equivalents which needed nothing to be done by way of either self-restraint from evil or active benevolence. Thus as we look at the documents we see a noble idea lost in a crowd of superstitious fancies, as we look at the Egyptians as they lived, we trace the effect of the undomesticable good, and yet find it always greatly alloyed with evil. The Egyptian idea of the future state is the converse of that of Socrates. It is no little incident of human weakness, like the request to sacrifice a cock to Asculapius, which seems but does not destroy a harmonious whole, a mere glimpse of truth is seen through thick mists peopled with the phantoms of the basest superstition.

In the long course of ages the Egyptian ideas as to the future state seem to have undergone changes, not in themselves, but in the manner in which they were regarded. The vast labour expended on the Pyramids, and their solid simplicity, are in striking contrast with the elaborate religious representations of the tombs of the kings of Dynasties XIX. and XX. So, too, the sculptures on the walls of the tombs of subjects of the earlier kings, representing the everyday life of duty and pleasure, give place to funeral and religious scenes in the later periods. Those were fashions, but they show the changed mood of the national mind. It is only in a tablet of the age of the Poiremes that Greek ideas assert their predominance in a touching lament addressed from the land of shades, which no longer speaks of active happiness, but in its place of purposeless oblivion (Birch, "Two Tablets of the Poireme Period," Archéologiques, xxxix. 22, 23). Laws and Government.—We are gradually gaining an insight into the Egyptian laws. This is principally due to M. Chabas, the third volume of whose Mélanges Égyptologiques mainly consists of essays, nearly all by himself, on texts relative to the administration of justice under the Pharaohs. His general results confirm the accuracy of what Diodorus Siculus and Plutarch state on the subject. It was to be expected that their evidence would have been good as to matters which could not have been easily misunderstood, and which must in the case of Diodorus have been personally observed. In this matter the two acts of authority may fairly be combined.

The government of Egypt was monarchical. It was determined as early as the rule of Dynasty II., according to Manetho, that women could reign. Accordingly we find instances of queens regnant. Their rule, however, seems to have been disliked, and they are passed over in the lists made under Dynasty XIX., when, it may be observed, the royal family seems to have been affected by Semitic influences. The royal power can scarcely have been despotic, although under certain kings it became so. It is sufficient to compare Assyrian and Babylonian with Egyptian history and documents to perceive the difference. The earliest monuments indicate a powerful local aristocracy holding hereditary functions. Those of
the Empire (Dynasties XVIII.-XX.) scarcely indicate any such class. Even the princes are no longer a royal clan, but the children of the reigning sovereign. The whole system of government rests with the king, who appoints all the functionaries and dismisses them at his pleasure. Hence arose a vast and corrupt bureaucracy; to which the decay of Egypt may have been mainly due. At all times the country was governed by nomarchs and lesser officers.

In the earliest period these were local magnates whose office was at least sometimes hereditary, and whose interest it was to promote the welfare of their districts. Under the Empire governments seem to have been mere places of profit given by favour and held by force and corruption, according to the Turkish method.

The laws were administered by judges appointed by the king. It is certain that commissions for an occasion were thus formed. We do not know that there were judges appointed for life; but it is probable that such was the case, as it must have been the duty of a class to be thoroughly acquainted with the written laws. A legal scribe may, however, have been attached to each commission.

All the particulars of each case, though not necessarily submitted in writing, were recorded, and the decision was written. The process was conducted with great care, and the culprit examined on oath. The punishments probably were not extremely severe. For murder, but not for manslaughter, death was the penalty. Adultery was severely punished, perhaps rather by custom than by law. Theft was rigorously prosecuted. For sacrilegious theft the criminal was punished with death. The laws relating to debts are not yet well known. They appear to have been complicated by a system of loans and pawning, and to have been subject to modifications. Of the tenure of land we know little.

The temple-lands seem to have been held at will, as it must have been the duty of each charioteer, and this was especially the case of those men who knew little but much of its use. There are other indications of the social condition of Egypt under the Empire in the complaints of the lower classes; and even the brigandage to which they were subject on the borders of Syria is at once accounted for.

The women were not secluded, but they lived in the cities. The Egyptian troops seem to have been attached to each family. The women were not secluded, and they may have been entertained by the company, and often at the time of marriage. The women were not secluded, but they lived in the cities. The Egyptian troops seem to have been attached to each family. The women were not secluded, and they may have been entertained by the company, and often at the time of marriage. The women were not secluded, but they lived in the cities. The Egyptian troops seem to have been attached to each family. The women were not secluded, and they may have been entertained by the company, and often at the time of marriage. The women were not secluded, but they lived in the cities.
These two kinds of entertainment are precisely what are customary at the present day in Egypt. Among the amusements of the ancient Egyptians was witnessing the performance of various gymnastic feats. They had several games, one of which probably resembled draughts. Under the old kingdom the chief occupations of the rich seem to have been those of a country life, in its duties, the superintendence of the herds of sheep, of the harem and of horses, and of the shipment of produce, and the examination of fisheries, or again in seeing to the efficient work of the people of the estate who were engaged in any craft, and the pleasures of country life filled up the leisure. In ancient times Egypt had far more cover for wild fowl than now. Thus we see from the subjects of the tombs that the rich Egyptian was, in the habit of going into the marshes in a canoe, generally with some of his children, to spear the hippopotamus, or more frequently to knock down birds with the curved throw stick. In fishing, a cat was sometimes used as a retriever. At other times he fished in his ponds, or shot or croused with hounds various animals of the water-kind. Every rich man in the age of the Empire had a chariot, generally drawn by two horses, which he usually drove himself, standing up in it. The life of the ladies was not unlike that of the men, except that they only joined in the sports as spectators. They seem to have passed their time in household matters, in vastating, and in the simplest country pleasures. Occasionally they rode in heavy cars drawn by oxen. Their manners appear to have been indolent and luxurious. Among the lower orders the lighter work usually fell to the women. Both men and women led hard lives, having scanty clothing and poor food; yet the genial climate, in which the wants of the labourer must always have been few, rendered their condition not so painful as one might suppose.

Language and Literature.—The language of the people was the Egyptian, the latter form of which, after they had become Christians, is called Coptic. Comparative philology has not yet satisfactorily determined its place. There can be no doubt that it is related to the Semitic family, but it has not yet been proved to belong to it. The grammatical structure is distinctly Semitic, and many roots are of the type to the Semitic languages. On the other hand, the Egyptian has essential characteristics which detach it from this family. It is monosyllabic, and its monosyllabism is not from which scholars have endeavoured to deduce Semitic, but rather such as would belong to any degraded condition. The monosyllabism is like that of Sumerian. Dr Brugsch strongly affirms the affinity of the Egyptian to the Indo-Germanic as well as the Semitic languages (Histoire, 2 ed. 6), but the former relation has to be proved. It has been supposed that the monosyllabism of the Egyptian is due to its having in part originated from a Nigrum source (Genesis of the Earth and of Man, 2d ed. 255, seqq.). Certainly this is a characteristic of some Nigrum languages, and the want of any large agreement in the vocabulary would be sufficiently explained by the changes that the languages of savage nations undergo from the absence of a literature. It can therefore scarcely be asserted with Dr Brugsch that the Egyptian has no analogy to the African languages (loc. cit., which, no doubt, he intends those which have no Semitic element. The problem will probably be solved either by a careful study of all the African languages which show traces of Semitic structure side by side with those that are without such traces, or by the discovery of the unknown element in Egyptian in the Akkadian or some other primitive language of Western Asia, which cannot be called Semitic in the recognized sense of the term. During its long history the language underwent little change, until it became Coptic. It had two dialects—those of Upper and Lower Egypt, (Brugsch, ubi dict); and by degrees a vulgar dialect was formed which ultimately became the national language not long before the formation of Coptic. One curious innovation in the Egyptian language was the fashion under the Ramses family of introducing Semitic words into that of Egyptian ones. From the manner in which these words are spelt it is evident that the Egyptians at that time had no idea of a Semitic element in Egyptian, for they always treat them as foreign words and retain the long foreign forms. The chief change in Coptic was the introduction of many Greek words, especially to supply the place of religious terms eliminated from the vocabulary. The inscribed and written character of Egyptian was the hieroglyphic, a very complex system, which expressed ideas by symbols or by phonetic signs, syllabic and alphabetic, or else by a combination of the two methods. From this was formed the hieratic, a running hand, or common written form of the hieroglyphic, principally used for documents written on papyrus. Its oldest records are not equal in age to the Curvin line (hieroglyphic inscriptions), but probably it is not much later in origin. The demotic or cursive writing is merely a form of hieratic used for the vulgar dialect, and employed for legal documents from the time of Dyn. XXVII. downwards. The Coptic is written with the Greek alphabet, with the addition of six new letters and a ligature, these letters being taken from the demotic to express sounds unknown to Greek. For further details see the article Hieroglyphics.

Much ancient Egyptian literature has come down to us, and it must be allowed that from a literary point of view it has disappointed expectation. What it tells us full of interest, but the mode of telling rarely rises to the dignity of style. So unsystematic is this literature that it has not given us the connected history of a single reign, or a really intelligible account of a single campaign. The religious documents are still less orderly than the historical. It is only by the severe work of some of the ablest critics during the last fifty years that from those disjunct materials a consistent whole has been constructed.

The most important religious work is the Funerary Ritual, or Book of the Dead, a collection of prayers of a magical character referring to the future condition of the disembodied soul, which has already been noticed. It has been published by Dr Lepsius (Das Totenbuch der Aegypter) and M. de Rougé (Rituel Funéreaire), and translated by Dr Birch (Bunsen's Egypt's Place, v.); de Rougé, in his most interesting papers in the Revue Archéologique (n s.), has done the utmost that a splendid critical faculty and an unusual mastery of language could achieve to present parts of the work in the most favourable form. Still it must remain a marvel of confusion and poverty of thought. Similar to the Ritual is the Book of the Lower Hemisphere. The other religious works and inscriptions are of a wider range. The temple inscriptions indeed are singularly stilted and wanting in variety; but the papyri contain some hymns which are of a finer style, particularly that to the Nile by Enea, translated by Canon Cook (Records of the Past, 107), and that to Hathor, translated by Dr Lushington (ibid. viii. 129) and Professor Maspero (Histoire Ancienne, 33, seqq.). The moral writings have a higher quality than the religious, if we may judge from their beauty remains. The historical writings fall into two classes according to their official or unofficial character. Those that are official present the worst form of the panegyric style, the others are simple though wanting in method. The letters are of more interest, from their lively portrayal of ancient Egyptian manners. In works of fiction there is a greater depth of
is not without its merits, but it has that want of lofty ideas and of charm which is characteristic of the literature of nations which have written very much and have had no other means of addressing mankind.

Science.—Fresh information is being constantly required as to the knowledge of science possessed by the ancient Egyptians. Their progress in astronomy is evident from their temples, and still more from the addresses they formed for the adjustment of different reckonings of time. Their knowledge of geometry is attested by their architecture, and by a document on the lands of the temple of Adfoo; and the annual inundation must have made careful surveys and records necessary for the preservation of landed property. Very great mechanical skill must have been needed to move the vast blocks used in their buildings, sometimes for very long distances, in part by difficult land-routes, and then to place them in position. Considering the want of iron, and of any but the very simplest mechanical appliances, the achievements of the Egyptian architects are an enigma to modern science (Brugsch, Hist., 2d ed. 52) Chemistry and metallurgy had also made great progress. The hardening of the bronze tools with which they cut granite is a proof of this, and the manner in which Moses destroyed the golden calf is another evidence. Medicine and surgery were much studied, and the Egyptians were in those sciences only inferior to the Greeks.

Arts.—Of the arts architecture claims the first place, sculpture and painting being subservient to it among the Egyptians. Temples were not built to contain statues, but to be to the ideal, but their character does not seem to have been produced had the art been more advanced, in some instances it excels their modern inhabitants have preserved its tradition. It may therefore be mentioned that they are ignorant of harmony, but have fineness of ear and of execution. The musicians often sang or danced while they played. The dances of both men and girls were of various kinds, from what may be called feats of agility to slow movements. The dancers were chiefly girls, whose performances evidently resembled those of their modern successors, and whose clothing was even more transparent or scanty. The Egyptians had a great variety of musical instruments, the number of which shows how much attention was paid to the art. Various kinds of harps are represented, played with the hand, and of lyres, played with or without the plectrum, and also a guitar. There are other stringed instruments, for which it is difficult to find a modern name. The Egyptians had also flutes, single and double pipes, the tambourine of various forms, cymbals, cylindrical maces, drums of different kinds beaten with the hands or sticks, the trumpet, and the sacred sistrum. The military music was that of the trumpet, drum, and cylindrical maces; but almost all the instruments were used in the temple services. It is impossible to form any conjecture as to the character of the music, unless we may suppose that with many of the old instruments the modern inhabitants have preserved its tradition. It may therefore be mentioned that they are ignorant of harmony, but have fineness of ear and of execution. The musicians often sang or danced while they played. The dances of both men and girls were of various kinds, from what may be called feats of agility to slow movements. The dancers were chiefly girls, whose performances evidently resembled those of their modern successors, and whose clothing was even more transparent or scanty. Ceremonies.—We know little of the private festivities of the ancient Egyptians. In particular no representation of a marriage ceremony has yet been discovered on the monuments. The greatest ceremony of each man’s life was the construction of his tomb, and the costly personal event was the funeral, the Egyptians were singularly methodical, delighting in music and the dance, and so given to caricature that even in the representation of a funeral ceremony the artist cannot omit a ludicrous incident. The double origin of the race seems as apparent here as in their physical type and their religion. The generous qualities of the Shemite are being perverted by the inferior impulses of the Nigritan; and again the bright elements of the Nigritan character are strangely darkened by the shadow of the gloomy tendency of the Shemite.

The industrial arts were carried to a high degree of excellence by the ancient Egyptians. In weaving and all the process as connected with the manufacture of linen they have never been surpassed. Their pottery was excellent in quality and suitable to its various purposes, and their glass but slightly inferior to that of the Greeks. In the making of furniture, and instruments of music, vases of deceased, alabaster, and other materials, arms and domestic implements, they showed great taste and skill, and their influence on Greek art through the Phcenicians is undoubtedly, though they did little more than afford suggestions to more skilful artists of Hellas.

The dancers were chiefly girls, whose performances evidently resembled those of their modern successors, and whose clothing was even more transparent or scanty.

Ceremonies.—We know little of the private festivities of the ancient Egyptians. In particular no representation of a marriage ceremony has yet been discovered on the monuments. The greatest ceremony of each man’s life was his funeral. The period of mourning began at the time of death, and lasted seventy-two days or a shorter time. During this time the body was embalmed and swathed in many linen bandages, the outermost of which was covered with a kind of pasteboard, which represented the body made of metal, in the form we call a mummy, as a labourer in the Elysian fields, carrying the implements of husbandry, the face and hands being alone seen, and the rest of the body being painted with subjects relating to the future state, and bearing a principal inscription giving the name and titles of “the Osiris, justified.” The vases were separately preserved in vases having covers in the forms of the heads of the four genii of Amenti. The mummy was inclosed in a case of wood having the same shape, and this was again inclosed, when the deceased was a rich man, within either another wooden case, or more usually a sarcophagus of stone, sometimes of the same form as the mummy, but generally rectangular, or nearly so. The mummy was then placed on a sledge, drawn by oxen or by men, and was frequently taken
to the bank of the river, or the shore of a sacred lake, which was to be crossed in order to reach the place of burial. A sacred boat carrying the mummy, attended by mourners, was towed by another boat, and followed by others containing mourners, offerings, and all things necessary for the occasion (Amy. Eg., pl. 83-86). On reaching the tomb the sarcoagus was placed in a sepulchral chamber, usually at the bottom of a pit, and offerings for the welfare of the deceased were made in a chapel in the upper part of the tomb. One tomb sufficed for each family, and sometimes for some generations; and in the case of the less wealthy, many were buried in the sepulchral chambers of a single pit, above which was no structure or grotto. It has been already noticed that, according to Diodorus, one eye was judged by a legal tribunal before the right of burial was permitted, and of this there may be a survival in the practice of the modern Egyptians, which prescribes that a witness must answer for the good character of the deceased before his burial (Modern Egyptians, ch. xxvii.). After the burial, offerings were made at stated times each year by the family, and the chief inscription begged the passer-by to say a prayer for the good welfare of the modern Inhabitants.]

[Mr. Lane in 1834 estimated the population of Egypt at less than 2,000,000, and gave the following numbers as nearly those of the several classes of which it is mainly composed, namely:

<table>
<thead>
<tr>
<th>Class</th>
<th>Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Muslims (fellahin or peasants, and townspeople)</td>
<td>1,750,000</td>
</tr>
<tr>
<td>Christian Egyptians (Copts)</td>
<td>150,000</td>
</tr>
<tr>
<td>Circassians, or Turks</td>
<td>10,000</td>
</tr>
<tr>
<td>Syrians</td>
<td>5,000</td>
</tr>
<tr>
<td>Greeks</td>
<td>5,000</td>
</tr>
<tr>
<td>Armenians</td>
<td>2,000</td>
</tr>
<tr>
<td>Jews</td>
<td>6,000</td>
</tr>
</tbody>
</table>

The second group, exclusive of the Arabs of the desert, numbers about 70,000 (Mod. Eg., Introduction). The last official return (1876) estimates the population of the provinces as follows:

- Egypt Proper (Upper, Middle, and Lower) 5,250,000
- Nubia 1,000,000
- Ethiopia 5,000,000
- Darfour, &c. 5,700,000

Of the present population of Egypt, the Muslims constitute seven-eighths, and nearly four-fifths of that of the metropolis; and to this class, and more particularly to the people of Cairo, the following sketch of personal characteristics and customs will relate, save in some few cases, which will be distinguished from the rest. In describing the personal characteristics of this remarkable people, Mr. Lane, in the first chapter of The Manners and Customs of the Modern Egyptians (which was written just before European influence was felt in the country, and still deservedly ranks as the only book of authority on the subject), says:

"In general the Muslim Egyptians attain the height of about 5 feet 8 inches. Most of the children under 9 or 10 years of age have spare limbs and a distended abdomen; but as they grow up their forms rapidly improve. In mature age most of them are remarkably well-proportioned, the men muscular and robust; the women very beautifully formed, and plump, and neither sex is too fat. I have never seen corpulent persons among them, excepting a few in the metropolis and other towns, rendered so by the fatness of the climate. In Cairo, and throughout the northern provinces, those who have not been much exposed to the sun have a yellowish but very clear complexion, and the women, unusually darker and coarser complexion. The people of Middle Egypt are of a more dark brown colour, and those of the more southern provinces are of a deep brown, or brownish black colour. The heads of the Nubas, where the climate is hottest. In general the countenance of the Muslim Egyptians (I have seen many of them of a fine oval form) is composed of the following features: a finely shaded countenance, though some indicating sadness, and a beautifying expression—eyes more beautiful can hardly be conceived. Their charming effect as much heightened by the concealment of the features from the sun, which is as that of other races is covered by a turban, and is rendered still more striking by a uniform appearance among the females of the higher and middle classes, and very common among those of the lower orders, which is so closely fitted as to hide all the face, and, with the exception of the eye, to shun exposure to the sun, have a most of them are pleasing, and many exceedingly lovely, but soon after they have attained their perfect growth, they rapidly decline."
go usually barefoot. The ladies wear a shirt and drawers, a very full pair of silk trousers, and a close-fitting vest with hanging sleeves and skirts, open down the front and on the sides, and long enough to turn up and fasten into the girdle, which is generally a cashmere shawl; a cloth jacket, richly embroidered with gold and having short sleeves, is commonly worn over the vest. The hair in front is combed down over the forehead and cut across in a straight line; behind it is divided into very many small plaits, which hang down the back, and are lengthened by black silk, a piece of black silk, and are lengthened by black silk, hang down the back, and are lengthened by black silk, hanging round the temples. The women of the lower orders have trousers of printed or dyed cotton, and a close waistcoat. All wear the long and elegant head veil. This is a simple "breath" of muslin, which passes over the head and hangs down behind, one side being drawn forward over the face in the presence of a man. A lady's veil is white muslin, embroidered at the ends, in gold and colours; that of a person of the lower class is simply dyed blue. In going abroad the ladies wear above their inner cape a loose robe of coloured silk without sleeves, and nearly open at the sides, and above it a large enveloping piece of black silk, which is brought over the head, and gathered round the person by the arms and hands on each side. A face veil entirely conceals the features, except the eyes; it is a long and narrow piece of thick white muslin, reaching a little below the knees. The women of the lower orders have the same out-door dress of different materials and colour. Ladies use slippers of yellow morocco, and abroad, inner boots of the same material, above which they wear, in either case, thick shoes, having only toes. The poor wear red shoes, very like those of the men. Among the upper class of the head, sometimes the dressing is rapidly becoming assimilated to that of Europeans in its most preposterous form.

In religion the Muslim Egyptians are Sunnites, professing the creed which is commonly termed "orthodox," and are principally of the persuasion of the Shafis, whose celebrated founder, the imam Eth-Shafis, is buried in the great southern cemetery of Cairo. Many of them are, however, Hanafites, to which persuasion the Turks chiefly belong, and in parts of Lower, and almost universally in Upper, Egypt, Malikites.

The civil administration of justice is conducted in four principal courts of judicature,—that of the Zaki, or chief of the police, where trivial cases are generally disposed of; the Divan el-Khedivi, in the citadel, in which the khdive or his deputy presides, and where judgment is given in cases which either do not require to be referred to the other courts yet to be mentioned, or which do not fall within their province; the Divan el-Mahkemeah, the council of the cadi (kides), or chief judge, who must be a Hanafie, and who was formerly a Turk sent annually from Constantinople, but is now appointed by the khedive, and paid a fixed salary of 4000 napoleons a year; and that of the muftie of the Hanafie, or chief doctor of the law, who decides all cases of difficulty. There are besides five minor mahkemeah, or courts, in Cairo, and one in each of the neighbouring towns of Boolak and Mesr El-Ateekah, from which cases are always referred to the court of the kides; and each country town has a native kides, whose authority is generally sufficient for the villages around it. The Council of the Ulkem, or learned men, consists of the sheykhs, or religious chief, of each of the four orthodox persuasions, the sheyhk of the great mosque called the Ashar, who is of the persuasion of the Shafis, and is sometimes its sheyk, the kides, and the chief (nakeeb) of the Shereeks, or descendants of the Prophet, with several other persons. This body was until lately very powerful, but now has little influence over the khdive. Cairo is divided into quarters (Harah), each of which has its sheyk, who preserves order among the people; and the whole city is partitioned into eight larger divisions, each having a sheyk called Shmdah. Various trades also have their sheikhs or chiefs, to whom reference is made in disputes respecting the craft; and the servants have similar heads who are responsible for their behaviour. The country is divided into governments, as before stated, each presided over by a Turkish officer, having the title of muadeer, and subdivided into districts under the control of native officers, bearing the titles "Mamoor" and "Nazar." A responsible person called Sheykh el-Boled (or "sheyk of the town" or "village") presides over each small town and village, and is a native of the place. It must also be mentioned that the El-Bed, or Upper Egypt, is governed by a pasha, whose residence is at Asyoot. Notwithstanding the consistent, able, and in many respects commendable, code of laws which has been founded on the Koran and the Traditions, the administration of justice is lamentably faulty. As is the custom throughout the East, judgment in Egypt is usually swayed by bribes, and a case is generally hopeless when his adversary is rich. To this rule there have been some notable exceptions, and the memory of a few virtuous judges is cherished by the people; but such instances are very rare. The moral and civil laws observed by the Muslim Egyptians, being those of El-Islam, will be noticed elsewhere. A great abuse formerly existed in Egypt in the system of consular jurisdiction. Natives were compelled to sue a foreigner before the latter's consul, and in nine cases out of ten lost their cause. Similarly it was very difficult for a foreigner of one nation to obtain justice against one of another nation at the latter's consolate. Thus abuses have now been done away. At the instance of Nubar Pasha, and after the deliberations of a European commission, three Courts of First Instance at Alexandria, Cairo, and Ismailia, and a Court of Appeal at Alexandria, were established in 1876, presided over by mixed benches of Europeans and natives, the former being the majority, and employing a new code based on the Code Napoleon, with such additions from Muslim law as were possible. These courts decide all cases between the Government or native subjects and foreigners, and between foreigners of different nationalities; and there can be no doubt that they will exercise a great influence for good on the administration of justice in Egypt. It is to be hoped that in course of time they may supersede the old native system in all causes. At present they do but supersede the consular system.

It is very worthy of notice, that in Cairo, as in some other Muslim cities, any one may obtain gratuitously an elementary education, and he who desires the fullest attainable education may receive that also without the payment of a single fee, by joining a class of students in a collegiate mosque. The elementary instruction which most boys receive consists chiefly of reading, and learning the Koran by heart; day schools, as charitable institutions, abound in Cairo, and every town possesses its school, a training fee to the fikas (or master) is the only expense incurred by the scholars. Girls are seldom taught anything beyond needlework. The children of both sexes, except those of the wealthy, have generally a very dirty and slovenly appearance; and often ignorance is adopted to avert the effects of the "evil eye," of which the Egyptians are in great dread. The children of the upper classes are excessively indulged, while the poor entirely neglect their offspring. The leading doctrines of El-Islam, as well as hatred for all religions but their own, and a great reverence for their parents and the aged, are early inculcated.
This deference towards parents cannot fail to strike every foreigner who visits Egypt, and does not cease with the childhood, but is by no means extinguished on marriage. Circumcision is observed at about the age of five or six years, when the boy is paraded, generally with a bridal procession, on a gaily caparisoned horse, and dressed in women's clothes. Some parents, however, and most of the learned, prefer a quicker and less expensive ceremony (Kornelius, xxviii.).

It is deemed disgraceful for a young man not to marry when he has attained a sufficient age; there are therefore few unmarried men. Girls, in like manner, marry very young, some even at ten years of age, and few remain single beyond the age of sixteen, they are generally very pretty. The bridegroom never sees his future wife before the wedding night, an evil which is somewhat mitigated by the facility of divorce. A dowry is always given, and a marriage ceremony performed by a Fikha (a schoolmaster, or one who recites the Koran), in the presence of two witnesses; the ceremony is very simple, but constitutes a legal marriage. The bride of a virgin is attended with great festivity and rejoicing, a grandee's wedding sometimes continuing eleven days and nights. On the last day, which should be that terminating with the eve of Friday, or of Monday, the bride is taken in procession to the grandee's house, accompanied by her female friends, and a band of musicians, jugglers, wrestlers, &c. As before stated, a boy about to be circumcised joins in such a procession, or, frequently, a succession of such boys. A Muslim is allowed by his religion four wives; but advantage is rarely taken of this licence, and very few attempt to keep two wives in one house; the expense and discomfort which polygamy entails act, therefore, as a restriction to its general adoption. A man may, however, possess any number of concubine slaves, who, though objects of jealousy to the legal wife, are yet tolerated by her in consideration of her superior position, and possessed power over them, a power which she often uses with great tyranny, but certain privileges are possessed by the concubine, especially if she have borne a son to her master. Such slaves are commonly kept only by grandees, the generality of the Muslim Egyptians being content with one wife. A divorce is rendered obligatory by the simple words "Thou art divorced," and a triple divorce is irrevocable under occasional circumstances. The hareem system of appointing separate apartments to the women, and sending them from the gaze of men, is observed in Egypt as in other Muslim countries, but less strictly. Mr Lane (ibid. ch. vi) says—"I believe that in Egypt the women are generally under less restraint than in any other country of the Turkish empire, so that it is not uncommon to see females of the lower orders flitting and jesting with men in public, and men laying their hands upon them very freely. Still it might be imagined that the women of the higher and middle classes feel themselves severely oppressed, and are much discontented with the state of seclusion to which they are subjected; but this is not commonly the case; on the contrary, an Egyptian wife who is attached to her husband is apt to think, if he allow her annual liberty, that he neglects her, and does not sufficiently love her, and to censure those wives who are kept and watched with greater strictness." The females of an Egyptian household never sit in the presence of the master, but attend him at his meals, and are treated in every respect as inferiors. The master, however, forms a remarkable exception to this rule, in rare instances, also, a wife becomes a companion to her husband. On the other hand, if a pair of women's shoes are placed outside the door of the hareem apartments, they are understood to signify that female visitors are within, and a man is sometimes thus excluded from the upper portion of his own house for many days. Ladies of the upper or middle classes lead a life of extreme inactivity, spending their time at the bath, which is the general place of gossip, or in receiving visits, embroidering, and the like, and in absolute dolce far niente. It is therefore no cause for wonder that their tone of morals is generally low. Both sexes are abstemious in their food, though fond of pastry, sweetmeats, and fruit. The principal meals are breakfast, about an hour after sunrise, dinner, or the mid-day meal, at noon, and supper, which is the chief meal of the day, a little after sunset. Coffee is taken at all hours, and is, with a pipe, presented at least once to each guest. Tobacco is the great luxury of the men of all classes in Egypt, who begin and end the day with it, and generally smoke all day with little intermission. Many women, also, especially among the rich, adopt this habit. Men who can afford to keep a horse, mule, or ass, are very seldom seen to walk, and numberless excellent asses are to be hired in Cairo. Ladies always ride asses and sit astride. The poorer classes are of course unable to observe the hareem system, but the women are in general carefully veiled. Some of them keep small shops, and all fetch water, make fuel, and cook for their households. The food of the poor is very meagre, flesh meat is rarely tasted by them, and (besides bread) dates, raw cucumbers, and onions are their common food, with soaked beans, roasted ears of Indian corn, &c.

In their social intercourse the Muslim Egyptians are regular, and observe many forms of salutation and much etiquette, yet they are very affable, entering into conversation with strangers at shops and elsewhere. Their courteous and dignified manners are very striking, and are combined with ease and a fluency of discourse. Of their mental qualifications Mr Lane (ibid. ch. xxi) remarks—"The natural and innate character of the modern Egyptians is altered, in a remarkable degree, by their religion, laws, and government, as well as by the climate and other causes, and to form a just opinion of it is therefore very difficult. We may, however, confidently state that they are endued, in a higher degree than most other people, with some of the more important mental qualities, particularly quickness of apprehension, a ready wit, and a retentive memory. In youth they generally possess these and other intellectual powers, but the causes above alluded to gradually lessen their mental energy." Their principal virtues are pieté and strong religious feeling; a strict observance of the injunctions of Khilalim, and a constantly professed belief of God's presence and overruling providence, combined, however, with religious pride and hypocrisy. Their common discourse is full of asseverations and expressions respecting sacred things, often, however, used with a levity which it is difficult for a person unacquainted with their feelings easily to reconcile with their respect for God. They entertain an excessive reverence for their Prophet; and the Koran is treated with the utmost respect—never, for example, being placed in a low situation—and this is the case with everything esteemed holy. They are faithful, and bear calamities with perfect resignation to the Divine will. Their filial piety and respect for the aged have been before mentioned, and benevolence and charity are conspicuous in their character. Poverty is therefore not accompanied by the distressing circumstances which too frequently attend it in Europe. Humanity to dumb animals is another virtue, and cruelty is openly countenanced in their streets, even to unclean animals; that is, however, unfortunately wearing off in consequence of their intercourse with Franks. Their affability, cheerfulness, and hospitality are remarkable, as well as frugality and temperance in food and drink, scrupulous cleanliness, a love of country, and honesty in the payment of debt. It should
be added, however, that the Egyptians rarely, if ever, exercise their social virtues but towards persons of their own persuasion and country. Their vices are indolence, obstinacy, and licentiousness, especially among the women, cupidity (mitigated by gentry), envy, a disregard for the truth, and a habit of cursing. Murders, and other grave crimes of this nature, are rarely committed, but petty thefts are very common.

"The Arabic spoken by the middle and higher classes in Cairo is generally inferior, in point of grammatical correctness and pronunciation, to the dialects of the Bedawees of Arabia, and of the inhabitants of the towns in their immediate vicinity, but much to be preferred to those of Syrna, and still more to those of the Western Arabs" (Lane, ibid. ch. ix.). The language varies in Upper and Lower Egypt, and is more correct inland than near the Mediterranean.

In the decay of Arab literature, Cairo still holds the chief place as a seat of learning, and its university, the Azhar, is undoubtedly the first of the Eastern world. Its principal professors teach "grammatical infusion and syntax, rhetoric, versification, logic, theology, the exposition of the Kor-an, the Traditions of the Prophet, the complete science of jurisprudence, or rather of religious, moral, civil, and criminal law, which is chiefly founded on the Kor-an and the Traditions, together with arithmetic as far as it is useful in matters of law. Lectures are also given on algebra, and on the calculations of the Muhammadan calendar, the times of prayer, &c." (Lane, ibid.). The students, as already remarked, pay no fees, and the professors receive no salaries. The latter maintain themselves by private teaching, and by copying manuscripts, and the former in the same manner, or by reciting the Kor-an. The students are now said to amount to the number of 11,000. Except the professors of literature, few Egyptians are taught more than to read and write; and of these, still fewer can read and write well. The women, as before mentioned, are very rarely taught even to read.

Science is but little studied, and barbers generally practise medicine and surgery. Mehmet Ali endeavoured to improve this state of things, by sending young men to Europe for the purpose of scientific study, and by establishing various schools, with the same object, in Egypt. His improvements have been continued by the present khedive, Isma'il Pasha, with some success.

In common with other Muslims, those of Egypt have very many superstitions, some of which are peculiar to themselves. Tombs of saints abound, one or more being found in every town and village; and no traveller up the Nile can fail to remark how every prominent mountain has the sepulchre of its patron saint. The great saints of Egypt are the imam Esh-Shafe'i, founder of the persuasion called after him, the seyyid Ahmad El-Bedawee, and the seyyid Ibrahim Ed-Dasookee, both of whom were founders of orders of dervishes. The former of these two is buried at the town of Tanta, in the Delta, and his tomb attracts many thousands of visitors annually to his principal festival; the latter is also much revered, and his festival draws together, in like manner, great crowds to his birthplace, the town of Ed-Dasook. But, besides the graves of her native saints, Egypt boasts of those of several members of the Prophet's family; the tomb of the seyyidah Zeyneb, daughter of 'Alee, that of the seyyidah Sakeeneh, daughter of El-Hoseyn, and that of the seyyidah Nefiseeh, daughter of El-Hosayn; all of which are held in high veneration. The mosque of the Hasseneyn (or that of the "two Hassen") is the most reverenced shrine in the whole country, and is believed by all to contain the head of El-Hoseyn. As connected with the superstitious practices of Egypt, dervishes must be mentioned, of whom there are many orders found in that country, the following being the most celebrated --(1) the Rifa'eeeyeh, and their sects the Iwaneeeyeh and Saadeeyeh; (2) the Kadereeyeh; (3) the Ahmadiyeeyeh, and followers of the seyyid Ahmad El-Bedawee, and their sects the Buyoomeeyeh, Shaaraeeeyeh, Shinnawyeeeyeh, and many others; and (4) the Bara'imeeh, or followers of the seyyid Ibrahim Ed-Dasookee. These are all presided over by a direct descendant of the caliph Mahommed, called the Sheikh El Bekre. The Saadeeyeh are the most famous for charming and eating live serpents, &c., and the Iwaneeeyeh for eating fire, glass, &c. The Egyptians firmly believe in the efficacy of charms, a belief which is associated with that in an omnipresent and overruling Providence. Thus the doors of houses are inscribed with sentences from the Kor-an, or the like, to preserve from the evil eye, or avert the dangers of an unlucky threshold; similar inscriptions may be observed over most shops, while almost every one carries some charm about his person. Among so superstitious a people, with whom, as we have already seen, science is in a very low state, it is not to be wondered that the so-called sciences of magnetism, astrology in the place of astronomy, and alchemy in that of chemistry, are in a comparatively flourishing condition.

Since the time of the Turkish conquest, the arts in Egypt have rapidly fallen into decay; this is partly attributable to the deportation of most of the skilled artificers of Cairo to Constantinople by the sultan Selim, but it is mainly owing to the misrule of the Turkish pashas, who have successively domined over this unfortunate country. Cairo contains the most splendid specimens of Arab architecture of any part of the Arabian empire; but at present new buildings are erected after the Constantinopolitan model, or, what is still worse, the purely European--both styles immeasurably inferior to the Arab, and very ill suited to the requirements of the climate. In like manner, every other kind of nature art is gradually perishing; and it is to be feared that even should the people be relieved from oppression and bad government, their industry will be encouraged rather to adopt imaginary improvements imported from Europe, than to cultivate the beautiful taste of their ancestors. The manufactures of the present inhabitants of Egypt are generally inferior to those of other Eastern nations, their handicrafts are clumsy, and the inevitable results of poverty everywhere evident; nevertheless, the curious shops, the markets of different trades (the shops of each trade being generally congregated in one street or district), the easy merchant sitting before his shop, the musical and quaint street-teams of the picturesque vendors of fruit, sherbet, water, &c., with the ever-changing and many-coloured throng of passengers, all render the streets of Cairo a delightful study for the lover of Arab life, nowhere else to be seen in such perfection, or with so fine a background of magnificent buildings.

Among the luxurious habits of the Egyptians must be classed the inordinate use of tobacco (as before mentioned). They are, however, rarely guilty of the vice of drunkenness, wine being prohibited by the Kor-an. Eaters of opium, and smokers of hemp, called haaseeh, are not uncommon, though they are always of the dregs of the people. The bath is a favourite resort of both sexes and all classes. In Cairo alone are upwards of sixty public baths, and every good house has a private bath. Their amusements are generally not of a violent kind, being rather in keeping with the sedentary habits of the people, and the heat of the climate. They are acquainted with chess, draughts, backgammon, and other games, among which is one peculiar to themselves, called Mankalah, and played with cowries. The game of the gendarmes requires great bodily exertion, and wrestlers, &c., are found in the country, though not in any number. Music is the most favourite recreation.
of the people of Egypt; the songs of the boatmen, the religious chants, and the cries in the streets are all musical. There are male and female musical performers, the former are both instrumental and vocal, the latter (called 'Almeh, pl. 'Awalin) generally vocal. The 'Awalim are, as their name ("learned") implies, generally accomplished women, and should not be confounded with the Ghowase, or dancing-girls. There are many kinds of musical instruments. The music, vocal and instrumental, is generally of little compass, and in the minor key; it is therefore plaintive, and strikes a European ear as somewhat monotonous, though often possessing a simple beauty, and the charm of antiquity, for there is little doubt that favourite airs have been handed down from remote ages. The prophet Mohammad condemned music, and its professors are in consequence lightly esteemed by the generality of Muslims, who nevertheless scruple not to enjoy their performances, and resort to the coffee-shops and to private festivities, where they are almost always to be found.

The Ghowase (sing. Ghowaseh) form a separate class, very similar to the gypsies, and are all brought up to the where it always manufactured, to the festivities, and at private festivities, but not public festivals, and at private festivities, but not public festivities. Their performances are too well known to need a description here, but it should be observed that the religious and learned Egyptians hold them to be improper. They dance in public, at festive and religious festivals, and at private festivities, but not in respectable houses, whether before the men or the ladies. Mehmet Ali banished them to Isna, in Upper Egypt; and the few that remained, occasionally danced in Cairo, called themselves 'Awalin, to avoid punishment. A most objectionable class of male dancers also exists, who imitate the dances of the Ghowaseh, and dress in a kind of nondescript female attire. Not the least curious of the public performances are those of the serpent-charmers, who are generally Afars, or Saades dwarfs. Their power over serpents has been doubted by most European travellers, yet their performances remain unexplained, and apparently they possess means of ascertaining the haunts of these and other reptiles, and of alluring them forth; they, however, always extract the fangs of venomous serpents. Jugglers, rope-dancers, and farce-players must day, the dam which closes the canal of Cairo is cut with much more interest, mostly by women. Following Cross, the Thughlaq, the tenth day, being the anniversary of the excepting on the Cross, the 17th of June, and is called that of the Drop (Loylas-Nuktah), because a miraculous drop is then supposed to fall, and cause the swelling of the river. The real rise commences at Cairo about the summer solstice, or a few days later, and on about the 3d of July a crier in each district of the city begins to go his daily round, announcing, in a quaint chant, the increase of water in the Nilmeter of the island of Er-Rodah. When the river has risen 20 or 21 feet, he proclaims the Wefa en-Neel, " Completion " or " Abundance of the Nile." On the following day, the dam which closes the canal of Cairo is cut with much ceremony, and this is the signal for letting the inundation over the surface of the country. A pillar of earth before the dam is called the "Bride of the Nile," and Arab historians relate that this was substituted, at the Muslim conquest, for a sign from which it was the custom annually to sacrifice, to ensure a plentiful inundation. A large boat, gaily decked out, representing that in which the victim used to be conveyed, is anchored near, and a gun on board is fired every quarter of an hour during the night. Rockets and other fireworks are also set off, but the best, strangely, after daybreak. The governor of Cairo attends the ceremony of cutting the dam, with the kadees and others. The crier continues his daily rounds, with his former chant, excepting on the Coptic New-Year's Day, when the cry of the Wefa is repeated, until the Saleeb, or Discovery of the Cross, the 26th or 27th of September, at which period, the river having attained its greatest height, he concludes his annual employment with another chant, and presents to each house some limes and other fruit, and dry lumps of Nile mud.

1 It may be mentioned here that the period of the hot winds, called the Khamsin, that is, "The Fifteen," is calculated from the day after the Coptic Easter, and terminates on the day of Ascension, and that the Muslims observe the Wednesday preceding this period, called "Job's Wednesday," as well as its first day, when many go into the country from Cairo, "to smell the air." This day is hence called Sheem en-Nesem, or "the smelling of the zephyr." The Ulama observe the same custom on the first three days of the spring quarter.
This brief account of the modern Egyptians would be incomplete without a few words concerning the ritual attendant on death. The corpse is immediately turned towards Mecca, and the females of the household, assisted by hired mourners, commence their peculiar wailing, while fixtures recite portions of the Koran. The funeral takes place on the day of the death, if that happen in the morning; otherwise on the next day. The corpse, having been washed and shrouded, is placed in an open bier, covered with a cashmere shawl, in the case of a man; or in a closed bier, having a post in front, on which are placed female ornaments, in that of a woman or child. The funeral procession is headed by men called "Yemeneyeh," chanting the profession of the faith, followed by male friends of the deceased, and a party of schoolboys, also chanting, generally from a poem descriptive of the latter state. Then follows the bier, borne on the shoulders of friends, who are relieved by the passers-by, such an act being deemed highly meritorious. On the way to the cemetery the corpse is generally, in Cairo, in the case of the northern quarters of the city, carried either to the Hassanyeh, or, if the deceased be one of the "Ulema," to the Azhar; or, in the case of the southern quarters, to the serryedheh Zeynab, or some other revered mosque. Here the funeral service is performed by the imam, or munster of the mosque, and the procession then proceeds to the tomb. In the burials of the poor at the grave; and sometimes a tomb. In the burials of the female relations and friends of the deceased.

The Egyptians, of whom there have always been great numbers in Egypt, appear to be even more degraded there than in other countries. They are held in the utmost abhorrence by the dominant race, and often are treated with much cruelty and oppression. Many are beggars and money-changers, &c. The quarter of the Jews, having been exceedingly filthy, and would give a stranger the notion that they labour under great poverty. But such is not the case; the fear of the Muslims induces them to adopt this outward show of misery, while the interiors of many of their houses are very handsome and luxurious. (S. F. — E. L. P.)

**Chronology and History.**

Before giving a sketch of the history of Egypt it is necessary to speak of Egyptian chronology. The difficulty of this subject has increased with the new information of the monuments. The statements of ancient writers were easily reconciled with half knowledge, but better information shows discrepancies which are in most instances beyond all present hope of solution. It may be said that we know something of the outlines of the technical part of Egyptian chronology; but its historical part is in a great measure conjecture before the times when we can check the Egyptian lists by their synchronisms with Hebrew and Assyrian history.

Dr Brugsch, in the second edition of his *Histoire d'Egypte*, frankly admits the growing difficulty of Egyptian chronology in terms which account for his not having continued his *Pharaonique pour servir à la reconstruction de l'Antiquité*, the opinions of which are modified in the later work. Baron Bunsen completed his *Egypt's Place*, but in the progress of the work made a great change in his theories. Professor Lepsius alone has maintained his views, as stated in the *Chronologie et Konigsbuch*, of which the general correctness has not been disproved, although in any new work it would be necessary greatly to modify the details. The words, already referred to, of Dr Brugsch, which close the introduction to his *History* (2d ed.), may be cited in justification of the differences between the present article and that of the last edition of the *Encyclopaedia.*

In comparing this edition with the previous one, the lector impartiali reconnaît facilement que nous avons remanié complétement le premier travail, et de plus, que nous nous sommes abstenus de fournir des hypothèses auxquelles seulement le temps et des découvertes futures pourront substituer les faits* (p. 3).

The Egyptians divided the civil day into 24 hours, 12 of the natural day and 12 of the night, counted from 1 to 12 during each period. Ordinarily the civil day began during the night, which was indifferently reckoned as belonging to the preceding or following day. Probably the beginning was at midnight. In the astronomical tables of the Tombs of the Kings the civil day probably begins with the night, and the reckoning is from the first hour, or six hours before midnight. The indication is, however, not conclusive, as the tables are of nights only, but one term used makes it highly probable (Brugsch, *Historien*, 106). We also find the so-called heliacal rising of Sotha indicated as marking the beginning of the New Year, but this may merely denote that the phenomena characterized New Year's day of the original Egyptian year, or of the fixed year, not that the civil day began with the 11th hour of night (cf. *1Q*, 99 no. 106; *1Q*, *Handbuch der Chronologie*, 1. 100-102).

The Egyptian month was of thirty days. The months are usually known by Greek names occurring in Greek documents, which were taken from the cultus connected with the months, and are thus the Egyptian sacred names. They are 1. Thoth, 2. Phaophi, 3. Athis, 4. Chebent, 5. Tybi, 6. Mabeh, 7. Pamanothe, 8. Rehmenoth, 9. Pachen, 10. Paynu, 11. Enpy, 12. Memu, after which they received the five Epagomenae. The names were applied to the Vague and Alexandrian years. The ancient Egyptians had a different system of names. With them the month was not divided into six seasons of four months each, of which the months were called 1st, 2nd, 3rd, and 4th. These seasons are called "shu," inundation, "jerri," winter, and "shenua" summer. The second and third
beginning of which had an original connection with the summer solstice, and the duration of which was probably the Egyptian measure of a solar year. This length of year would seem to be true linear years, if we are to accept M. Genisen's theory, that the Egyptians had discovered a method of adjusting their solar calendar with the lunar year by the intercalation of a leap year every 400 years in thirty years (\( \text{SI} \)). That the Egyptians at a later time used to have one of the calendar of last, in which three beginnings are mentioned, which stands at the beginning of the Egyptian year, although in the month commonly used in this phenomenon passed through all the seasons, and further that in the earliest times of Egyptian history this phenomenon occurred about the time of the summer solstice, and the conventional beginning of the year of the Nile, the three phenomena probably marked the beginning of the first season when the calendar was instituted (if \( \text{I} \) on the seasons, Brugsch, *Materiartsv., 54 seq*.).

The common year of the ancient Egyptians is that which has been called the Vague Year, because, on account of its length of 365 days it fell short of a tropical or a solar year, and thus passed through all the seasons. Thus this year was that in which the inscriptions are usually dated before the introduction of the Alexandrian year under Augustus, which appears from the Decree of Canopus (Hieron. I, 18, Greek l. 20, 27). The Egyptians also used a fixed year designed from the solar heliacal rising of Sothis, July 20. It contained 365 days, and was adjusted last by the intercalating of four years. It is uncertain how far back this year was in use (The Calendar of Miceru Hubbo, of the time of Ramses III., begins with the rising of Sothis, or the first heliacal rising, with its festival (Mather. p. 84). Perhaps at the time of this monument the phenomenon fell on the lst Thoth of the vague year, or within the month; or if the 1st Thoth is not used as a conventional notation of New Year's day in a typical form (Rud p. 84, 85). In the Roman period, after the Alexandrian year had come into use, there are inscriptions in the Alexandrian and Sothic calendars, but the common Egyptian notation of the months does not appear to have been usually applied to the Sothic year. An exception is noticed by Ptolemy Philadelphus, and another instance in which the month-name Tyb appears to be used for the Sothic calendar, while an Alexandrian name is employed for the corresponding months of the new year (Hieron. p. 62, 17. See on the whole subject, Brugsch, *Materiartsv.*).

The inconvenience of the vague year in relation to the festivals, on account of their connection with natural phenomena, led Ptolemy III. Epiphanus to reform the calendar by intercalating a day after every fourth year before the year next following (Decree of Canopus, Hieron. I, 22, Greek l. 24-25). Obviously this arrest of the common year was more convenient than the change to a fixed year already in use beginning at a different season. This new style was abandoned and the old resumed, but how soon we do not know.

Under Augustus a fixed year, called the Alexandrian, beginning on the 28-29th August of the Julian year, superseded the vague year. According to Lepsius, the Era of Augustus at Alexandria dated B. C. 30, but the first year of the new calendar, probably, B. C. 26, 27. The first year of the Sothic year began in 308 August of the proleptic year of Augustus. The new recompensation, however, in his opinion could not have been introduced before B. C. 2, and was probably introduced A. D. 153. (See Lepsius, *Ueber die Veranlagungszeit der Assyriener, Griechen, und Römer schen Chronologie*, Berlin Akad., 1859). Although it is quite possible that Augustus adopted a proleptic synchronism of the Egyptian and Roman years for the official Egyptian year, thus dating back his reign, yet it is more probable that there was some special reason for choosing the particular Egyptian year selected, which, moreover, was not the first of the Era of Augustus Brugsch put forward a theory, which is the more remarkable in its being on this question as it was of wholly independent origin.

He has shown reasons for supposing that a year beginning on the 29–30th August was in use in Egypt from the time of Dynasty VI (Hieron. I, 22, 25) that many of his correspondences are of the Roman period, and therefore probably refer to the Alexandrian year, but others cannot be so explained, and it seems probable that the year which under another date occurred the vague year was already in use long before (Mather. p. 17 seq). The Alexandrian superseded the vague year, and has remained in use to our times, namely, the Sothic year as the lunar year of the Arabs, but it has now given way to the Gregorian calendar.

At the time of Dynasty XII the Egyptians used four years. The first was a lunar year, a solar year, a lunar year, and a lunar year with an intercalation (Hist. 2nd ed. 99). The second of these years no doubt was the Sothic, the rendering is undoubted, the first, which is that of Dr Brugsch, is uncertain. If, however, it was so, we should have a difficulty in deciding to exactly which four months each season applied. It may be remarked that, according to the Copts, there are four months on the Egyptian calendar of the rise of the Nile, one day before the summer solstice, to the end of the inundation. If this was the ancient reckoning, and the rendering 'inundation' would correspond to spring and early summer. In support of this hypothesis it may be observed that the so-called heliacal rising of Sothis, whose connection with the calendar of early Egypt is evident from the Calendar of last, in which three beginnings are mentioned, which stands at the beginning of the Egyptian year, although in the month commonly used in this phenomenon passed through all the seasons, and the conventional beginning of the rise of the Nile, the three phenomena probably marked the beginning of the first season when the calendar was instituted (if \( \text{I} \) on the seasons, Brugsch, *Materiartsv., 54 seq*.).

The common year of the ancient Egyptians is that which has been called the Vague Year, because, on account of its length of 365 days it fell short of a tropical or a solar year, and thus passed through all the seasons. Thus this year was that in which the inscriptions are usually dated before the introduction of the Alexandrian year under Augustus, which appears from the Decree of Canopus (Hieron. I, 18, Greek l. 20, 27). The Egyptians also used a fixed year designed from the solar heliacal rising of Sothis, July 20. It contained 365 days, and was adjusted last by the intercalating of four years. It is uncertain how far back this year was in use (The Calendar of Miceru Hubbo, of the time of Ramses III., begins with the rising of Sothis, or the first heliacal rising, with its festival (Mather. p. 84). Perhaps at the time of this monument the phenomenon fell on the lst Thoth of the vague year, or within the month; or if the 1st Thoth is not used as a conventional notation of New Year's day in a typical form (Rud p. 84, 85). In the Roman period, after the Alexandrian year had come into use, there are inscriptions in the Alexandrian and Sothic calendars, but the common Egyptian notation of the months does not appear to have been usually applied to the Sothic year. An exception is noticed by Ptolemy Philadelphus, and another instance in which the month-name Tyb appears to be used for the Sothic calendar, while an Alexandrian name is employed for the corresponding months of the new year (Hieron. p. 62, 17. See on the whole subject, Brugsch, *Materiartsv.*).

The inconvenience of the vague year in relation to the festivals, on account of their connection with natural phenomena, led Ptolemy III. Epiphanus to reform the calendar by intercalating a day after every fourth year before the year next following (Decree of Canopus, Hieron. I, 22, Greek l. 24-25). Obviously this arrest of the common year was more convenient than the change to a fixed year already in use beginning at a different season. This new style was abandoned and the old resumed, but how soon we do not know.

Under Augustus a fixed year, called the Alexandrian, beginning on the 29-30th August of the Julian year, superseded the vague year. According to Lepsius, the Era of Augustus at Alexandria dated B. C. 30, but the first year of the new calendar, probably, B. C. 26, 27. The first year of the Sothic year began in 308 August of the proleptic year of Augustus. The new recompensation, however, in his opinion could not have been introduced before B. C. 2, and was probably introduced A. D. 153. (See Lepsius, *Ueber die Veranlagungszeit der Assyriener, Griechen, und Römer schen Chronologie*, Berlin Akad., 1859). Although it is quite possible that Augustus adopted a proleptic synchronism of the Egyptian and Roman years for the official Egyptian year, thus dating back his reign, yet it is more probable that there was some special reason for choosing the particular Egyptian year selected, which, moreover, was not the first of the Era of Augustus Brugsch put forward a theory, which is the more remarkable in its being on this question as it was of wholly independent origin. He has shown reasons for supposing that a year beginning on the 29–30th August was in use in Egypt from the time of Dynasty VI (Hieron. I, 22, 25) that many of his correspondences are of the Roman period, and therefore probably refer to the Alexandrian year, but others cannot be so explained, and it seems probable that the year which under another date occurred the vague year was already in use long before (Mather. p. 17 seq). The Alexandrian superseded the vague year, and has remained in use to our times, namely, the Sothic year as the lunar year of the Arabs, but it has now given way to the Gregorian calendar.

At the time of Dynasty XII the Egyptians used four years. The first was a lunar year, a solar year, a lunar year, and a lunar year with an intercalation (Hist. 2nd ed. 99). The second of these years no doubt was the Sothic, the
There are two weak points in all these systems. They rest to a greater or less degree upon numbers of governors or monarchs due to a single authority. The sum of 3555 years, which is the foundation of Professor Lepsius’s system, occurs in but a single passage, and the same is the case with 3496 years adopted by Dr Brugsch for the doubtful period of Dynasties XIII—XVII, it is taken from Manetho’s 511 years of the Shepherd dynasties. How, if both these numbers are corrupt? If they are not their escape is a marvel, considering to what authors and copies we owe them. Again, the sums of most individual dynasties rest on Manetho’s sole authority, and we have no monuments which at present hopeless. It is equally unfortunate that while certain dynasties are represented by monuments from which Manetho’s lists can be verified, others have left little or no records. Thus we have no monuments of Dynasties I.—III. until the close of the last. Then there is an abundance of monuments of Dynasties IV., V., VI. A blank follows without a monument that we can assign to Dynasties VII., VIII., IX., X. Records reappear under Dynasty XI.; of Dynasty XII they are abundant. Under Dynasty XIII they become scanty, and of XIV., XV., XVI., XVII. there are but a few, which may be of XV., XVI., or XVII. We have therefore three blank periods, the age before known monuments, the interval of Dynasties VII.—X., and the time of Dynasties X.—XII. About these three periods, the evidence of the Tware lists nor the monuments throw any light. It can be shown, however, that it is possible to make a cyclical system of the dynasties, which, as already shown, is by no means proved.

In the following sketch of Egyptian history no dates before the Christian Era will be given until the beginning of Dynasty XVIII, when approximate chronology becomes possible. Where, however, we may reasonably conjecture the length of a particular period of history, that will be stated.

The traditional age in Egypt is extremely obscure. History begins with the First Dynasty. The earlier period with Manetho, who is supported by the Turin Papyrus, is mythological, the age of the divine reigns, an idea also traceable in the monuments which treat certain divinities as sovereigns. This age is held to be spoken of on the monuments as that of the Shem-Ha-Berith, the first sons, or successors, of Horus, who, in mythology, aid him in his combats with Seth (Chabas, Ant. Hist., 7, 8; Brugsch, Hist., 2d ed. 23). Manetho completely divests the time of any historical character by making it cyclical. It might be supposed that the Egyptians had some records actually dating from this age, if we could accept M. Chabas’s reading of the Ptolemaic inscription relating to the plan of the temple of Denderah, in which it is stated that the original plan was found in the time of Pepi, of Dynasty VI., in ancient characters on a skin of the time of the Shehu-ur, it appears, however, from the context that this inscription was of the time of Khufu, of Dynasty IV., and consequently the parallel expression is merely used to denote remote antiquity (Dümichen, Bauwurkde der Tempelanlage von Dendera, 15, tav. XVI.; 18, 19, tav. XV.; cf. on the other side, Chabas, Ant. Hist., 2d ed. 7, 8).

Egyptian mythology has not been found to contain any allusion to a deluge, nor to have any connection with the Mosaic narrative in reference to the cosmogony and the early conditions of the human race. Similar terms have been pointed out, but the leading facts are wanting. Thus the Egyptian ideas of their prehistoric age have a strange isolation by the side of those of most other nations of remote civilization, which agree in one or more particulars with the narrative of Genesis. Discoveries may, however, modify this view.

1 Dr Brugsch accepts this difficulty by adding to the genealogy the reigns of Dynasty XVIII. (Hist., 2d ed. 30) so as to make the average length of reigns greater than that of the second, or some other of these reigns had a shorter average length than generations, he recovers lost time.

2 For an apparent agreement of this date and 375 years with the length of the reigns, see p. 160. The length of reigns is based on the genealogical method of Prof. Lepsius, and as these reigns have a shorter average length than generations, he recovers lost time.

3 It must be remarked that he modifies the numbers of Manetho wherever the figures are corrupt, as he thinks he can do so without the danger of falsifying the text and fails to correct them as they have come down to us. This system is continued with much skill in the Chronologia der Ägypter and Chronologia der ägyptische.
In Egypt stone implements have been recently discovered. Owing, however, to the abundance of historical monuments, the prehistoric remains have scarcely received due attention. We do not yet know whether these implements were used by the Egyptians or by savage tribes who may have made incursions into their territory. We find, however, the use of flint arrow-heads in the historical period from the paintings at Benec-Hassan (Dynasty XII.).

It is impossible to conjecture the duration of the prehistoric ages in Egypt. Mr. Chabas has proposed a space of 4000 years before the First Dynasty as sufficient for the development of the civilization which had already attained maturity in the time of the Fourth Dynasty (Ant. Hist., 9, 10). We are, however, so entirely ignorant of the causes of this civilization, and so unable to decide how far it was native to the soil of Egypt, that it is fair to abstain from any attempt to compute a period of the length of which the historical Egyptians themselves do not appear to have had any idea.

With Menes, in Egyptian Menes, the "stable," the history of Egypt begins. It is true that Manetho states cautiously of his successors of the Second Dynasty certain things which are evidently legendary. This must be the natural result of a want of monumental evidence, and a consequent dependence on tradition. At present no monuments are known before the time of the last king of Dynasty III., and thus may be the limit at which inscribed contemporary records began. It is, however, agreed by all Egyptologists that the founder of the Egyptian State is no legendary personage. All we know of him wears the air of history, and is consistent with the conditions in which a state would have been formed. Menes was of Thins, in Upper Egypt, and consequently the first dynasties are called Thinite Thuns, or Thos, in Egyptian Teni, was perhaps only a quarter of the more famous Abydos. Certainly it was occupied by the near neighbourhood of the sacred city. Menes, having gained the sovereignty of Egypt, which probably before his time was divided into two states, founded the city of Memphis. In order to gain sufficient room for the area he changed the course of the Nile by constructing a dike, which turned the stream more to the east. M. Lassus believes that this dike is probably represented by that of Kubaysah. The great temple of Piah, at Memphis, was then founded; and there is no doubt that the seat of government was, under Menes, or not much later, removed to the new city. Menes made laws and waged a successful war. After a long reign of sixty-two years he was killed by a hippopotamus. All this has a perfectly historical aspect. Only a legislator and warrior, and so a mighty hunter, could have set upon a stable basis the long-lasting fabric of Egyptian polity. The main qualities of the man who did this could not have been forgotten at Memphis, which was great and flourishing, the chief seat of Egyptian learning and wealth, before the close of the Third Dynasty. The reproach that Menes corrupted the primitive simplicity of the Egyptians is probably a perverted tradition, like that which changed the tyranny of Khufu and Khafra to impiety. In later times Menes was revered with other kings, but as far as we know had no special worship, a condition suitable to his historical character, now universally admitted.

Athothes, either Tota or Aot, the first or second successor of Menes, is related to have founded the palace at Memphis, and, being a physician, to have written anatomical books. A medical papyrus in the Museum of Berlin, connected with the Ramsee II. (Dynasty XX.), curiously illustrates the second statement. It contains a portion said to have been copied from a very ancient papyrus discovered in the time of Hap-pi, or Usaphados, a later king of the First Dynasty, and has been subsequently taken to Sents, or Setheus, of the next line (Brugsch, Hist., 2 ed., 42). Under Unephesus, the fourth Thinite king, a great famine, the first recorded, ravaged Egypt. He is also said to have raised the pyramids near Kochome. As Kekem is the monumental name of the part of the Memphite necropolis around the Serapeum, and north of the Pyramid of Steps of Sakkarah, Dr. Brugsch and others are disposed to consider that pyramid, which is a very archaic structure among pyramids, to be here intended. The use of the plural "pyramids" by Manetho does not stand in the way of the identification, as we know a case in which a small pyramid was built at the same time as a large one. We do not know the original purpose of the monument. Under the early dynasties it was used as the burial-place of the bulls Apus. As, however, their worship was introduced under Dynasty II., it may have been at this a royal sepulchre, like all other pyramids of which we know the use. Under Senecemps, the seventh king of the dynasty, Manetho speaks of many wonders and a very great plague. Thus the two chief scourges of Egypt appear in this remote age, suggesting a large population, and consequently the length of the period preceding the accession of Menes.

With Boethos, or Butan, the Second Dynasty begins. Manetho relates that in his time a great chasm opened at Boubastis and many perished. Frequent as volcanic shocks are in Egypt, it is long since an earthquake has been experienced in that country. There are, however, reasons, from the manner in which monuments have fallen and the records of earthquakes in Palestine in antiquity, for supposing that Egypt was anciently more subject to such calamities than in later times. The next king, Kaechos, Katak, introduced the worship of the bulls Apus at Memphis, and Mnoves at Helopolis, and of the Mensesian goat, and his name appears to commemorate these innovations, probably a necessary step owing to the increase of population, for animals locally worshipped were thus restricted in number. We also notice that already Helopolis and Mendes, besides Thins, Memphis, and Boubastis had been founded. Und the next king, whose name, Enoerhis, Bunnauiter, was probably commemorative of the new worship at Mendes, we read that a law was passed that women could hold the sovereign power. This might in a semi-barbarous condition be a relic of polyandry, but in Egypt the civilization of Dynasty IV. forbids such an explanation, and we must rather regard this new law as a proof of advancement. In consequence we find a few reigns of queens in the Egyptian lists, but only one of them, Sebek-neferura (Dynasty XII.), appears in those of the monuments. Succession through an heiress was, however, carefully respected, and it was perhaps for want of a son that Enoerhis made this edict. It may be chance, but Manetho calls each king of Dynasty I. after Menes, son of his predecessor, whereas under Dynasty II. he drops this characterization. Nothing more is told of this line but two marvels, that under Manetho's seventh king, Nephrecheres, the Nile was fabled to have flowed mixed with honey for eleven days, and that the eighth, Sesochers, was said to have had a height of 5 cubits and 3 palms, which is not improbably a confused account of a colossal statue. The royal house now changed by the accession of Dynasty III., the first of Memphites. Manetho relates how, under its head, Necerophes or Necerorhia, the Nebka of the monumental lists, the Libyans revolted from the Egyptians but returned to their allegiance terrified by a sudden increase of the moon. It is useless to speculate on the cause of this event which, unless it be legendary, was probably an eclipse; but the glimpse we thus obtain of an Egyptian dominion beyond the Nile valley at this remote age is most valuable. In Genesis the Lehabim, or Lubim, appear as a race kindred to the Egyptians. In the
Egyptian inscriptions they are called Rebu, or Lebu, and appear on early monuments as a dark people. Under the Empire they have Caucasian characteristics. The change was probably due to the great maritime migrations of the Pelasgic tribes, in which the Libyans have an important share. To the next king, Teosorhas, Manetho assigns the invention of building with hewn stones and cultivation of letters, and says that for his services to the Egyptians he called him Aesculapius. If the Pyramid of Steps dates from an earlier king, the first statement must be qualified, though it is to be remarked that the difference of constructive skill between that monument, if so early, and the works of Dynasty IV, would almost justify the hypothesis; and again the discovery of inscriptions of a less accurately ordered kind than those of Dynasty IV, may support the second statement; the third seems at variance with the Memphite worship of the Egyptian Aesculapius, Imb., etc. On the monuments contemporary history begins with the last king the lists assign to this dynasty, Senofem, probably Mausioth’s last but one, Saphurus. We may now take a retrospect of the age. It is in some respects curiously primitive in comparison with that which immediately follows it. Dr Brugsch has remarked the general absence in the kings’ names of the name of Ra, afterwards essential to throne-names, which from the metallic character of these they seem to have been, and the equally general absence of the names of other gods, Ra occurring once in the three dynasties and Sekeri once. Again he has observed the somewhat plebeian aspect of these names, as proper to men who sternly ruled the masses. Men is “the stable,” he who resists; Tota, “he who strikes;” Sena, “the terribleness;” Huni, “he who strikes.” Senofem is “the betterer.” As “the striker of the peoples,” for so he is called in his inscription at Wadede Magharah, in the Nineteenth period, he is a foreign conqueror.

From Senofem, at the close of Dynasty III, to the end of Dynasty VI, we have a succession of contemporary monuments by which History can be reconstructed, not only in its political events, but in those details of the condition of the population which makes an essential part of all real history. Under Senofem we find great material prosperity, and the arts already in that condition of excellence which makes the Pyramid age so popular. The most remarkable in the annals of Egypt. We also find foreign conquests, not as in the time of the Empire for glory, but with the view of extending the Egyptian rule to countries whose products were valuable for the arts. It is thus that this Pharaoh is the first king who has left a tablet in the Nineteenth period, where perhaps he, as Dr Brugsch thinks, was the first to plant military colonies to protect the workers in the mines of copper and the valuable blue stone called “mosfak,” and this idea is supported by his being afterwards worshipped there. He is also the first king whose pyramid is found with its special name on the monuments. Dr Brugsch thinks it is that now called the Pyramid of Meydorn, near which chapels of tombs bearing his name have been discovered, and a group consisting of two statues, remarkable as a splendid specimen of Egyptian archaic art. The subjects, it may be remarked, were usually buried near the pyramid of the reigning king. Senofem the betterer left a good name as a beneficent king, and his worship was maintained until the Ptolemiac period.

Khufu, the Sophei I. of Manetho and Cheops of Hero-

dots, immediately succeeds Senofem in the lists of the monuments, so that he may be regarded as the legitimate head of Dynasty IV. The list of that dynasty is as follows:—Khufu, Ratatf, Khafr, Menkauros, Shepseskaf, corresponding to eight kings in Manetho, in whom also the order is different, Ratatf (Iatosees) following Menkauros (M청소조), a natural consequence of the association in time of the builders of the three most celebrated pyramids, Khufu, Khafr, and Menkauros.

The age of the pyramid-builders is the most brilliant before the Empire. We can judge from the royal tombs of the magnificence of the kings, and from the sculptures around of the wealth of the subjects. The construction of the pyramids has perhaps been unduly marvelled at; we should know in what other manner the kings employed the vast amount of manual labour at their disposal, if we would estimate how much they could have effected by it in pyramid-building in the long period of time for which they ruled. If the two reigns of Khufu and Khafre extended over more than a century and a quarter, we may measure what we know them to have done against the works of other states during a like interval, and the comparison reduces our wonder.

The royal power at this time seems to have been very strong. So at least we may infer from the phraseology of the inscriptions, and from the fact that the kings threw much, if not all, of the force of the nation into personal monuments for their own memorial. Never in later times was the royal tomb the chief object of the king’s reign, or is he so completely detached from the welfare of Egypt. The pyramids with their priesthoods are proofs that then the Pharaoh was more positively worshipped than ever afterwards.

It must, however, be admitted that the great men whose tombs are planned around the pyramids enjoyed abundant wealth and ease. Their time was passed not in war or in state affairs, but in the management of large estates, probably royal gifts, and in superintending the handicrafts of their people, and giving no small share of their leisure to the pleasures of the chase, to hospitality, and to the enjoyment of musical performances. In the chapels of their tombs these occupations of everyday life are portrayed. There is no sign of war, no great military class. It is true that the common folk seem to have been very little in that land of abundance at least represented as happy. On the other hand, it is significant that the nobility include a large number of the royal family, and that the king is

1 The numbers of Manetho are irreconcilable with those of the Tutin Papyrus assigned by scholars to this period. There is evidence that they cannot be considered to be consecutives in the inscription which mentions a lady, a Queen Meretites, as a great favourite of Senofem and Khufu and attached to Khafr. M. de Rouge remarks that she must have been very old at the time of Khafr (See P. Dyn., 244 seq.), but in the list of Manetho the intervening reigns (Iatosees 25, Stephan 11.) amount to 91 years. If we allow her to have been 14 years old at the end of the reign of Senofem and to have lived a year into that of Khafr, her age would not be less than 106 years. This is very near the extreme limit of human life in the Egyptian inscriptions, 110 years, and it is based on the minimum of time possibly required to complete the pyramids. The length of early king’s lives in the Tutin Papyrus supports this view. Probably the reigns overlapped one another. This idea is supported by the two chief chambers in the Great Pyramid, which were roughly made M. de Rouge suspect that it was the tomb of two kings (Iat. 291, note 1). A sound argument for the chronology of the time might be found in the axis of the three chief pyramids. A pyramid was the great work of a king’s reign, and it was so constructed that it might be continually increased in size and yet easily completed at any time. The Great Pyramid would indicate a reign of 23 years; so, too, the Second, whereas the Third would, in its original size, each a shorter time. By this method we should be induced to accept Manetho’s numbers for Khufu, 63 years, and Khafr, 65, but to doubt the long reign of Menkauros, 63. It would be reasonable on the other evidence to make Ratatf contemporary with Khufu or Khafr.
not represented in the tombs, and when he is spoken of it is in terms of the most distant respect. Similarly there is an extraordinary reserve as to worship. Religious subjects are wanting, and the religious inscriptions are usually limited to the formula of dedication. The priesthood is already numerous, but it is connected with the service of the chapels of the pyramids. In the vast court a baneful bureaucratic class is already growing, in future to destroy the welfare of the people.

The reign of Khafra is principally marked by the building of the Great Pyramid. We learn from a curious inscription of a later date that he rebuilt the temple of Isis, near the Sphinx, carried out of the rock by some earlier king, and that he made a pyramid for the Princess Hent-sen in the same neighbourhood. The charge of impiety which the local tradition reported by Herodotus against Khafra thus fails, and the charge of tyranny associated with it, may be equally groundless. The cost of life in building the Great Pyramid can scarcely be compared with that of a long war under conditions resembling those of modern China. It should be noted that Khafra, as well as Khufu and Rastaf, were still objects of worship under Dynasty XXVI. (Brugsch, Hist., 2d ed. 57, 58). The only record of foreign conquest is a tablet in the peninsula of Sinau, commemorating what was probably no more than a successful maintenance of the posts already there established to guard the mines.

The reign of Khafra is commemorated, like that of Khufu, by the royal sepulchre and the tombs of subjects. From the latter we are able to contradict the tradition of his hostility to the national religion, in which Herodotus associates him with Khafra. The most interesting remains of the time are the statues of the king found in a well near the Sphynx, into which they were probably thrown either by a foreign invader or by early Christians or by Arabs, rather than in a popular revolt after his death (cf., however, Maspero, Histoire Ancienne, 73). A statue and a bust of Khafra from this find have been published by M. de Rouge (Sis. Prem. Dyn., pl. iv. v.). Both are remarkable works, showing a naturalistic style that makes them far superior to later statues. The king’s head is evidently a portrait, and the type is more Caucasian than the generality of later subjects.

Menkaure, or Mencheres, the Mycerinus of Herodotus, and the founder of the Third Pyramid, does not seem to have been specially revered in later times, in contradistinction to the report of Herodotus. It is, however, interesting to find connection with the tradition of his support of religion, that the Egyptian Ritual speaks of its 64th chapter as found by Har-hot-es, son of Mencheres, at Hermopolis Magna, where he made an inspection of the temples of Egypt, and brought as a precious document to the king (Brugsch, Hist., 2d ed. p. 59, 60). It would thus appear that the Ritual was not then completed, and Manetho’s statement that Saphis I., Khufu, wrote the sacred book may be another hint as to its date. It may also be noticed that the queen of Khafra was priestess of Thoth (Sis. Prem. Dyn., 277 scq.), and a noble, probably son of Khafra, was high-priest of Thoth at Hermopolis, a dignity held by another prince in the same reign (id. 250, 281).

The most interesting record of Menkaure is his wooden mummy-case, found by General Howard Vyse in the Third Pyramid. In the disappointing silence of those vast monuments, without a single ancient Egyptian writing save the graffiti of workmen and the inscriptions of native visitors, this solitary record of the time is the one authoritative voice from the royal sepulchres, and it tells us in its short archive formula that the whole of Osiris’ name had already matured. The king as Osiris has become divine and has vanquished his enemies (Brugsch, Hist., 2d ed., 58, 59).

The next family, Dynasty V., continued to rule at Memphis. Of its sovereigns we know but little. The last but one, Asa, is the first Pharaoh whom we know to have had two names, the throne-name as well as the ordinary one. To his son Ptah-hotep is assigned the ancient moral treatise already noticed in speaking of Egyptian literature, which is on the whole the best fruit of Egyptian thought that time has spared. The last king, Unas, varied the form of royal tombs, by constructing the great truncated pyramid now called Mastabat-Faraoun, or Pharaoh’s Seat, north of the Pyramids of Dahshoor (id. 67).

The Sixth Dynasty was probably a family of a different part of Egypt. It has left many records which indicate less centralization at Memphis than those of the earlier sovereigns, and mark the beginning of wars for predatory purposes and extension of territory. This change is accompanied by a less careful style of sculpture, and less pains in the excavation of the tombs, as though the Egyptians were gaining a larger horizon, or, it may be, exchanging religion for ambitions. The interest of the dynasty centres in the undoubtedly long reign of Pepa, second or third king of the line, and the inscription of Una. In this inscription we first read of great wars, and foreign conquered nations are spoken of by name. A military system had already begun, for we read how the king sent with Una an officer and soldiers to transport a sarcophagus for the royal tomb from the quarries of Turá. A war is then undertaken against the nomads of the eastern desert— the Amm (Shemtes) and the Herau, “those who are on the sand.” An army is levied from the whole population of Upper and Lower Egypt, as though there were no military caste. Nubians are also enrolled from several countries mentioned by name, which must have been subject to Egypt, and are drilled by Egyptian officers, including priests. Una is appointed general in chief. Five separate expeditions are conducted by him into the country of the Herau. It seems an error to suppose that this nation were Arabs of the desert, for the Egyptian general cut down their vines and their fig-trees (!). Another expedition was conducted by water against the same nation in a country called Takheba (De Rouge) or Tarkhaha (Brugsch), which M. de Rouge conjectures may be Arawa Petraw, a part of Syria, remarking that it was near Egypt, for the expeditions seem to have been annual. The external activity of the reign of Pepa is also attested by a tablet at Wades-Maghárah, and his public works by many inscriptions, among which we must not omit the occurrence of his name at Tanis, and in the inscription relating to the building of the temple of Dendarah. He founded a city called the “City of Pepa” in Middle Egypt, which has wholly disappeared, and tombs of his time are found in various parts of the Nile valley. His pyramid, which, like Memphis, was called the “good station,” Men-aner, was probably at the ancient capital, and may be one of the two great pyramids of Dahshoor, which

---

1 This Dynasty appears to have consisted of nine kings, who probably reigned nearly 200 years (Brugsch, Hist., 1 ed. 268).
2 Manetho assigns to Dynasty VI. a duration of 200 years. The monumental lists, themselves in disaccord, the Turau Danys, and the contemporary inscription of Una, show that Manetho’s list is here hopelessly corrupted. Una was in office under the immediate or second successor as well as under the immediate successor of Pepa, usually identified with Phapo, to whom the Egyptian historian assigns a reign of 100 or possibly 94 years. M. de Rouge has seen this difficulty, and discussed without finally resolving it (Sis. Prem. Dyn., 361 sqq.). M. Maspero has proposed a most ingenious restoration of the dynasty, on the idea that Nesperkara is the long-lost Phapo and that his family name must therefore have been Pepa (Hist. Aegypt., 96). This conjecture seems to be confirmed by the name of the later Nesperkara Pepa of the Tablet of Abyd, which is being guarded by the little Osiris as if to distinguish him from an earlier king of otherwise identical name.
are of later date than Dynasty IV., if we may judge from their structure, and both of which from their size imply reigns of the greatest prosperity and of long duration. Pepi was succeeded by his son Merena. The new king made Unas governor of Upper Egypt, and employed him to bring blocks of granite from Elephantine for his pyramid, and in various other works of which the inscription already referred to gives minute details, to obtain wood, which was provided by the prince of four Ethiopian nations already mentioned among those furnishing negroes to the great army of Pepi. We thus learn that tributary Ethiopia was ruled by a native prince or princess under the governor of Upper Egypt, who also had the power of establishing posts in the dependency. Unas made four docks and timber-yards in Ethiopia for building boats, and attached a chapel to each. We may thus expect to find some record of Egyptian rule at this early time, long before the complete reduction of Lower Nubia, in territories far south; for the timber-growing country does not begin for some distance within the tropics.

Merena was followed by his younger brother Neferkara, and, according to Manetho, the dynasty ended with the beautiful Queen Nitocris, whose name appears in the Turm Papyrus, but whose exact historical place is not certain. If she was buried in the Third Pyramid, of which Manetho, according to the copyists, makes her the builder, she enlarged the original work of Mencheres, and certainly no pyramid is so evidently not merely a double structure but one of double design. Nitocris is almost the only Egyptian whose historical character has been lost in a succession of legends. One version of her story is the most ancient form of that of Cinderella; in another, she still bewitched the Arab of the Middle Ages when he approached her pyramid (cf. Maspero, Hist. Anc., 94).

With the later part of Dynasty VI. the second great charm in Egyptian history begins, and we have no monuments to guide us until the close of Dynasty XI. According to Manetho, Dynasties VII. and VIII. were of Memphites, and IX. and X. of Heracleopolites, the Diospolite or Theban line comprising Dynasties XI., XII., and XIII. Whether the dynasties which intervened between the VIIth and XIIth were contemporary or successive, and how much time they occupied, cannot yet be proved. In the Tablet of Abydos, a series of kings unknown from other monuments follows Dynasty VI., and precedes two kings of Dynasty XI. In the Chamber of Kings of El-Karnak other and earlier kings of Dynasty XI. are named, with curious indications that it was first but a local line. To the period of the earlier kings of Dynasty XI. belongs Entef-aa, who reigned at least fifty years. It would appear that the Memphite kingdom waned, and that another line arose at Thebes, the house of the Entefs and Mentuhotepes. The power of these kings gradually increased, and at last one of them reigned under a single rule the whole of Egypt. (Maspero, Hist. Anc., 98, 99.) Probably the Heracleopolite line, Dynasties IX., X., was a local house contemporary with the Memphites or Thebans, or both.

With Dynasty XII., the Theban line was firmly established over all Egypt. In the circumstances referred to in the "Instructions" of Amenemhat I., his first king, to his son Usurtesen I., we have a glimpse into the unquiet condition of the country when the line arose (Id., 101). Similarly the custom of associating the heir apparent as king with his father, the peculiarity of this dynasty, indicates the dangers that then surrounded the throne (cf. Id. 105).

It is to the graces of Benee-Hasan that we owe most of our knowledge of the manners and arts of Egypt under Dynasty XII., and much of this history is told in the most curious fragments of the four tombs of a family of governors under the first five kings of this house. No one can have examined these beautiful tombs without being struck by the advance in architecture which they show, and the evidence of prosperity and cultivation afforded by their paintings. The subjects resemble those of the tombs of the earlier dynasties, but there is a greater variety, partly due to a more luxurious condition of society, partly to a more artistic form. It is sufficiently evident that the preceding dynasty (XI.) cannot have been weak, and the country under its rule distracted A time of prosperity must have preceded this bright period of Egyptian history.

Amenemhat I., probably a successful minister of an earlier king (Brugsch, Hist., 2d ed., 79, 80, 84), had an active and prosperous reign, ruling like Pepi beyond Egypt to the south, and occupying himself in the construction of various monuments. As the head of a new line he paid special attention to the boundaries of territories, to the regulation of the inundation, and to the confirmation of hereditary governors (Benee-Hasan inscr.) Brugsch, Hist., 2d ed., 94, 95.) A very curious view of the state of Egypt in his time is given us by the story of Sanoehe in a hieratic papyrus at the Berlin Museum (translated by M. Goodwin, in Records of the Past, vi. 131, seqq.). It is the history of an Egyptian who fled from the king and took refuge with a neighbouring prince, whose territory unhappily we cannot as yet determine, and after a long sojourn sought his sovereign's pardon and returned home to take into the favour of Amenemhat. The reception of the fugitive abroad, his home-sickness, and the kindness of the Pharaoh, who at the same time is described in terms of the most abject respect, form an interesting picture, and one remarkably illustrating several events in the history of Egypt.

Under Usurtesen I., the co-regent and successor of Amenemhat I., Egypt had reached its highest prosperity after the age of the pyramid-builders of Dynasty IV. The obelisk which still marks the site of Heliopolis, a fragment of a statue at Tanis, inscriptions on the rocks of the Sinaitic peninsula, and a stele from Waded Halfach, recording foreign conquests in the south, now in the Naples Museum, attest the splendour of this reign. The records of private individuals are, however, its most instructive memorials. Mentuhotep has given us a picture of the power and status of an Egyptian prime minister, holding all or nearly all the functions of the members of a modern cabinet, a position singularly parallel to that of Joseph, to the detail that even great men bowed before him. To this stele we owe the information that he gained successes against the Asiatics, the Herusha, and the negroes. (Brugsch, Hist., 2d ed., 91, seqq.)

Of Amenemhat II. and Usurtesen II., the next kings, there is little to relate but that Egypt continued to prosper. It was under Usurtesen III. that a great step in advance was made by the fixing of the boundaries of the Egyptian dominion beyond the Second Cataract, at Semneh and Kummeh, where this king built sanctuaries and fortresses, and placed great boundary-marks in the form of tablets. These in their inscriptions define the limits of the kingdom, and regulate the passage of negroes by the river (Id., 102). Here and throughout Nubia, Usurtesen was worshipped in subsequent times. He had introduced a settled government into the country, which long after was virtually a part of Egypt rather than a dependency. His successor Amenemhat III. is chiefly famous for his great engineering works. That care which the first Amenemhat bestowed on the regulation of the inundation seems to have been the great object of his reign. The rocks of Semneh and Kummeh bear registers of the height of the Nile in several
years of his reign. His great enterprise, the most successful of his kind ever carried out in Egypt, was the construction of a vast artificial reservoir, Lake Moeris, in the province now called the Faiyum, which received the waters of the Nile by a canal, and after the inundation spread them over the country. Its fisheries were also very valuable. Through the neglect of ages the site of Lake Moeris was forgotten until, in our time, M. Linant traced it. Near the lake, Menemhet III. built the famous Labyrinth, of which the remains were discovered by Prof. Lepsius during the Prussian Expedition to Egypt, and there raised a pyramid. The use of the Labyrinth is unknown, the pyramid was no doubt the royal tomb. Its moderate dimensions and the vast size of the lake show a remarkable contrast to the earlier great pyramids, with apparently no corresponding work of public usefulness. At the time which produced the Lake Moeris civilization, the Pyramid Age was long past. A 400 years and better may be supposed to have elapsed. The Pharaohs who bore the name 'Urur Papyrus: who generally bore the names Setek-hotep or Shepnet-sen-fra we know nothing, but that the line from which they are descended is that of Setek-hotep or Nefert-hotep. The longest reign is 10 years, and but one other reaches 10, the total of 13 reigned being 48 years and 23 days, and 5 years of months and 7 of days each. Putting the total at 50 years, the allowance for each reign is under 4 years. This must have been a time of disturbance, but not necessarily of disastrous war, for if we compare the rule of the second line of Memphite sultans we obtain an average reign of 5 years each. Thus we know to have been the consequence of domestic disturbance, and not of great public disasters at home or abroad. Dynasty XIV., of Xosets, the next in Manetho's list, is the first which had certainly its capital in the Delta. Beyond this fact we can only conjecture its importance and chronological place.

The dominion and conquest, at least in part, of Egypt by the Hyksos, or Shepherd Kings, is undoubtedly the chief cause of the obscurity of this age. The event did not happen until at least some time after the beginning of Dynasty XIII., for the eighteenth king of that line in the Turu Papyrus, who bears the significant name Mer-mesha, "the general," has left a record at Tanis near the eastern frontier, which was probably the chief city of at least one dynasty of the invaders.

Manetho, as cited by Josephus, allows for the stay of the foreigners in Egypt a period of 511 years, which has been supposed to be the interval between Dynasty XII. and Dynasty XVIII., by which they were expelled. Thus number, however, rests upon the single evidence of Josephus, and is moreover made up of several periods, which would render its evidence doubtful. A better means of measuring the period would be afforded by the monuments that of a Shepherd king. It may be supposed that this Shepherd king ruled 400 years before Ramesses II. could we place this foreign sovereign. All that can be said as to the chronology is that Dynasty XV. and XVI. were probably of Shepherds, and Dynasty XVII. was certainly of the Shepherds. It is probable that there was a break in the

The date of the Hyksos is thus told by Manetho. Under a king called Piamos, or Paimos (not recognized in the list or on the monuments), certain invaders from the East conquered Egypt without a battle, destroying the temples and slaying or enslaving the people. At length they made one of themselves, Salatus by name, king, who ruled at Memphis, and made all Egypt tributary. For the better protection of the eastern border he rebuilt and fortified the city Avaris, in the Sethroite nome in Lower Egypt, where he kept a great force of soldiers. He was succeeded by other kings mentioned by name, who, and their descendants, held Egypt for 511 years. After this the kings of the Thebans and of the rest of Egypt rose against the Shepherd rule, and a great and long war was waged, until Memnon-muthmosis drove the Shepherds out of all Egypt except Avaris, where his son Tuthmosis besieged them, and failing to take the place agreed to a capitulation, on the condition that they should be allowed to leave the country. Accordingly they went through the desert to Judea and founded Jerusalem. They were called Hyksos, or Shepherd kings, and, according to some, they were Arabs.

This narrative, notwithstanding a general confirmation from the monuments, is evidently not wholly correct. In particular it is inconsistent with all other evidence in attributing the foundation of Jerusalem to the Shepherds, which is evidently the result of an endeavour to connect their departure with the Exodus. Manetho seems to have preserved two Egyptian theories of the Exodus, which both explained that event as the result of external invaders. M. Manetto's researches in the ruins of Tanis have brought to light monuments of the Shepherds, and led to the discovery of others elsewhere, while M. de Rouge and other scholars have explained Egyptian documents connected with the war of independence. From these different sources we learn that the foreigners were of the Shemite or a kindred type, resembling the modern inhabitants of the north-east of Lower Egypt, who still retain the peculiarities otherwise noticed by Greek writers. Though the conquest may have been marked by violence, we find in their own monuments using and cultivating the manners and civilization of Egypt, and even giving a new and characteristic development to their art in their costly monoliths of granite, which show from their material that their rule extended to the southern boundary of Egypt. The war of independence arose between Apepe, one of their later kings, who is described as worshiping Soth only, and one of the three Theban kings called on the monuments Ra-akhen-Taa, at this time apparently a tributary prince. The war, contrary to Manetho's statement, does not seem to have been of long continuance, having been brought to a successful end by Aahmes, first king of Dynasty XVIII. between whom and Ra-akhen-Taa no great length of time can have elapsed. Manetho's text is again erroneous in making the conqueror Tuthmosis (Thothmes IV.), son (grandson) of Memnon-muthmosis (Thothmes III.), such

1 The Tablet of 400 Years states that this period elapsed from some point in the reign of the Shepherd king Set-as-heit Nub to some point in that of Ramesses II., and again Apepe, whose name corresponds to the Apepe, or Apophis of Manetho, almost immediately preceded Dynasty XVIII. Apophis is mentioned among the only Shepherd kings Manetho names. In the passage preserved by Josephus these are called the Shepherd rulers, who were probably the Shepherds, or Shepherd kings. The reference to the Shepherd kings, the XVIII., in the epistle of Apepe, though Enoseus transfers them to Dynasty XVII., perhaps known to Dynasty XVII. In Apepe, Dynasty XVII is of Shepherds and XVIII. of Shepherds and Thebans. If the identification of Apepe with the Apepe of Dynasty XVII. is correct, it would be a further proof of the identity of Apepe with the Shepherd of the Exodus; but this is not proved.
and fifth sovereigns of Dynasty XVIII. In his list; but this may be a confusion due to copies, as there is other evidence that he placed the conquest of the Shepherds under Amon, or Aahmes. The expulsion of the foreigners was not so complete as Manetho would have us imagine.

Several names in their territory remained Shemite, or the population non-Egyptian, and under Dynasty XIX. the prejudice that appears in Dynasty XVIII. seems almost removed.

It must be here noticed that Dr Brugsch has copied a remarkable inscription, from the tomb at Eilethya of Babs, whom he assigns to the latter part of Dynasty XVII., in which mention is made of a famine of successive years. A famine having broken out during many years, I gave corn to the town during each famine. There are but two known instances in history of a famine in Egypt lasting several years, the seven years' famine of Joseph and the seven years' famine of the Fatlmee caliph EI-Mustansir. Dr Brugsch has, therefore, argued with high probability that Babs records the famine of Joseph, and that the old tradition that Joseph governed Egypt under the Shepherd King Apophis is a true one (cf. supra, p. 723, note 1). To this we shall recur in speaking of the Exodus. (See Brugsch, Hist., 2 ed 174, seq.)

The beginning of Dynasty XVIII. (n.c. 1600-1500?) is marked by two great events, the union of divided Egypt under one head, and the victorious end of the great war with the Shepherds. Aahmes, probably a Theban prince, appears to have secured the supreme rule over the various princes of Egypt, without abolishing their rights, and to have gained Egyptian support by his marriage with Nefru-er, daughter of a king of Ethiopias. He then directed his whole power to the final liberation of Egypt. The tomb at Eilethya of Aahmes son of Abuna, an officer of the Egyptian flotillas, in an inscription relating his services, throws light on the events of this war. He passed his early youth in the fortress of Eilethya, one of the strong positions where the kings of Dynasty XVII. rallied their subjects. In the reign of Aahmes he was made officer of the ship called the "Call." Later he went to the flotilla of the north to fight. It was during the siege of the fortress of Avaris. He served in the vessel "Ruling in Memphis," a name no doubt given to commemorate the addition of the ancient capital to the dominions of Aahmes. An engagement took place between the Shepherds and Avaris. Subsequently Avaris was taken, and the young officer carried off three captives, whom the king granted him as slaves. Thus was in the fifth year of Aahmes, in the next we read of the conquest of Sharducas, the Sharuhen of the book of Joshws, in the south-west of Palestine. The narrative then adds that, after having slain the Shepherds of Assa, the king undertook a successful expedition against an Ethiopian country. (See Brugsch, Hist., 1 ed. 80, 81.)

This narrative, while generally confirming Manetho's story, corrects it in some particulars. It states that Avaris was taken, not that it was captured, and indicates a pursuit of the enemy within the territory of Palestine, where they were again conquered in a city which they attempted to hold. The Egyptian expedition was a reassertion of the Egyptian dominion to the south. Two tablets in the Turkish quarries record how, in the twenty-second year of his reign, Aahmes restored the temples which had fallen into decay, the blocks being removed by bulls under the charge of Phoenicians (Fenku) (Brugsch, Hist., 2 ed. 174, 175). It may be recalled that the Phoenicians were noted for their skilled smiths and masons in the time of Solomon, and that as early as the Exodus they were already great metal-workers.

From the time of Aahmes till the close of Dynasty XX. we may reckon the rise, fulness, and decay of the Egyptian Empire. It is a period of abundant monuments, sculptured and painted, and of many papyri, rich in records of the history, manners, and religion of Egypt. The state of the country may be glanced at in this place, where the Shepherd period closes, so as not to break the continuity of the subsequent history.

The sudden growth of prosperity at home and power abroad which marks the early reigns of Dynasty XVIII. is truly surprizing. The Egypt of Dynasty XVIII. is broken up and only slowly resuming; that of Dynasty XVIII. is at once solidly bound together, and soon to engage in designs of world-dominion never hinted at in earlier times. These conditions were the result of a great national war, in which the country discovered her hidden force, and was not content to use it only so far as was needful to make a strong Egypt like that of Dynasty XII. Having conquered her foreign rulers at home, she desired to add their native lands to her own dominions. The first effects of these designs were the enrichment of Egypt. In the early reigns of this house the wealth of the subjects as of the king rapidly grew. From the simple monuments of Dynasty XVII. and the first kings of Dynasty XVIII. there is a sudden advance to richness and splendour. Egypt was, however, becoming a military state. The king is constantly more powerful, and his public works more magnificent; the subjects, notwithstanding the luxury of individuals, have not that solid princely strength that we admire in those of the Pyramid kings and Dynasty XII. The appearance of the horse under this dynasty is most significant. The beasts of burden, the ox and ass, now yield in importance to the war-horse, and the landed proprietor journeys in his car whose ancestor went afoot in hand. Thus the military man succeeds the farmer. The priest is no longer a great man who has assumed sacerdotal functions, but one of a class immensely extended, reaching from the highest dignitaries, one of whom, strengthened by hereditary power, could at last unite the throne down to the mental class who lived upon the superstitious of the people. To carry on the government there grew side by side with soldiers and priests a vast official body, clever, ambitious, and unscrupulous, which rapidly on the true bureaucratic principle involved the administration in an entanglement which must have mainly led to the decline of the Empire. Justice, which was difficult at home, must have been almost impossible abroad. We now cease to hear of hereditary nomarchs studying the welfare of provinces to which they were attached by ancestral connection. All posts went by the royal favour. The common people fared ill in this age. Their function was to supply soldiers for the army and navy, and at first to take there share in the construction of public works; their only hope was to rise in the official class. Handicrafts and all labour were beneath a gentleman; hence no one could rise to his grade but through success at the schools, which were open to every one, and where a boy of talent had his chance of a career (cf. Brugsch, Hist., 1 ed. 16, 17).

Of the administration of provinces and conquered states we know little. Lower Ethiopia had always been ruled as a part of Egypt; this system was extended southward. At first the eastern states only paid tribute. Ultimately garrisons were placed in Palestine and Phoenicia (Brugsch, Hist., 1 ed. 130). Compared with the Assyrians the
Egyptians were civilized conquerors, and the sculptures of their battles do not represent any scenes of extreme cruelty. They do not, however, seem to have known the art of effectually holding their acquisitions, which had to be reconquered over and over again, until the inevitable tide of conquest on the other side set in, and the Empire fell.

On examining the earliest monuments of Dynasty XIX, we are startled by their astounding resemblance to those of Dynasty XI, a resemblance which would, had we no historical evidence on the other side, justify the leap of the Tablet of Abydos from Dynasty XII. to XIX. This may be partly explained as a renaissance of art due to a royal descent traced rather to Dynasty XI than Dynasty XII. Similarly under Dynasty XXVI, there was a reminiscence of the art of the age of the early Memphite Dynasties. We must also not lose sight of the local character of Egyptian art and its intense conservatism, which may have preserved an ancient type through many centuries. The early art of Dynasty XIX. has this character of a survival; that of Dynasty XXVI. is clearly a revival.

The art of this age is in some respects the finest Egypt produced; it is, perhaps, best about the time of Thothmes III. and Amenophis II., the middle of Dynasty XIX. It is inferior in naturalism to the art of Dynasty XIV., and in delicacy to that of Dynasty XXVI., but it has a certain splendour before wanting. After it had attained its highest point it slowly declined, partly from a decay in the vigour of the national character, perhaps more from the vast size of the later monuments, which must have led to a neglect of detail; though this neglect can only be seen by one who is thoroughly acquainted with the Egyptian styles. At all times there is an invincible patience in the mastery of material and the execution of detail. The temples, not the kings' tombs, are now the largest and most costly edifices; though a compromise with the old is effected by making grand temples as sepulchral chapels and religious monuments in their sculptures the events of the reigns. The tombs of subjects do not maintain the proportion of the royal tombs, commemorating in their sculptures the events of the reigns.

It will be well to glance for a moment at the Egyptian geography of this territory. There is great difficulty in explaining it, probably due to the different names apparently given to the same countries and peoples at one and the same time or at different times. We may, however, gain some insight into it by observing that more than one important geographical name can only be an Egyptian equivalent of Semitic names. Thus the Shem, who were wandering Arabs of the desert, who moved up as new into Palestine for pastureage or on predatory excursions, are nothing but "robbers." Most other names may be probably identified with Semitic equivalents: Syria is called Khal; this word is connected with Syria by the late equivalent Aser (cf. Maspero, Hist. Anc., vol. i. p. 161, note 1), which shows that the Egyptians then identified Syria and Assyria. The great nation of Syria in the time of Thothmes III. was the Ruten. These must be the Ruten of Lud, and may be also the Lydians in a primitive state. Under Rameses III. the Kheta, a northern division of the Hittites, held the political position of the Ruten, as though the Ruten had been absorbed. As the Ruten probably represented the Amarnans, so the Hittites represented the Canaanites. The Phoenicians appear to be the Kefa, in the time of Thothmes III. They held an important position in the Mediterranean, probably Cyprus, under Ptolemy III., and may be the Lydians of the 15th century B.C., as the Phoenicians were in the time of Rameses III. Some of the primitive nations whom the Bible mentions as supplanted in the period before Joshua have been represented on the monuments, nor is there any clear notice before the time of Sheshouk I. (Shashak) of the Terahitae. The period of Thothmes II. is one of Amaran supremacy, that of Rameses II. of Canaan; together they well correspond to the age before the Israelite conquest, while the condition of the time of Rameses III. suits the latest age of the Judges. The names of towns present less difficulty. Many are traceable in Biblical geography, and here but one indication occurs which may point to Israelite occupation.

The Egyptian conquests on the east being tributary, there were constant revolts on the accession of new sovereigns. It was thus that Thothmes III., on becoming sole ruler, had immediately to reduce the Ruten and their neighbours. This caused the series of eastern campaigns, which began in the twenty-second year, very early in his sole reign, and certainly extended to the forty-second, during which whole time there was seldom a year of repose. The history of these wars is told in the Annals of Thothmes III., which contrast favourably with those of the Assyrian kings.
If they were marked by barbarity, there is no boast of ought but conquest and the levying of tribute. The tribute no less than a combustible element is added to the great material civilization of the Asiatic states. Throughout, the Ruten are the most formidable enemies; the Kheta only appear. The first great achievement was the defeat before Megiddo of a confederacy led by the prince of Keteob, or Kadesh on the Orontes. In the battle only 85 of the enemys were killed, and 440 taken prisoners; but the magnitude of the success is proved by the capture of 2322 horses, 924 chariots, and the speedy surrender of Megiddo. This town, as in Josiah's time, was the key of the route to the Egyptian frontiers, and on its capture the king and the capital of the Ruten are mentioned as becoming tributaries. In the course of the wars Kadesh was captured twice, and the king of Egypt marched as far as Nineveh, and the name of Babel is mentioned. The reign of Thothmes was also marked by expeditions in Ethiopia, and then we first meet with the supposed Egyptian name of the Daumai, with whom he came in contact during some expedition in the Mediterranean. Great buildings commemorate this active reign, and we have a glimpse of the personal character of the king in the eccentric architecture of one of his additions to the temple of Amen-ra at Thebes. After a reign of 54 years 11 months, reckoning from the accession of Hatchepus, Thothmes III. was succeeded by his son Amenophis II. The accession of the new king was marked by a war in Assyria, in which he captured Nineveh. An incident of his eastern campaigns is remarkable for its Oriental barbarism. He brought back to Egypt the bodies of seven kings whom he had slain with his own hands. The heads of six were placed on the walls of Thebes; the seventh was sent to remote Napata in Ethiopia to hang on the walls to strike terror into the negroes. After a prosperous but probably short reign, Amenophis II. was succeeded by his son Thothmes IV., of whom we only know that he maintained his father's empire during a reign that probably did not exceed the nine years assigned to him by Manetho.

Amenophis III. succeeded his father, and, during a long and it seems mainly pacific reign, occupied himself in great architectural works. Two temples at Thebes owe their origin to him, that on the western bank, which was the funereal temple of his father in the western valley beyond, and of which little now remains but the two great statues in the plain, the Vocal Memnon and its fellow, and also the temple of El-Ukser on the eastern bank. In his time the dimensions of the structures of the earlier kings are surpassed, and the proportions of the most prominent monuments of the Empire are almost attained. Probably he was the first of the family after Aahmes who took a foreigner to wife. On the great scarabaei which commemorate his marriage with Queen Tai, we are informed that his rule extended from Mesopotamia to Southern Ethiopia.

Amenophis IV., the son of this foreign marriage, is the most perplexing character in ancient Egyptian history. Under his mother's influence he introduced a new religion, the worship of Aten, the solar disc, and after a time wholly suppressed the national religion, even changing his name to Khu-n-aten. Abandoning Thebes as the capital, he founded a new city in Middle Egypt, where he constructed a chief temple to Aten, and near which his officials excavated their tombs in the mountain. The type under which the king and his family and subjects are represented is unlike any other in Egyptian art. They are all of emaciated and distended figure, and surpassing ugliness. The king is treated with a servile reserve nowhere else seen on the monuments. His troops are mixed with foreign mercenaries. But we do not hear of foreign expeditions; every one is occupied in the duties of the new religion, without polytheism or idols. Flowers are the chief offerings and adorn the temple throughout; hymns chanted to the sound of harps are the form of worship. Was this a foreign religion, or was the Egyptian restoration of primitive belief! If it were Egyptian why was the sun called Aten, not Ra! The king was the son of a foreigner, and his type and that which marks his court, probably because some were of his mother's race, and art assumed the fashionable type for the rest, is not recognizable in any other characteristic representations of foreign races. It is neither Ethiopian nor Semite nor Libyan. The names of his mother and of her parents, the name of the sun-god, which is Egyptian, and the character of the worship, do not as far as we know point to any of these races. Certainly they are not Semitic. For race and religion we must probably look beyond the horizon of the Egyptian conquests. The type is not without an Indian aspect, and the religion has in its simplicity and the character of its worship a striking likeness to Vedism.

Khu-n-aten had seven daughters and no son. His successor As was his foster-brother and the husband of his eldest daughter. Under him the national religion was tolerated. Two other sons-in-law succeeded. Their line then or soon after came to an end, on the accession of Har-em-heb, or Horus, who claimed to be the legitimate successor of Amenophis III., either by descent or on account of the innovations of Khu-n-aten, who with the kindred of the Empire are never more seen in the monumental lists, in which Har-em-heb is seen as the immediate successor of Amenophis III. The same order is followed in Manetho's list, in which the house of Khu-n-aten follows Horus. What time this line lasted we do not know. Probably it did not exceed a generation. Horus occupied himself in destroying the monuments of Khu-n-aten and his successors, and no doubt is fully restoring the national religion.

Another family gained the throne after the reign of Horus, that of the Ramesides, forming Dynasties XIX. and XX.1 Ramses I., who seems to have been of Lower Egyptian extraction, and not improperly connected by ancestry with the Shepherd kings, seized the royal power, maintained his authority abroad by campaigns in the south and the east, and concluded a treaty of peace with the king of the Hittites. After a very short reign he left the crown to his son Setse I., or Sethos, who strengthened his position by marrying Tai, a granddaughter of Amenophis III. Ramses II., the son of this marriage, thus became the native king, and Setee made him his colleague at a very early age, no doubt to conciliate the Egyptians, a position at first ignored, evidently owing to the difficulty of defining it, but which ended in the virtual abdication of Setee (Maspero, Hist. Anc., 215–217). The troubles that preceded the reign of Ramses I. must have weakened the foreign dominion of Egypt. Wars in the east occupied the earliest years of Setee. The Kheta had now succeeded to the Ruten in the supremacy of Northern Syria. Although Setee conquered the Kheta and captured Kadesh, now their chief town, the war ended by the conclusion of a second treaty between the Egyptian and Hittite kings. It is not necessary to suppose, with M. Maspero (Hist. Anc., 215), that the Egyptian Empire was already waning, because it was thus barred off from Further Asia and obliged to meet the Hittite king on

1 The chronology of Dynasty XIX. presents one great difficulty. We cannot determine the length of the reign of Setes I. Manetho assigns him more than 50 years, which is most improbable, as Ramses reigned 67 years, and his father and mother were married before his father's succession. Ramses dates from his accession to his death 29 years. If we exclude a period of co-regency in the Manethonian numbers for Sethos, the size and beauty of Setee's tomb would imply a reign of not under 30 years. The length of his life cannot have been less than 130 years, and was perhaps as much as 150. It is clear that three generations and the rest of the probably long life of the king (Setee II.) whose birth marked the third, which would give 100+40+50 about 140 years for the total duration.
equal terms. The conditions were no doubt changed from those of the time of Thothmes III., but the list of the
confederacy which the next king of the Kheta led against
Rameses II., compared with that when Thothmes defeated
at Megillo, shows that the Kheta could bring into the field
much more formidable allies than did the Ruten. More-
over there was a change in the foreign policy of Egypt.
Phoenicia and Palestine were ruled by means of a chain of
fortresses held by Egyptian garrisons. (Brugsch, Hist.,
ed 135; Maspero, Hist. Anc., 215.) If the Empire
was narrowed in its limits, it was more solidly ruled; and
this is quite consistent with the conclusion of a treaty with
the Kheta. As a builder Setes I. is only equalled by Rameses
II. He constructed the great hall of columns of El-
Karnak, on the outside of the north wall of which he com-
memorated his victories in a series of most interesting
sculptures. His splendid tomb is in the Valley of the
Tombs of the Kings.

Rameses II. is without doubt the greatest figure in the
long line of the Pharaohs, and at the same time he is one of
the best character we have the best insight in. His reign by
training was in war and in government, for it cannot be a
pure figure of speech by which the tables found near
Dukkeh in Nubia says that when he was but ten years
old no monuments were executed without his orders.
(254, Hist., ed 137). This position was due to his
superior right to the throne. Before the death of Setes I.,
the maritime nations of the Mediterranean made a descent
on Egypt. The Shurdana, or Sardones, and the Turrahs,
or Tyrseni, allied with the Libyans in this enterprise.
Rameses defeated them so effectually that they do not seem
to have again attacked Egypt till the reign of his son
Mempth, about seventy years or more later. The captives of
the Shurdana instead of being employed in public works
were enrolled in the king's guard. After an expedition
against Ethiopia, Rameses, on the death of Setes, returned
to Egypt. Early in his sole reign the peace between the
Egyptians and the Hittites was broken. The king of the
Hittites formed a great confederacy. The nations of Asia
Minor, the Myssans, the Lyceans, the Dardans, the people of
Ilium, are found in the list of the poet of Pentaur, the
Egyptian Rameses, which appropriated records the oldest
war in which Troy had a part. To bring together the army
of the confederates time must have been needed. Probably
the war was determined on by the Hittites on the accession
of the new king. The great campaign was that of the fifth
year of Rames. The decisive battle was preceded by a
request, when the Egyptians were composed of the Arabs
(Shasu), were suddenly, while on the march, attacked
and routed by the enemy, who numbered no less than 2500 war-
chariots. It was only by the personal bravery of Rameses
that the Egyptians escaped destruction. This incident is
the main subject of the poem of Pentaur. But on the next
day the great battle was fought; the confederates were
beaten and retreated into Kadesh. The Hittite king now
sued for peace, which was granted. It was speedily broken.
In his eighth year Rameses took Shalam, probably Saleum or
Jerusalem, Marum (Merom), and Tapur (Dabir near Mount
Tabor), Bothanah, and Chorazim. In his eleventh year he
captured Ascalon. The war does not seem to have been
ended until the Hittite king Khetasas proposed conditions of
peace which he brought to Rames written on a silver
tablet. The treaty concluded on these bases in the twenty-
first year of Rameses is sculptured at El-Karnak. It is a
monuments in document form. Rameses was a true
offensive and defensive, with articles of extradition, remarkable for
his humanity, and others for the protection of commerce
(Maspero, Hist. Anc., 222, 223). Both kings swore to ob-
serve the compact, which was a renewal of the previous
treaties. It is remarkable that in the document the Hittite

prince, instead of being called the "tsi chief of the Kheta," is
now the "greatest king." the style given to Ramses also.
The eldest daughter of the Hittite king was taken in
marriage as queen by Rameses, in whose twenty-third
year Khetasas visited his son-in-law in Egypt. This alliance
does not seem to have been broken for full a century, and
then by conquerors who overcame the resistance of the
Kheta and carried them with them. The remainder of
the reign of Rameses appears to have been undisturbed by great
wars, and given up to those vast buildings which are found
throughout Egypt and Nubia, and which give him the first
place among the architect Pharaohs. About the thirty
year of his reign, his fourth son, the eldest surviving,
was made regent, and on the death of this prince in the fifty-
fifth year, Mempth the thirteenth son, now heir, took this
post, holding it for the rest of his father's reign, which
ended in the sixty-seventh year. Rameses must then have
been at least a hundred years old, perhaps more. He
married three queens, and apparently had by them 23
sons and at least 18 daughters. The whole number of his
children was 179, of whom 111 were sons and 68 daughters.
All are styled princes or princesses, but probably only the
children of queens had the right of succession.

Mempth succeeded Rameses II. There are but few monu-
ments of his reign. The principal event they relate is a
great excursion into the Delta of the maritime nations of
the Mediterranean allied with the Libyans. By this time
the Pelasgic tribes had wrested the dominion of the sea
from the Phoenicians. Some causes, perhaps famines, had
already disposed them to move from Asia Minor and the
Greek islands, seeking new establishments in Egypt. The
thought that Rameses II. defeated in the lifetime of Setes I.,
was now renewed, apparently on a more formidable scale.
The king of the Rebo (Libyans), with the warriors of
several tribes joined the Shurdana (Sardones), the Shaka-
lasha (Gikes), the Leku (Lyceans), the Turrahs (Tyrseni),
and the Akanyuha (Achaeans). They had already entered
Egypt and spread themselves over the west of the Delta,
where they intended to settle, when the Egyptian forces
attacked them and put them to rout after a battle of six
hours' duration. It is remarkable that in this confederacy
the Sh hurdana and A kanyuha are added to the former list,
and the Leku, who were true to the treaty, and during famines were
supplied with corn from Egypt, and the external provinces seem to
have continued quiet. But side by side with the king's
power that of the high priests of Amen-ra had grown to
formidable dimensions, owing probably to the interest Rameses
II., and Mempth showed for Lower Egypt, which put the
weight of Thebes on the side of the highest local functionary.
Mempth was not immediately followed by his son
Setes II. There intervened two reigns, those of Amen-
meses and Siptah, the first of the Rames family by descent,
the second, apparently, by marriage. They appear to have

1 Maspero thinks Ramses II. was at least 50 in the 21st year of
his reign (Hist. Anc., 250). This would make him at least 60
at the time of his death, and 50 at his accession. The latter
age is barely reconcilable with the fact of three of his sons of
the restricted class, which is evidently composed of the children
of successive queens, being engaged in the campaign of the 5th
year. Putting his marriage at 16, we make him at least 5 years
after the birth of these three sons, and cannot suppose the youngest to have
gone to war in his chariot under the age of 14. If so (14+4+14=)
the lowest age for the fifth year, and 28 for the 21st year,
the age of the eldest son, probably 14 at the birth of the
21st year. But it is obvious that probability is against these
extreme limits, and the fact that Ramses outlived twelve of his sons
of the shorter list in favour of a greater age.
been of a branch holding a local principality. Setes II. succeeded them and restored the legitimate line. His reign closed in anarchy. There was no longer one king: the chief of the nomarchs ruled and engaged in civil war. A worse period followed. A Syrian, Arsus by name, became chief of the nomarchs, society was dissolved, and the temple-services neglected. We are as yet unable to say how this revolution began. It seems to have had nothing to do with foreign wars, but to have been brought about by internal weakness. The time it lasted must have been long, according to the Papyrus of Ramesses III., from which alone we know of it. There "many years" are assigned to the period of the nomarchs and "years" to the rule of the Syrian.

As the Exodus is now generally held to have occurred in the later years of Dynasty XIX., its place in Egyptian history may best be here noticed. The view referred to was first carefully worked out by Prof. Lepsius. It rests upon chronological and historical grounds. Manetho, apparently adopting a tradition, placed the Exodus in the reign of Menptah. The number of generations assigned in the Bible to the interval from the Exodus to Solomon would bring the former event to about the same time. The approximate date is in accordance with that of the Rabbinical chronology, B.C. 1314-13. The coincidence is, however, valueless, for the interval from the Exodus to the building of Solomon's Temple, in the Rabbinical chronology, is that of the Hebrew text, 480 years. The date of the Exodus should therefore be about B.C. 1400. The difference between 1480 and 1314-13 is caused by an error in the date of the building of the Second Temple, which is put B.C. 354, only 46 years before the date of Alexander's death, which is dated B.C. 308, or 15 years too late. There is thus a mistake of more than a century in the cardinal date as the building of the Second Temple. If an event of this importance, occurring only 800 years before the drawing up of the chronology, is thus incorrectly dated, and a period of Jewish history obliterated, surely the date of the Exodus cannot rest upon any accurate information. The historical grounds are far stronger than the chronological. Manetho, relating, if we may trust Josephus, a current tradition that Ramesses, a current tradition, of the same name as himself, Amenophis the son of Papis, to cleanse Egypt of all lepers and other unclean persons, whom, accordingly, he set to work in the quarries. On their petition he gave them the city Avaris, left in ruins by the Shepherds. Having occupied the city, they chose one of themselves, a priest of Heliopolis, by name Osiris, as their ruler, who changed his name to Moses. He made laws particularly directed against the Egyptian religion, and sent messengers to Jerusalem to the Shepherds, who had been expelled by the Egyptians, asking their aid and promising to give them their old territory Avaris, and to assist them to subdue Egypt. Accordingly the Shepherds invaded Egypt, when Amenophis came against them, but for superstitious reasons did not fight them, and withdrew to the friendly king of Ethiopia, in whose country he remained thirteen years, his ally protecting the southern Egyptian border. Meanwhile the people of Jerusalem and the unclean Egyptians ravaged Egypt, and destroyed everything connected with the national religion. Afterwards Amenophis and his son Sethos, also called Ramesses, returned, and expelled the Shepherds and the unclean people. Chezmon gives a similar account with the same name for the king. Lycaon only calls him the king of Ethiopia.

The Egyptian evidence for the date of the Exodus would place it about this time. The geographical inquiries of Lepsius have been carried on by Brugsch, who, in a paper read before the Oriental Congress, has identified the principal geographical names of the narrative of the oppression and of the Exodus (Brugsch, Papyrus of Ramses, etc.). Ramses is shown to have been another name of Tanis. The occurrence of this name in Genesis and Exodus is most important as bearing on the date of the Exodus, for it is almost certain that it was given by Ramses II., who rebuilt the great temple of the town. Another cardinal piece of evidence is the mention of the 'Aperis, or'Apuris, as engaged in public works under Ramses II. and later kings, but not after Dynasty XIX. In this name that of the Hebrews has been recognized. If the identification were certain we should have much reason for dating the oppression under Ramses II., which would accord with the Exodus under Menptah.

The difficulties of this theory are not slight. On the chronological side Manetho's date is only dependent on a tradition, and we cannot fix the chronology of the dynasty, B.C. 1300 for Menptah being about the middle point in a doubtful two centuries. The evidence of the Hebrew genealogies therefore is not conclusive for a date identical with that of Menptah, which we cannot yet say is irreconcilable with the chronology founded on the interval of 480 years from the Exodus to the building of Solomon's Temple. If, however, the genealogies are to be taken as a guide for the chronology up to the Exodus, Egyptologists prefer for the period of the sojourn the longer intervals stated in the Hebrew text to the very short ones that would result from the genealogical method. Still greater difficulties arise when we give a critical examination to Manetho's story. It reads like a perverted narrative of the calamities which closed Dynasty XIX., for we cannot suppose two conquests by Asiatists and two expulsions, one by Menptah and Setes II., the other by Sethekh, who subdued the Syrian, nor resort to the violent hypothesis that the Papyrus of Ramesses III. attributes to Sethekh that which Sethes I. achieved. The name of Amenophis is suspicious, the two names of his son Sethos, "who is Ramesses," still more so; the recall of the Shepherds from Jerusalem, and the easy conquest of Egypt without a battle, all read like a legend founded on a fusion of the two periods of Eastern occupation. There is, moreover, another suspicious circumstance in the occurrence of the name of Bocchoris in two versions of the story. This would either point to Bocchoris of Dynasty XXIV., in whose time it is quite possible that there was a large number of Israelite fugitives in Egypt, or to some other king of the same or a similar name: we do not, however, know of any earlier Bocchoris. It may be reasonably asked whether this story has anything to do with the Exodus. Those who hold that it has yet, in common with all Egyptologists, argue, when they examine the Biblical data, on the ground of the minute accuracy of many of these data. If, then, the two narratives, that of Manetho and that of the Papyrus of Ramesses III., relate to the Exodus, they may reasonably be the interpenetration of a Minoan is a faultily and distorted one. It is, however, quite possible that Manetho may have known when the Exodus happened, and yet may have confused it with an event of the same period. The argument from the Biblical data that Ramses II. ruled during the oppression of the Israelites is very strong, though it may be conjectured that a redactor has substituted the later name Ramesses for the earlier Zoan.
The name of the 'Aperu, if certainly that of the Hebrews, would be decisive, but it is not a proper Egyptian equivalent, and names are the transcription of Semitic geographical names into Egyptian, that upon them mainly depends the theory of the sounds of the Egyptian alphabet developed by M. de Rouge and adopted by Dr Brugsch. Here, again, the evidence is inconclusive.

The arguments which would place the Exodus in any other period of Egyptian history are but slight. There is indeed the remarkable occurrence of a name similar to that of Jacob, or identical with it, in a record of the conquests of Thothmes III. This may only be a reminiscence of Jacob, as M. de Rouge suggests, but it would be more natural to take it to indicate that the Exodus was anterior to the time of Thothmes, and there are other names in the list which may possibly point to the same conclusion. Yet the preponderance of evidence is at present greatly in favour of the occurrence of the Exodus towards the close of Dynasty XIX. It is not, however, necessary to accept the date of Prof. Lepsius, in our present state of uncertainty as to the chronology of Dynasty XIX. It is also not a necessary consequence of accepting this historical synchronism, that we should take Manetho's narrative of the Exodus as more than identification with it of an event of the same period. There may seem but unsatisfactory results of the great erudition which has been bestowed on this question. We refrain from speaking more positively when a discovery may at any moment render speculation needless.

If the Exodus took place towards the close of Dynasty XIX., when did the period of oppression and the government of Joseph fall? The reckoning by generations would place Joseph in the later part of Dynasty XVIII., and the oppression under Ramses II. downwards. It is, however, very generally acknowledged that this method of computation is not consistent with the growth of the Israelites from a family to a nation during the sojourn in Egypt. Scholars are therefore disposed to choose a reckoning by years. Here the Biblical data give either 430 years exactly for the sojourn and 400 for the oppression, or else 215 years for the sojourn. The longer periods are those generally preferred. If we reckon by them, the government of Joseph would have fallen under the last Shepherd king, and the oppression would have probably begun under Ashmes, to be greatly increased in intensity under Ramses II.

Somewhat, a chief probably of the line of Ramses II., overthrew the Syrian intruder and again restored the Egyptian monarchy. His short reign, which begins Dynasty XX., was probably entirely occupied in reorganizing the administration of Egypt. Ramses III., whom his father had already made his colleague (Maspero, Hist. Anc., 262), succeeded to a united Egypt but a distracted Empire. Evidently in the time of anarchy every province and tributary state had fallen away. The new king was equal to the effort of repelling invasion at home and reconquering lost territory abroad. In his fifth year he defeated the Libyan tribes who had invaded the west of Lower Egypt.

In his eighth year he met another attack from the opposite quarter. The Tanana ( Данані ) and the Takkaru ( Теурауані ), who now first appear, forming with the Tursha ( Тиршуа ), Wasaba ( Wasoа ), Shashlahu ( Сашало ), Leka ( Леко ), and Pelestea ( Фелстауа), a great confederation, which attacked the east of Egypt by sea and land. Their army conquered and carried with it the Kheta and surrounding tribes. Their fleet, manned by the Takkaru and bharadus, reached Egypt at the same time. The Egyptian army and fleet encountered and defeated them. This campaign, and particularly the sea-fight, form the subjects of interesting reliefs in the great sepulchral temple built by Ramses III. in western Thebes. In his eleventh year a second invasion of the west of Egypt, by the Libyans, aided by the Tursha and the Leka, was equally unsuccessful. The eastern provinces and tributary states were recovered, and an expedition was sent to the Somaliland country on the eastern coast of Africa or Arabia Felix. This last great conqueror finally preserved Egypt from the maritime nations. The course of their migrations seems to have been changed. All that remained of their invasions were the Phalistine settlements in Palestine and one of the Waduba, a Libyan tribe, in the Delta, from whose race the Egyptians drew their names.

We refrain from speaking of the city of Gezer, which he gave to a plotted people, the ‘Ameri, if the numbers are correct, Pseuomeni II., Harpsheche, last king of Dynasty XXI. He seems to have endeavoured to restore the military power of Egypt, for he made an expedition into Canaan and captured the town of Gezer, which he gave to his daughter, Solomon's queen.

During the late period of the Empire, partly through marriages of the Pharos, partly in consequence of the large employment of mercenaries, chiefly Libyans, great settlements of foreigners, Asastic as well as African, were established in Egypt. So far from being deterred, a multitude of Semitic words were introduced into Egyptian, and it even became the fashion to give a Semitic form to native words (Maspero, Hist. Anc., 357, 338). A Shemite family, settled at Bubastis, or in the Bubastite
no doubt seizing had no holds, and obtained the sovereignty of Egypt, leaving the success, had not the yet unconquered princes called in the descendant of the Priest-kings of Thebes, was not to recover his ancient dominions. In one brilliant campaign the country, and would probably have achieved complete pflest-kl~g be of already again set in, and the country commanded. of of Egypt usually the eldest son, and gave high governments to other B.C. XXII. underwent an important change. They made the twentieth year of the Egyptian king's reign, his of Amen-ra an office of a prince of the family, but probably kindred to the Bubastites, Time ThebBlS remarkable sculpture at the temple of El-Karnak in Egyptian history. The Hebrew chronology is indeed small Bedawee tribes. items are far less important, and the Hagarenes recur not like the rolls of the conquerors of the palace. A remarkable sculpture at the temple of El-Karnak in Egypt, which is remarkable for the name Nemrut, or Nimrod, borne by non-kingly members of the family. Probably it came from the further East. Sheshonk L., the Shiakhe of the Bible, may have gained the royal power peaceably. His son Osorkon married the daughter of the last king of the Tanite Dynasty, to whom Sheshonk succeeded. He seems early to have entertained the design of restoring the Egyptian rule in the East, for he received Jeroboam when he fled from Solomon. The revolt of the Ten Tribes enabled him to carry out this project, and late in his reign he marched against Rehabom, and returned with the treasures of the Temple and the palace. A remarkable sculpture at the temple of El-Karnak gives a list of 130 names of towns and peoples conquered by Shishak in this expedition. Long as is the list, it is not like the rolls of the conquerors of the Empire. The items are far less important, and the Hagarenes recur several times, as if to record the subjugation of a series of small Bedawee tribes. Cities of Judah and Israel appear in the list, but the towns in the kingdom of Jeroboam seem to have been Canaanitic, and Canaanites, and it is probable that the Israelite king was not averse to their overthrow. With this occurrence we gain the first good chronological footing in Egyptian history. The Hebrew chronology is indeed not as yet fixed. The Assyrian monuments seem to indicate a reduction of at least twenty-three years in the ordinary dates. The invasion of Shabak is ordinarily dated n.c. 971, but may thus have to be lowered to about n.c. 948; and as it probably took place in about the twentieth year of the Egyptian king's reign, his accession may be dated approximately n.c. 967.

The government of Egypt under the kings of Dynasty XXI. underwent an important change. They made the high-priesthood of Amen-ra an office of a prince of the family, usually the eldest son, and gave high governments to other princes. Thus the power of the Pharaoh ultimately became merely nominal, and Egypt resolved itself into an aggregate of principalities. A further cause of decay was the importance of the Libyan mercenaries which each of the princes commanded. Under a new dynasty, XXIII., said to be of Tanites, but probably kindred to the Bubastites, Egypt was, for a time at least, reunited under a single rule, but towards its close the process of disintegration had already again set in, and the country was divided among nearly twenty princes, at least four of whom took the royal insignia (Maspero, Hist. Anc., 378 seqq.). Among these small princes but one was capable of attempting to reunite Egypt under his rule. This was Tafnekht, Taophachers, prince of Saas, who reduced great part of the country, and would probably have achieved complete success, had not the yet unconquered princes called in the prince-kings of Napata, Panphi Memiamen. While Egypt had declined, Ethiopia had constantly risen, and at this time part of the Thebans owed it allegiance. Panphi, the descendant of the priest-kings of Thebes, was not unwilling to recover his ancient dominions. In one brilliant campaign he defeated Tafnekht and his allies, captured their strong-holds, and obtained the sovereignty of Egypt, leaving the small princes to rule as his vassals. The ancient Empire was thus in part restored, but as it was ruled from Ethiopia, and the little princes constantly strove for independence, it had no real durability. Panphi was succeeded by Kasha, who was probably an Ethiopian, giving his throne to his intermarriage with a princess of the Theban line.

Bokenranf, or Bocchoris, son and successor of Tafnekht, no doubt seize this occasion, was able to carry out the project of his father and make himself king of Egypt. After a short reign marked by energy and prudence he perished in a fresh Ethiopian invasion. Shabak, or Sabakon, conquered Egypt, and having taken Bokenranf in his capital, Saus, put him to a cruel death. It was no longer an Egyptian prince who ruled at Napata; all the circumstances we know of Shabak and his dynasty indicate an Ethiopian prince, governing Egypt as a conquered country, not as their ancient territory. Still Shabak's connection with the priestly line was not forgotten. His sister, Queen Ameniritas, governed Thebes, and the power of the local rulers was limited, not destroyed. Hoshes, king of Israel, sent presents to Shabak,1 who was subsequently drawn into a confederacy of Syrian and other princes against Sargon king of Assyria, but, as in all these wars, the Ethiopian king was a tardy ally. His capital lay too far south, and in crossing the eastern border of Egypt he left the ill-affected princes of the Delta in the line of his communications. He therefore came into the field too late, and it is said in Egypt that Shabak and the Assyrians and experienced a disastrous defeat at Raphia. He lost great part of Egypt, in which the small princes again established themselves, now as vassals of Assyria, Shabak only retaining Ethiopia and part of Upper Egypt.

Shabakot, or Sebutsus, was the son and successor of Shabak. He made himself supreme king in Egypt, but appears to have lost Ethiopia to Tahraka. Towards the close of his reign the Egyptian dynasts joined in an alliance against Sennacherib, who had recently succeeded Sargon. The confederates were defeated, or made their submission one by one. The Egyptian princes lost a battle in southern Palestine, in the territory of their ally Henochiah, who was the last in the East to submit. But the Egyptians again advanced, encouraged by Tahraka, king of Ethiopis, who marched to their support. No battle was fought. The Assyrians moved against the Egyptians, but in one night the invading army perished, and Sennacherib fled to Nineveh. The tradition of the Egyptians agrees with Biblical history in relating the destruction of the Assyrians as miraculous; and it should be noted that for the rest of his reign Sennacherib never ventured again to invade Palestine. During this interval of repose Tahraka entered Egypt, slew Shabatok, and made himself master of the whole country (n.c. 692). After twenty years of what seems to have been a peaceful reign, the Assyrian war began afresh, Esarhaddon, son of Sennacherib, marched to their support. Assyrians moved against the Egyptians, but in one night the invading army perished, and Sennacherib fled to Nineveh. The tradition of the Egyptians agrees with Biblical history in relating the destruction of the Assyrians as miraculous; and it should be noted that for the rest of his reign Sennacherib never ventured again to invade Palestine. During this interval of repose Tahraka entered Egypt, slew Shabatok, and made himself master of the whole country (n.c. 692).

Soon after Esarhaddon's death Tahraka was deposed, and his son Assur-bani-pal, who speedily invaded and reconquered Egypt, driving out Tahraka and restoring the tributary princes. As soon, however, as he had left, a conspiracy broke out, and these chiefs sent emissaries to Tahraka, who were overcome by the Assyrians, and Neku and two others sent in chains to Nineveh, before Tahraka could come to their aid. But he again reconquered Thebes and Memphis. Assur-bani-pal now made a politic use of the Egyptian party, treated Neku with honour, and sent him back to Egypt as ruler of Saus, giving a second principality to his son Pammene. Neku returned to find that Tahraka

1 With this transaction Shabak's record at El-Karnak of the tributes of Syria has been connected (Maspero, Hist. Anc., 390).
SAITE KINGS.

EGYPT

had left Egypt (B c. 666). Urdamen, Tohrak's son-in-law and successor, held Upper Egypt, and at once attacked the Assyrians, captured Memphis from them, and took Neku, whom he put to death, while Psammetik fled into Syria. Aswah-bani against the new king, defeated Urdamen, and sacked Thebes, carrying the whole population captive. The twenty principalities were again set up, but Psammetik was not the chief.

After a time the Egyptian princes became independent of Assyria, but they had once more to submit to an Ethiopian invader, Nount-Mewmen, who reconquered the country without much difficulty, but does not seem to have long held it. The Satte prince Psammetik, whose ambition excited the jealousy of the other dynasts, at last achieved the object for which his predecessors had perniciously fought. By his aid Carian and Ionian mercenaries he put down his rivals, and by a marriage with the niece of Shabak rendered his line legitimate. This alliance with a princess only a generation younger than the first Egyptian king brings into striking relief the partial successes of the Assyrians, captured Memphis from them, and took Neku, but does not seem to have long held it. The Satte prince Psammetik, whose ambition excited the jealousy of the other dynasts, at last achieved the object for which his predecessors had perniciously fought. By his aid Carian and Ionian mercenaries he put down his rivals, and by a marriage with the niece of Shabak rendered his line legitimate. This alliance with a princess only a generation younger than the first Egyptian king brings into striking relief the partial successes of the Assyrians. It was not the first time the Assyrian influence was distinctly felt. Assyria had fallen, and the Babylonian invasion was imminent, but the sea power of Egypt was not yet completely lost. In the reign of Psametik I. the Persian king Croesus was defeated by the Phoenicians, who invaded Egypt, defeated the Persian forces and took Neku. This was not the last of the Persian invasions, for in the reign of Psametik II. the Persian king Cambyses took Neku and set up his brother, Ahasuerus, as king of Egypt. From this time onwards the Persian power extended over the whole of Egypt, and the Persians became the dominant power in the East. The Persian king Cambyses was defeated by the Phoenicians, who invaded Egypt, defeated the Persian forces and took Neku. This was not the last of the Persian invasions, for in the reign of Psametik II. the Persian king Cambyses took Neku and set up his brother, Ahasuerus, as king of Egypt. From this time onwards the Persian power extended over the whole of Egypt, and the Persians became the dominant power in the East.
Phoinicia with every prospect of success but having offended Agesilaus, he was deposed in a military revolt which gave the crown to Nekt-har-neb, or Nectanebo II., the last native king of Egypt. At this moment a revolt broke out. The prince of Mendes almost succeeded in overthrowing the new king. Agesilaus defeated the rival pretender, and left Nekt-har-neb established on the throne. But the opportunity of a decisive blow against Persia was lost. The new king, Artaxerxes III. Ochus, determined to reduce Egypt. A first expedition was defeated by the Greek mercenaries of Nekt-har-neb, but a second, commanded by Ochus himself, subdued Egypt with no further resistance than that of the Greek garrison of Pelusium. Nekt-neb, instead of endeavouring to relieve them, retreated to Memphis and fled thence to Ethiopia, B.C. 3401. Thus miserably fell the monarchy of the Pharaohs after an unexampled duration of nearly 3000 years, or as some think far longer. More than 2000 years have since passed, and though Egypt has from time to time been, except only in few instances, occupied by Asiatics, it was not until the very close of his reign that the Egyptians rose against his rule, and expelled the Persians, choosing as king Khabbash, whose name has been discovered in the Sarapeum. The revolt lasted but three years, and Xerxes I. suppressed it with severity. The Egyptians and their allies were now driven to the island of Prosopitis, and there besieged for eighteen months. At last Inaros was taken and put to death; Amyrtaeus, an Egyptian who reigned with him, fled to the marches, where he long maintained himself. Artaxerxes, after this serious revolt of six years, modified the administration of Egypt, recognizing Thanyura, son of Inaros, and Pausiris, of Amyrtaeus, as vassal kings. The government was, however, held by a Persian satrap; these were merely local princes.

An Amyrtaeus, probably son of Pausiris (Maspero, Hist. Anc., 562), revolted, and on the death of Darius II., B.C. 404, made Egypt virtually independent. He is in the one king of Dynasty XXVIII., Saita, whose successor, Naifaurus I., founded Dynasty XXXIX. B.C. 395. With him the monuments, silent since the rising of Khabbash, again give us information, and under the next dynasty show that the Sait art still lived in spite of the misfortunes the country had undergone. The Mendesians Nai faunaurs and Hakor are chiefly known for the part they took in aiding the enemies of Persia. Hakor was followed by Naifaurus II., and the sovereignty passed to Dynasty XXX. of Mendesians, the last native Egyptian line. The first of these kings, Nekhi-har-heb, or Nectanebo I., came to the throne when a Persian invasion was imminent, B.C. 378. Hakor had already formed a powerful army, largely composed of Greek mercenaries. This army Nekhi-har-heb intrusted to the Athenian Chabrias. The Persians, however, succeeded in causing his recall and in gaining the services of his fellow-countryman Iphicrates. The invading army consisted of 200,000 barbarians under Pharnabazus and 20,000 Greeks under Iphicrates. After the Egyptians had experienced a reverse, Iphicrates counselled an immediate advance on Memphis. His advice was not followed by Pharnabazus; the Egyptian king collected his forces and won a pitched battle near Mendes. Pharnabazus retreated, and Egypt was free.

Nekhi-har-heb was succeeded by Tachos or Teos, whose short reign was occupied by a war with Persia, in which the king of Egypt secured the services of a body of Greek mercenaries under the Spartan king Agesilaus and a fleet under the Athenian general Chabrias. He entered
wealthy, in Egyptian towns, where a Greek was rarely seen, and the king only appeared in the character of a Pharaoh to show respect to the religion of the country. The learned men of both races drew nearer together, and Greek speculation had its effect on Egyptian thought. The local, cultivated settlers were attracted by the native superstitions, and at last the Alexandrian was far more an Egyptian than a Macedonian.

On the division of Alexander's dominions, Egypt fell to the share of Ptolemy, son of Lagus and Arsinoe, a con-cubine of Philip's, whose son he was supposed to have been. Of all Alexander's generals he was the most far-sighted. Instead of amusing at the rule of the empire, he secured the least exposed province and employed its resources rather for defence than offence. One of his first acts was to divert the burial of Alexander from Macedon to Egypt. The body was taken to Memphis, but under Ptolemy's successor it was removed to Alexandria, so that the conqueror reposed in the city he had founded. His first conquest was the Cyrenaica (B.C. 322), a valuable province outside the field of the contests of his rivals, yet greatly useful for naval enterprises against them. Yet he did not declare himself for defence than offence. Cyrenaica (B.C. 322), and at last the Alexandrian was far more an Egyptian Ptolemy than a Greek

Invasion,亚运，and India was made a dependency, and the dominions of Seleucus. He returned to Egypt rich and powerful, and established a desert route from Coptos to Berenice on the coast which he had founded. He made war in Ethiopia, but according to his custom he was content to be on friendly terms with the Ethiopian king Ergamenes. His Egyptian conquests aimed at securing the purpose of securing a supply of elephants for war. An ambassador was sent to India. Thus the trade of Ethiopia, Arabia, and India was secured for Egypt, and continued to enrich it for eighteen centuries. Not less wisely Ptolemy made Alexandria, with the Museum and Library, the heart of the learning of Greece. Many cities were founded by him, or like Ptolemais in Galilee, refounded. In his long reign there was little expenditure but such as was calculated to enrich his empire. At his death his dominions equalled those of his father. He held Cyprus, much of the coast of Asia Minor, the Cyclades, and part of Ethiopia and Arabia. The Cyrenaica was only to be separated for the life of Magas. He twice married. His second wife was Arsinoe II, his full sister, whom he married in accordance with Egyptian rather than Greek notions. She was a woman of great beauty and character, and much loved by her husband. The character of Philopator is marked by the craft rather than the force of his father's, but he inherited to the full his love of literature and his love of pleasure, both undisturbed by warlike ambition. He is the last representative of the old Greek "tyranno's," whom Pandar has made known to us, rather than one of the restless "diadochi."

Ptolemy Euergetes, son of Philadelphia and Arsinoe I, by his accession, B.C. 247, reunited the Cyrenaica to the Egyptian empire. A quarrel between Egypt and Syria immediately broke out. The Syrian king Antiochus II. had married a daughter of Philadelphia. She was now put away, and, as well as Antiochus, murdered by her rival, his first wife Laodice, who set up her son Seleucus II. Ptolemy invaded Syria, which he speedily subdued, and then following the traditions of Egyptian conquest, he passed the Euphrates and reduced the whole of the eastern dominions of Seleucus. He returned to Egypt with vast treasures, including the statues of the gods which Cambyses had carried away, and which he restored to the temples. At sea he was equally fortunate, and the maritime territories of Egypt in the eastern Mediterranean were greatly enlarged. For a moment the old Egyptian Empire was again revived.

VII. — 94
in larger proportions, extending from the Thracian coast to Ethiopia, from Cyrene to the border of India. The eastern provinces speedily returned to the Syrian rule, and Ptolemy was content with a moderate accession of territory on that side. He, however, retained his Greek conquests and pushed far south in Abyssinia. Euergetes was not merely a warlike king. He cared for literature, and more than his predecessors endeavored to please the Egyptians. He is the first Ptolemy whose Egyptian structures are worthy of the wealth of the country. Art had lost its ancient delicacy, yet the sumptuous architecture of this age merits admiration as showing a new though somewhat false development of the ancient style. His reform of the native calendar, as recorded in the Decree of Canopus, is another mark of his wise interest in Egypt. He was fortunate in his marriage with Berenice II, who as queen of Cyrene is the first Egyptian queen who has the same regal style as her husband. Having reigned twenty-five years he left his kingdom to his son.

Ptolemy Philopator, who began to reign B.C. 222, immediately on his accession put his mother Berenice and others of his nearest kindred to death, and, leaving the management of the state to Sosibius, abandoned himself to luxury. Antiochus III., king of Syria, seized the opportunity to drive Ptolemy from all the eastern provinces. Ptolemy at length took the field himself in defence of Egypt, and defeated Antiochus at Raphia, where his success was greatly due to the courage of Arinnae, his sister and wife (B.C. 217). By this victory Cale-Syria and Phœnicia were recovered. Ptolemy returned to his former life, and Arinna was put to death. He left his kingdom, greatly weakened by bad administration and growing disaffection, to a child, Ptolemy Epiphanes. The other two Macedonian kings, Philip V. and Antiochus III., now allied themselves to despoil Egypt of the provinces. Everything but Cyprus and Cyrene was taken, and the Egyptian ministers, as it seems, saved the country by having called in the aid of Rome. The Republic had long been friendly to the Ptolemais, and nothing suited her policy better than a protectorate of Egypt. Accordingly M. Aemilius Lepidus was sent as regent to Alexandria, and Antiochus was commanded to evacuate what he had conquered. It was finally settled that Ptolemy should marry Cleopatra, daughter of the Syrian king, and that she should take Cale-Syria and Phœnicia. From this time Rome ruled Egypt with reference to her own eastern policy. The kingdom of the Ptolemais was not allowed to fall, but it was kept within the most moderate limits. Consequently the weak kings were supported and the strong kings thwarted in every way. Egypt could not rid herself of a bad ruler or enjoy the full advantage of a good one. The rest of the minority of Ptolemy was marked by a serious revolt in Lower Egypt, put down with great difficulty. In B.C. 196, when but thirteen or fourteen years old, the young king was crowned at Memphis, when the decree of the Rosetta Stone was issued. The place of coronation and the terms of the decree show a policy of conciliation towards the Egyptians which the revolt probably rendered especially necessary. The marriage of Ptolemy and Cleopatra I. took place B.C. 193-2, but the dowry was not handed over. Ptolemy continued true to the Romans in their war with Antiochus, but was not allowed to act as their ally, and gained nothing in the subsequent treaty. Another revolt broke out in Lower Egypt, and was cruelly suppressed, B.C. 185. Ptolemy perished by poison in B.C. 181, leaving two sons named Philomotor and Euergetes, who ruled Egypt in succession. Epiphanes inherited the weakness and cruelty of his father, and with him Egypt lost for a time her influence in the affairs of the world.

Cleopatra I., who like Berenice II. was queen as heiress, now became regent for Ptolemy Philometor, and ruled well until her death, about B.C. 174. The ministers then made war on Antiochus IV. (Epiphanes) for the disputed provinces. The Egyptian forces were defeated, Egypt invaded, and Ptolemy seized (B.C. 170). His younger brother, Euergetes II., with an audacious courage that marks his whole career, declared himself king of Alexandria, where he was accepted as such, and beheld his younger brother be sieged in vain, and Roman ambassadors interfered for his protection. Antiochus retired, leaving Philometor as king at Memphis. The two brothers now made terms, agreeing to a joint rule. Antiochus again invaded Egypt, and marched to Alexandria, but was forced to retire by the resolution of a Roman ambassador, M. Popillius L scanus (B.C. 168). From this time Egypt was more than ever in the hands of the Romans, and in consequence of the manner in which Philometor had yielded to Antiochus while Euergetes had resisted his pretensions and depended on their support, we find them constantly aiding Euergetes, whose ability and moderation in justice in treatment of his subjects and by a perfidious and cruel disposition. It was not long before Euergetes succeeded in driving Philometor from Alexandria. The fugitive went to Rome B.C. 164, and the senate agreed to reinstate him. Euergetes was spared by his brother, and the Roman deputies obtained for him the kingdom of Cyrene, where he occupied himself in raising the young king, and attained Egypt, assisted by the active support of Demetrius I. of Syria and the unjust diplomatic aid of the Roman senate. Philometor had the courage to oppose his brother, who invaded Cyprus with Roman ambassadors ordered to settle him in the government of the island. Philometor defeated and took him prisoner, but again spared his life, and left him the kingdom of Cyprus (B.C. 164). The Romans did not interfere with this settlement.

The part Demetrius I. had played in the war in Cyprus led Philometor to take the side of the usurper Alexander I. (Balas), to whom he gave his daughter Cleopatra to wife (B.C. 160). When Demetrius II. endeavoured to recover his father's kingdom Philometor advanced to the support of Alexander, but thinking him treacherous, he turned his arms to the aid of the legitimate king. Rapidly subduing the country, Ptolemy entered Antioch and was hailed king of Syria, to the crown of which he had a claim as descended maternally from the Seleucid line; but he admitted the higher right of Demetrius, whom he aided in repelling an invasion by Alexander. In a decisive victory Ptolemy was thrown by his horse and mortally injured (B.C. 146).

It was in the reign of Philometor that Oianis founded the temple at Onis in Egypt, which tended to increase the importance of the Jewish colonies and to separate the Alexandrian from the Palestinian school.

With this king the power of Egypt finally fell. He was the last Ptolemy who had the capacity to rule amidst the growing difficulties of the time. In his wars he showed courage and generalship, in his dealings with Rome caution and decision, in his rejection of the Seleucid diadem moderation and justice, in his administration of the kingdom and his subjects an extraordinary clemency and humanity.

Cleopatra II., the sister and widow of Philometor, put their son on the throne. Euergetes at once marched from Cyrene to Alexandria. The Romans as usual took the part, and stopped the war on the condition that Euergetes should marry his brother's widow. The young king was instantly put to death. Ptolemy reigned as he had begun: Alexandria was depopulated by his cruelties, though the rest of Egypt seems to have fared better in consequence of his want of ambition. He divorced Cleopatra II. to

1 There is difficulty as to his name. In Egyptian documents Emperor precedes or follows Philometor (Lepova, Bert. Akad. 1852, 454, 1853, 384); but in a Greek inscription in Cyprus the later name is stated (Hogg, J., "Insera. from Cyprus," R. S. Lit., 2 ser., vol. xx at 397, sqq.).
merry his daughter, his niece, Cleopatra III. In B.C. 130
he was driven out of Egypt by a revolt, and Cleopatra II.
became queen. In revenge he put to death their son.
Cleopatra having asked the aid of Demetrius II., Ptolemy
was recalled, B.C. 127, and for the rest of his reign adopted
a more conciliatory policy. He engaged in war against
Demetrius II., and supported the usurper Alexander II.,
against whom he subsequently turned, apparently with
reason. The reconciliation with the Seleucidae led to the
recall of Cleopatra II., with whom Ptolemy now reigned.
He died B.C. 117, in the fifty-fourth year from his first
accession. This king, the worst of the Ptolemies, as
Philometor was the best, is significantly known by the
nickname Physcon, or Fat-paunch, but he was also called
by his subjects the Ill-doer, Kakergetes, instead of the Well-
doer, Energetes. Some of his latest coins present, instead
of the idealized head of Ptolemy, the founder of the line,
bloated and cruel features which can only be those of
Physcon. His one good quality was a hereditary love of
lepers.

Cleopatra III., surnamed Cocos, widow of Energetes and
heiress of Philometor, succeeded, and, in deference to the
popular will of the Alexandrians, associated with her
Ptolemy Soter II., surnamed Lathyrus, or Lathurus, her
elder son, instead of Ptolemy Alexander I., the younger,
whom she preferred. They ruled together with little con-
decord, and at length Cleopatra expelled her colleague, who
had been the real sovereign, and recalled Alexander from
Cyprus, where he had already ruled independently for
seven years (B.C. 107). Cyrene was probably lost to Egypt
about this time. Physcon had left this kingdom to his
base son Ptolemy Aphon, who is generally supposed to
have at once succeeded. The coins, however, show that
the latest Cyrenac coinage of Physcon was continued by
Lathyrus. Cleopatra III. now ruled with a stronger
authority, but by degrees Alexander gained the upper
hand, and ultimately dissensions arose which ended by his
causing her death (B.C. 89): this occasioned troubles which
lost him his throne, and brought about the recall of his
brother (B.C. 89). During the interval Lathyrus had ruled
in Cyprus, and both brothers had engaged on opposite sides
in the wars of the Seleucid princes. As king of Egypt,
Lathyrus died (B.C. 81). He appears to have been weak and
cowardly, with some qualities of a politician and general. He left one legitimate child, a daughter, Berenice III., who succeeded him. Her step-son, Alexander II., son of Alexander I., came from Rome as Sulla's candidate, and married her. The nuptials were almost immediately followed by the murder of the queen by her husband's order, and his deserved death in a popular tumult which was thus excited (B.C. 80).

In default of legitimate issue, two bases sons of Lathyrus now shared the Egyptian dominions, the elder, Ptolemy Neus
Dionysus, surnamed Auletes, the flute-player, taking Egypt,
and his younger brother Ptolemy acquiring Cyprus. Auletes
inherited the vices without the ability of Physcon, and
having spent great sums in obtaining the recognition of the
senate, who probably would not readily part with the claim
based on the legacy which either Alexander I. or II. had
made to the Romans, he wearied the patience of his subjects by heavy taxation, and was expelled by the Alexandrians B.C. 58. His wife Cleopatra V. and daughter Berenice IV. now reigned together, but, on the death of the elder, the younger became sole queen. Berenice was twice married, first to Seleucus, a pretend Seleucid,
whom she put to death, and then to Archelaus. With the
support of Gabinius, proconsul of Syria, Auletes at last
recovered Egypt, B.C. 55. He punished his daughter with
death, and in B.C. 51 his troubled reign came to an end.
At this time his family consisted of two sons and two
daughters,—the famous Cleopatra and Arsinoe, all of
whom in turn exercised regal power, three in a generation.

Ptolemy, the elder son of Auletes, and Cleopatra VI.,
his elder daughter, succeeded in accordance with their
father's will, which the Roman senate ratified. In B.C. 48
he had expelled Cleopatra, who fled into Syria. Advancing to conquer Egypt by force of arms, she was met by
her brother's forces near Fulanium. Here it was that
Pompey, after the ruin of his cause, was assassinated by
order of Ptolemy's ministers as he sought the king's protection.
Cesar, following Pompey, reached Alexandria. Here Cleopatra, giving up her idea of war, made her way to Cesar and secured his interest. After a struggle with
the Egyptian ministers, who almost succeeded in overpowering
Cesar's small forces, and who ultimately had the
support of young Ptolemy, who escaped from the Romans,
the Egyptians were defeated and the king drowned (B.C. 47).
Cleopatra now became queen, associated with her son
Ptolemy, the elder son of Auletes, and Auletes, her
elder son, instead of Ptolemy Alexander I., the younger,
whom she preferred. They ruled together with
a phalangian king, the younger Ptolemy. In B.C. 45 she went to Rome with her brother and young Ptolemy Cesar, her son by the dictator, wishing to be acknowledged Cesar's wife, and
that the boy should reign as his heir. Next year Cesar
was murdered, but by his will his nephew Octavian became
his heir, Cleopatra's son, his only surviving child, being neces-
sarily set aside. The queen determined to secure for her son
Egypt at least, and made away with her unfortunate brother. She next appears when, after the battle of Philippi,
the triumvir Antony made his progress through Asia Minor.
It was necessary that the queen of Egypt should
consult the ruler of the Eastern world. Cleopatra resolved
to govern him. As Cesar seven years before, Antony
now was instantly captivated by the Egyptian queen.
She was past thirty, but if her beauty had waned her wit
had grown. Her portrait on her coins is that of a woman of
intellect and charm, not of beauty. A broad head with
wavy hair, an aquiline nose, large deep-set eyes, and a full
esquint mouth, is supported by a long slender throat.
To these personal qualities she added a mind singularly
cultivated, ready discourse in several languages, and,
what that so often lacks, as ready wit. She took Antony
to Alexandria and governed the East for him. While
her power waxed his waned. Asia Minor was overrun by Q. Labienus at the head of a Parthian army, and
Palestine and Phœnix by another led by Pacorus, the Par-
than king's son. In Italy Antony's adherents were routed.
He now resolved to attack Italy itself, and a great
war was only averted by the armies, which forced the generals to conclude a peace (B.C. 40). Octavia, his rival's
sister, was given in marriage to Antony, and for three
years Cleopatra lost her power. In B.C. 36 Antony deserted
Octavia and returned to Alexandria and the Egyptian
queen. With the exception of an unsuccessful Parthian
campaign and an inglorious Armenian one, Antony effected
nothing. He was amused by the luxurious life of
Alexandria, and, while Cleopatra maintained her Egyptian
rights and ruled with Ptolemy Cesar, she shared Antony's
government of the East, appearing as queen with him as
triumvir upon the coins of Antioch. In B.C. 32 Octavian
declared war against Cleopatra, and Antony took his
revenge by divorcing Octavia. Then followed the conflict
in the Adriatic for the world's empire, in which Antony's
old military skill failed him, and Cleopatra, leaving the
battle, perhaps through a woman's fear, drew him away
also (B.C. 31). Arrested at Alexandria, Cleopatra allowed
more energy than Antony, and, when Octavian reached
Egypt, more policy. Antony, on the false news of the queen's death, stabbed himself, and Cleopatra, finding October, she contrived to make her walk in his triumph, perished by her own hands in some unknown way. Thus Egypt became a Roman province, b.c. 30. The young Ptolemy Caesar, in spite of his double claim, perished by the command of Octavian, but the beautiful Cleopatra, Antony's wife, who obtained the whole of the empire by the cleverly taken by his divorced wife Octavia, brought up with her own children, and married to a kug, Juba II. of Mauretania. With their son Ptolemy, whom Caligula put to death A.D. 40, this great line came to an end. Its genius ended with Cleopatra. The decline of the Romans tended to give the moderns too low an estimate of her abilities. When we see what Egypt was under Augustus and under her we are astonished to perceive how much she accomplished by her management of Caesar and of Antony.

After all the other independent states had been absorbed by Rome, Egypt was raised from a more protected province to be once more a kingdom, and at last Alexandria became again a seat of empire. But the task Cleopatra set herself was beyond accomplishment; the more she turned Antony into an imperial ruler the less could he control the Roman armies by which he governed. Thus the fabric she had raised was rotten at the base, and when her fall it disappeared. The history of Egypt under the Romans being that of a province, and the most interesting events matter of ecclesiastical history, may here be told very briefly. Worn out by the cruelty and avance a series of bad rulers, the country must have wel-

The country, whose school of thought was in some respects ready to welcome it. From them it rapidly passed to the Greeks. Ultimately, the tolerant policy of Christianity came with special fitness to a subject race. The history of the Coptic version has yet to be written. It presents some features of great antiquity, and, unlike all others, has the truly popular character of being written in the three dialects of the language. Side by side then grew up an Alexandrian Church, philosophic, disputative, ambitious, the centre of Christianity, and an Egyptian Church, ascetic, contemplative, mystical. The two at length influenced one another; still we can generally trace the philosophic teachers to a native rising, the mystic to an Egyptian.

Celsus, in revenge for an affront, massacred the population of Alexandria. Under Decius the Christians again suffered from persecution. When a German broke in the weak reign of Gal-

VA.
The success of Heraclius restored Egypt to the Empire and for a time it again received a Greek governor. The Monophysites, who had taken advantage of the Persian occupation, were persecuted and their patriots expelled. The Arab conquest was welcomed by the native Christians, but with it they ceased to be the Egyptian nation. Their language is still used in their churches, but it is no longer spoken, and its literature, which is wholly ecclesiastical, has been long unproductive.

The decline of Egypt was due to the purely military government of the Romans, and their subsequent alliance with the Greek party of Alexandria which never represented the country. Under weak emperors, the rest of Egypt was exposed to the raids of savages, and left to fall into a condition of barbarism. Ecclesiastical disputes tended to alienate both the native population and the Alexandrians. Thus at last the country was merely held by armed force, and the authority of the governor was little recognized beyond Alexandria, except where garrisons were stationed. There was no military spirit in a population unused to arms, nor any disposition to patriotic or arbitrary persecuting rule. Thus the Muslim conquest was easy.

In the year 639 of our Era, or the eighteenth of the Flights, Egypt was invaded by the Muslims, under the celebrated 'Amr Ibn-El-As (or El-Asee). Entering the country from Syria, at the head of only 4000 men, he passed through Egypt and took it after thirty days. His town was considered the key of Egypt on the Syrian frontier, and its capture was, therefore, an important advantage, which opened the country southwards to the Arab general. He marched thence to El-Yens, the ancient Heliopolis, where he found the Greeks collected in force, and compelled by John, the governor of El-Makreezee, or rather John the Mukowkl8, or Qureyy the Mukowkis, the governor of Memphis, a native Egyptian. They offered a vigorous defence, but were put to the rout, and 'Amr advanced to the banks of the Nile and laid siege to Egyptian Babylon, a fortress of great strength, and garrisoned by a Roman legion. Here he received two reinforcements of 4000 Muslims each, and after a protracted siege of seven months he took the place by assault. In an enemy's country, and beyond the frontier, and country from town, was celebrated 'Amr Ibn-EI-As (or EI-Makreezee), the symbol of the governor of Egypt under the Byzantine Empire, as the prayer and deliverance of the faithful in time of necessity, and the seat of government removed thither. The site is without the walls of modern Cairo, and is marked by extensive mounds of rubbish.

In a.d. 652, the son of Tooloon, a Turkish slave who held a high office at Bagdad, was appointed governor of the province of Murs by the caliph Abd-al-Rahma, and two years after that of Alexandria also, by his successor El-Muhortede. His temporal allegiance to the caliph soon became merely nominal, and he was virtually sovereign of Egypt, but at the same time he endeavoured to avoid a complete rupture by continuing the prayer for the Princes of the Faithful in the mosques, and the mention of his name on the coins which he struck. Later in his reign, however, he forbade the mention of the caliph's brother and colleague El-Mowaffik in the prayers and gave himself the title of 'Amr Ibn-El-As. By permission of Omar, and El-Mukowkis, speaking of Pompey's Pillar, says, "It is said that this pillar is one of those which stood in the port of Alexandria, and that his academy contained a library which 'Amr Ibn-El-As had begun to adorn by direction of Omar." See Englishman in Egypt, vol. i, 60, seq.
of his own wealth and magnificence, still the largest mosque of Cairo, and, as presenting the study of the pointed arch, notable in the history of architecture. The reign of this vigorous and wise prince was remarkable for prosperity at home and conquests abroad. He took Baack, and in Syria in 274, captured Damascus, Hums (Kamesa), Hamah, and Aleppo; after which he proceeded to Antioch, and the governor refusing to surrender, he took that city by storm. He then advanced towards Damascus, but the supplies failing he was compelled to retire. About five years later, Lu-lu, his deputy and governor of Aleppo and other towns in Syria and in Mesopotamia, revolted and concluded a league with El-Muwaffak. It was apparently after an expedition against this rebel that Ahmad died, in the year 270 (A.D. 884).

During the latter years of his reign, he had subdued a plenty of life which had distinguished his youth, and had given himself up to boundless luxury. At his death, there was found in his treasury ten million gold pieces, and his establishment was discovered to consist of 7000 mounted muleteers, 300 packed horses for his own use, a body-guard of 24,000 slaves, besides 6000 asses and more than 10,000 camels, and 100000 horses. By what appears, the revenue necessary to maintain such a household was raised some idea may be formed, when it is stated that at the time of his death, the revenues of his kingdom were confined in Arab's present year.

Khumarraweyh, on the death of his father, was appointed his successor by the army, he being then twenty years old, and he inherited from him in an extended race of Euphrates to Syria in which his army guarded the vassal, although he himself, never having seen a battle before, fled the scenes of action in a panic, drawing a large part of his troops after him, and the latter, pursued the rambling policy of his father, and making peace with the caliph in 278 he not only put the latter's name with that of his brother El-Muwaffak in the public practice, but equally omitted his own; though it must be allowed he did not pursue the same servile course in his conge. On the accession of El-Muwaffak in 279, Khumarraweyh continued his policy and office and offered his daughter Kafi-en-Nedah (Wedwoura) in marriage to the caliph's son. In 283 he made an invasion into the Greek territory, and died at Damascus. It is said that he was fearful of assassination; to avoid which he had trained a man to guard him who slept on his bed of quicksilver. His fate was unjustified; for he was put to death by his women, or according to some by his eunuchs.

His eldest son, Geysh Abul-As'akir, not yet fourteen years old, succeeded him. This prince was killed in less than eight months, his youth, which rendered him unfit to govern, occasioned his fall; for he was seduced from his ascetic life by his father, and associated with none but worthless men. He was succeeded in 283 by his brother Hakoon, the principal events of whose reign were a great desert settlement, a navigation in Egypt, and a treaty which he concluded with the caliph, by which the provinces of Aswan and Kinnernoo were ceded to him and the annual tribute from Egypt was fixed at 450,000 dinars. He reigned upwards of eight years, but gave himself up to pleasure, and as some say, he was put to death in 292 by his uncle Shyibain and Adoo, sons of the founder of the dynasty, the former of whom succeeded to the government. In the meantime, at the instigation of the generals of Hakoon, Mohammad Ibn-Suleyman, a scion of Lu-lu, advanced upon Egypt with a numerous and heavily armed army. Shyibain went forth to meet him with all the forces he could muster, but numbers of his troops deserted to the invader, some to support their sovereign, others to avenger the former, in the year 345, a great fire occurred in El-Fustat, which destroyed 1700 houses and much merchandise; the caliph at once sent 356, and we have no account of the desolation in Egypt. Three years afterward, El-Muktefese wrote to him complaining of the rise of the Memluk dynasty, of which he was the head, and El-Muktefese immediately repaired to him to seek for aid of those who were in Egypt, of which the caliph was too timid to avail himself. About this time, also, he conducted a war with various success against Seyf-ed-Dowleh the Hamidotes, who had attacked Syria. He died at Damascus in 345 (A.D. 946), in the 56th year of his age, and was buried, as were his sons, the mosque of Omar at Jerusalem.

Of El-Ikhshad's two sons and successors, Abul-As'akir Ongoon (who died in 349), and Abul-As'akir 'Alee, little is known, their mother Kaffi, a black eunuch, was the regent of the former, in the year 345, a great fire occurred in El-Fustat, which destroyed 1700 houses and much merchandise; the caliph at once sent 356, and we have no account of the desolation in Egypt. Three years afterward, El-Muktefese wrote to him complaining of the rise of the Memluk dynasty, of which he was the head, and El-Muktefese immediately repaired to him to seek for aid of those who were in Egypt, of which the caliph was too timid to avail himself. About this time, also, he conducted a war with various success against Seyf-ed-Dowleh the Hamidotes, who had attacked Syria. He died at Damascus in 345 (A.D. 946), in the 56th year of his age, and was buried, as were his sons, the mosque of Omar at Jerusalem.

Hittito, with few exceptions, the most notable of which are the reigns of Ibn-Tooool, Khumarraweyh, El-Ikhshed, and Kaffo, the Muslim rulers of Egypt had not much benefited the country, or rescued it from thearchy and troubles in which it had become involved under the Lower Empire. But the incidents of the time are so little known that they have been deemed worthy of more notice in this article than any other of those of Ibn-Tooool, which were in favor with the caliph. In 356, El-Muktefese wrote to him asking for help, as well as other learned men, he rewarded with magnificent presents. On his death in 357, internal dissensions respecting the succession of Ibn-Tooool, a son of 'Alee, presented a favourable opportunity to the Fatimite caliph to renew the often-repeated invasions of Egypt.

The data of El-Ikhshed's reign is not much benefited by the country, or rescued it from thearchy and troubles in which it had become involved under the Lower Empire. But the incidents of the time are so little known that they have been deemed worthy of more notice in this article than any other of those of Ibn-Tooool, which were in favor with the caliph. In 356, El-Muktefese wrote to him asking for help, as well as other learned men, he rewarded with magnificent presents. On his death in 357, internal dissensions respecting the succession of Ibn-Tooool, a son of 'Alee, presented a favourable opportunity to the Fatimite caliph to renew the often-repeated invasions of Egypt.
But, while the conditions were being ratified, the Ikhaburees prevailed on the people to revoke their offer, and the ambassadors on their return were themselves compelled to seek safety in flight. Gohar pushed forward. Before El-Geesheh a fierce battle took place; several days were passed in skirmishes, and at length he forced the passage of the Nile a few miles south of that town. Instead of his troops, the Ikhaburees offered him a strong resistance, the greater part were dead on the field, and the remainder, taking what valuables they could carry off, fled for their lives. El-Geesheh was now brought to the terror of the inhabitants and the women of the fallen dynasty, and to the honour of the African general it is related that they were satisfied and the city was possessionally occupied. The dominion of the rest of Egypt was secured by this victory, and all the Hipsi, including the holy cities, and the Yemen, specially acknowledged the authority of the Fatimite El-Mo’izz. In the year 359 Syri had also added to his dominions, but shortly after was overrun by the Karmatrce (Carmathians), the troops of El-Mo’izz met with several reverses, Damascus was taken, and those lawless free-booters, joined by the Ikhaburees, advanced to ‘Yen-Shema. In the meanwhile, Gohar had fortified El-Kahureh,1 or Cairo (the new capital which he had founded immediately north of El-Fustat), and taken every precaution to repel the invaders, a bloody battle was fought near El-Kahureh, bringing with him the bodies of his three predecessors and vast treasure. El-Mo’izz reigned about two years in Egypt, dying in the year 365 H.S. He was, as a warlike and ambitious prince, but, notwithstanding, he was especially distinguished for justice and was fond of learning. He showed great favour to the Christians, especially to the Bishop of El-Ahmun. In the first days of his reign he entered Cairo on the 9th, before the city walls, without any decrees result. On the following Sunday, however, Gohar obtained a great victory over the enemy, and surrounded him more complete than any invasion, and suffered, and the camp beggar and fell into the hands of the conqueror.

The earnest solicitations of his lieutenant, who had ruled Egypt both ably and justly, with almost absolute authority, El-Mo’izz at length determined to remove his court to his new kingdom, and El-Kahureh was entered, and from this place to the life of the city, Gohar, when he founded that city, built the great mosque named El-Asur, the university of Egypt, which to this day is crowded with students from all parts of the Muslim world. The principal event of his reign in Egypt was the second invasion of Hasam, the Karmatean of Damascus. The enemy, as on the former occasion, reached ‘Yen-Shema, but now he gained more advantage over the African troops. Although he was twice defeated in different parts of Egypt, and at last turned back, in the advance, the capital was closely besieged by him, and its defenders were driven across the river. Thus surrounded, El-Mo’izz recurred to his earliest course of action, and succeeded in breaking Hassan Ibn El-Carnab (who, with a body of the tribe of Teu, fought with the Karmateans) to cultivated an ally of Hassan, before mentioned, had made himself master of Ramleh, and from this capital the regis might exercise his influence on her house, incurred her displeasure, and being fearful for her life, she secretly set forward, and by night concerted measures were taken by the chief of the guard, who very readily agreed to her plan. Ten slaves, bribed by 500 dinars each, having received their instructions, went forth on the 20th of the 1st of Ramada, in the year 370, to the city of Cairo, where El-Hukum, unattended, was in the habit of riding, and waylaid near the village of Huwm, where they put him to death. He was succeeded by his son, Edh-Dhibar (commonly pronounced El-Zahir) ill-lah Abu-Ibns ‘Alee, who ruled with justice and moderation for about sixteen years. In 414 Alepp was taken by Salih Ibn-Mardas, and although he was defeated and slain by an Egyptian force sent against him, a sheik-ed-Dowleh, yet retained possession of that city. But, while Hassan, of the tribe of Teu, before mentioned, had made himself master of Ramleh, and from this capital the reign occupied a long period, rendered remarkable by the unparalleled troubles which befell Egypt. It commenced prosperously with the defeat and death of Shihel-ed-Dowleh. The result of this was, that El-Mo’izz was again defeated and compelled to fly, this event, which occurred in the year 368, relieved Egypt of a terror, an ally of Hassan, by name Abd-Allah Ibn-Udoed-Allah (formerly governor of Syria under Kafour), and obtained for the arms of El-Mo’izz various successes in Syria.

El’Aziz Abu-Mansoor Nishr, on coming to the throne of his father, immediately dispatched an expedition against the Turkish chief El-Efkeeen, who had taken Damascus a short time previously. Gohar again commanded the army, and pressed the siege of that city so vigorously that the enemy called to their aid the Karmateans. Before this united army he retired by little and little to Accele, where he prepared to stand a siege; but being reduced to great straits, he purchased his liberty with a large sum of money. On his return from this disastrous campaign, El’Aziz took up his quarters in Damascus and sending the enemy at Ramleh was victorious after a bloody battle; while El-Efkeeen, being betrayed into his hands, was with Arab magnanimity reserved with him, and when he had gained a fair victory, the army returned in silence. El’Aziz followed his father’s example of liberality. It is even said that he appointed a Jew his vizir in Syria, and a Christian constable in the house of himself. These acts, however, cost him his life, and a popular tumult obliged him to disgrace both those offices. After a reign of twenty-one years of great internal prosperity, he fell in a battle near the blacks and Turks, both of whom had become numerous in Egypt. The former were succoured by the mother of El-Mutassar, whereafter a remarkable event, by which the immediate cause was more closely as usual. El-Bessacaree, a powerful Turkish chief excommunicated an exiled bishop in that city, had fallen into disgrace, and received supplies of men and money from the caliph of Egypt, and while the Scekeerei sultan Tshgri-Beg espoused the cause of the ‘Abbasieh caliph, he has been turned, and defeated El-Bessacaree, and sent Tshgri-Beg. El-Bessacaree entered Bagdad, in which the combat continued to rage; and the unfortunate El-Mutassar was slain, and the succeeding to the throne of El-Kahureh. El-Mutassan was solemnly declared Prince of the Faithful, and the insignia of the legitimate caliph was sent to El-Kahureh. The success of El-Bessacaree, however, was but transient; Tshgri-Beg had, in the meantime, defeated and killed his brother Ibraheem; he then entered Bagdad in Islam-kaadah 451, and surprised a force against El-Bessacaree, who fell in a battle near El-Korof.

A persecution of the Christians of Alexandria occurred about this time; and in 454 commenced a deplorable state of things between the blacks and the Turks, both of whom had become numerous in Egypt. The former were succoured by the mother of El-Mutassar,
His son El-'Amir bi-ahlami-Llah Abou-'Ameen Mansoor came to the throne at the age of five years, and until his death in 487, the government was conducted by El-'Afal. The first act of the caliph, however, on taking it into his own hands, was to put his minister to death, and appoint his uncle as his successor. The caliph was an able man, having reduced many of the principal coast-towns in Syria, mediated the conquest of Egypt, and crossed the frontier, but were encountered from the prosecution of these designs. El-Hafidh, whose death took place at El-Areesh, on his way back to Jerusalem. El-'Amir was put to death in 524. At the town of El-Geesh, it is said by partisans of El-Afdal, whose son then usurped the entire government, setting up, as caliph, El-Hafidh bi-deen-I-Llah Abd El-Messaad, a grandson of El-Mustansur (El-Amir having left no male issue), but without the usual ceremonies of installation. This vizir, Abou-'Ameen Ahmad, even forbade the mention of El-Hafidh in the public prayers, and inserted his own name in his stead. He perished in a popular tumult, raised by his extremities and arbitrary rule, and El-Hafidh was duly declared caliph and received the oaths of allegiance. After the death of Ahmad, he succeeded to the seat, but his reign was equaly refractory, and the people abandoned him, being exhausted, the worst of war, were depopulated, and that half the inhabitants of the town were dispersed by these bands. But the very portion of the population that inhabited the city, was given up to his oppression and arbitrariness. At length, his finding his power failing, gathered together the wealth he had amassed and fled to Syria, where he fell into the hands of the Chechen, and disposed of all that he had and detained him a prisoner. Eventually he was given up to Taise and cruised over the gates of the palace.

These events were occurring in Egypt, Syria was in a continual state of anarchy and war. A distinguished general, the ever Egypt, the Chechen, who by his oppression and cruelly miserly rendered El-Afdal, by nature benevolent and wise, as tyrannical as himself. He was assassinated after a year by the secret orders of the enemy, and succeeded in his place. At this time the well-known Shawar was governor of the B FIXED (or Upper Egypt), a post next in importance to that of prime minister. During the last three reigns the vizirs had been rapidly increasing in power; and the annals of the period are entirely occupied with the rise and fall of potent grandees, all eager for a post which conferred on its possessor the supreme authority. At length, in the reign of this unfortunate prince, they concerted the ruin of the dynasty and overwhelmed themselves in its fall. In 538 El-Afdal dispossessed Shawar of his government, and the latter had immediate recourse to arms, and marched against his enemy, succeeded in putting him to flight. He then constituted himself vizir, and compelled to fly to a more powerful rival, Ed-Dugham. Neor-Ed-Deen (Norouz), the sultan of Damascus, received the fugitive, assumed the crown; and in the course of the next year invaded an army to Egypt, under the command of Asad-el-Deen Sherkook, to remit him. In the meantime Ed-Dugham had been busy putting to death the great men of the empire; and having thus weakened his power, he offered but a feeble resistance, was overthrown in a battle near the Boukhay Salcic, on the S. of El-Kursh and Shawar was restored. No sooner, however, was this effected, than he forgot the engagements into which he had entered with Norouz, and threw off his allegiance to him. Sherkook retired to the Sherkook, and occupied the town of Bileba, and thence threatened Shawar. In this position of affairs the latter had recourse to the Crusaders, who willingly responded to his call, and Arsac, king of the Crusaders, assembled a formidable force. With these allies, Shewar beseiged his former protector in Bileba, until, hearing of Norouz's successes over the Franks in Syria, the sultan passed a peace, and permitted Shewar to withdraw from Egypt. About two years later, Norouz, determined on punishing the treachery of Shewar, assembled an army, and sent Sherkook into Egypt, beseiged by his nephew, the famous Saladin. Shrewar again sought to strengthen himself by an alliance with Arsac, from whom he received the first intimation. Appreciation of this knowledge of his movements, Sherkook changed his course from Bileba, entered the valley of the Nile at some distance above Cairo, and after marching northwards to El-Geesh. Here he endeavoured to raise the people against Shewar and his Frank confederates; and had in some measure succeeded when the superior forces of the enemy
compelled him to retreat southwards as far as El-Babyn, near Ashmoenyn, where he rallied an engagement, and gained a considerable victory. This success renewed to the weakness of the greater part of Egypt, and Alexandria itself fell into their hands. Saladin was placed in that city with a numerous garrison, and his uncle appointed to be their vicar, and the rest of Egypt. The Crusaders, however, at once closely invested Alexandria, and so pressed the town for three months, as to oblige Sheerkook to come to its relief. An honorable compromise was effected, and he himself fled alone on a dracary. After this, however, he gained some partial advantages over the Christians, till a terrible famine induced him two years later to conclude a truce with the king of Jerusalem and to retire to Egypt. In the year 576 he again entered Syria and made war on Kiiy-Aralin, the Seljook sultan of Anatolia, and on Leon, king of Armenia, the Cilician-Armenian kingdom, both of whom he forced to make terms of peace. Not long after his return, Saladin departed from Egypt (A.H. 578) to prosecute a war with the Crusaders in which neither side desired peace. Their hostility was aggravated by the following circumstances. A vessel bearing 1500 pilgrims had been wrecked near Damietta, and its passengers captured; and to the remonstrances of the king of Jerusalem the sultan replied by complaining of the constant forays made by Renaud de Châlillon. At this time the latter turbulent chief undertook an expedition against Eyleh, and for this purpose constructed boats at Karak and conveyed them on canals to the sea, but this flotilla was repulsed, and the siege raised by a fleet sent thither by El-Fard ("Saphedm"), the brother of Saladin, and then his viceroy; and a second attempt was still more unfortunate, the Christian captives on that occasion were sacrificed in the valley of Min. Having threatened Karak, Saladin encamped at Tiberias, and ravaged the territory of the Franks; he then besieged Beyroot, but in vain; and thence turned his arms against Mesopotamia and subdued the country, but the city of Mosul successfully resisted him. In the meanwhile, the Crusaders contended themselves with miserable forays across the enemy's borders, and made no serious preparations for the return of their redoubtable antagonist. The latter, having been almost everywhere successful in Mesopotamia, took Tell-Khalih and 'Eyn-Teb in Syria and obtained possession of Aleppo; he again besieged Karak, ravaged the territory of Samara, and later received the fealty of the lord of Mosul, but not the keys of the city. In the year 583 (1186 of our era) war again broke out between Saladin and the Crusaders. The sultan had respected a truce into which he had entered with Baldwin the Leper, and Renaud to the advantage of the Crusaders. The capture by the latter of a large caravan enraged Saladin, who despatched orders to all his lieutenants and vassals, summoning them to assemble in the "Holy War." He marched (A.D. 1187) from Damascus to Karak, and there laid close siege to Renaud, at the same time a large body of cavalry under the command of his son, El-Afdal, advanced on Nazareth; and here a body of 130 Knights Hospitalers and Templars, seconded by a few hundred foot soldiers, and encouraged by the heroic Jacques de Maile, marshal of the Temple, by their devotion immortalized their memory. Only the Grand Master of the Temple and two of his knights escaped from the unequal struggle. Soon after, Saladin approached in person at the head of an army of 80,000 men; and the Christians with their whole force encountered him on the shore of the Lake of Tiberias. The result of the battle which ensued was the heaviest blow which had yet fallen on the Crusaders. Weakened by thirst, shaken by the flight of a part of their troops on the second day of combat, and overwhelmed by numbers, the knights fought with desperate courage, but at last the prisoners were Guy VII. — 95
de Luigian (the king of Jerusalem and successor of Baldwin), with his brother and Renaud de Chatillon. The success was almost incredible; and the massacre of many of them is an unspeakable stain on the glory of the generally merciful Saladin. Tiberias, Ptolemaus (Acre), Nablus, Jericho, Ramleh, Caesarea, Arsur, Joppa, Beyrouth, and many other places successively fell into the hands of the conqueror. Tyre resisted his armament; and other strongholds (among others Karak) were surrendered on favourable terms, and the fall of Jerusalem crowned these victories. The great clemency of Saladin on this occasion is chronicled by Christian historians, though it is but slightly mentioned by the Muslims, who took offence at the mercy shown to the enemies of their faith.

After these events Tyre was again besieged, and when about to capitulate was relieved by the arrival of Conrad, son of the marquis of Montferrat. The valiant defence of the town wearied Saladin, who turned his arms against Tripoli; but here he met with no better success. Bologna, prince of Latium, and at that time protector of Tripoli also, was, however, glad to obtain a truce of eight months; and some strongholds (among others Karak) were taken. But now the fortune of war turned against the sultan. The ever-memorable siege of Acre, the signal victory over the sultan in the hands of the crusaders, which is an important and useful lesson against the princes of his family successively governed that country, and the enuch Karakooch, who also defended Acre, held a large share of authority.

On the death of Saladin, his extensive dominions were divided chiefly among his sons, and Egypt fell to the lot of one of them, El-Melik El-Aziz Imad-ed-Deen Othman. The grandees supported his claim to the throne, and he proved himself worthy of their choice. In conjunction with El-Aziz, we find him warring against the leaders of the Fourth Crusade. He reigned nearly six years, and was succeeded (in 595) by his son El-Mansoor Moham­med, whose uncle El-Afial was committed to prison. The government of Damascus and the assumption of the sultan. Having dethroned El-Mansoor, El-Afial formed an alliance against the sultan, with the ever-memorable siege of Acre, the signal victory over the sultan in the hands of the crusaders, which is an important and useful lesson against the princes of his family successively governed that country, and the enuch Karakooch, who also defended Acre, held a large share of authority.

Damascus, and, in consequence of this alliance, Jerusalem, with its circuit, and the places between it and Joppa and Acre, Nazareth and the seven other cities of Galilee, with all the spread of coasts, was ceded to Frederick on the 20th of Feb. 1229. Between these two monarchs, exalted to the most friendly relations, presenting a curious spectacle in the midst of the intrigues and hatred of their subjects for each other, and endangering their popularity and even their lives, after various expeditions against his brother and his successors, Elyoob gained possession of Damascus, and died there in the year 635 (A.D. 1238). He was distinguished by military talents and rare moderation, and was also a learned man, a patron of the arts, and a good king.

His son, El-Melik El-Adil the Younger, was declared sultan of Egypt in the reign of Elyoob, and he carried on his wars against the Franks, and purposed the conquest of Egypt, the hostile armies met at Acre, and the Musulman soldiers of Elyoob desiring to form a bar of resistance on the sea, the Franks were routed. Negotiations for peace were then attempted, but these failing, the Franks were again induced to take the field by the cession of Jerusalem and other places. The king of Egypt, on his part, declared, in justice to the Sultan, when he had assuaged his implacable enmity, Damascus, which took Jerusalem and overran Syria. In the next campaign (642) they were joined by the army of Elyoob, under the command of Sheger-ed-Durr, who was destined to play a conspicuous part in Egyptian history. At Gaza the allied army met the Franks, eager to avenge themselves on the Khareem Khareem, who had been guilty in the preceding campaign, and willingly joined by the Muslim princes of Damascus, Homs, and Hama, on the first day they carried with decisive victory from daybreak to sunset, and was continued on the morrow until the prince of Homs, having lost 2000 men, gave way and fled towards Damascus. The Christians manifestly under the unequal fight with great constancy, and were only vanquished after the greater number had fallen. In these encounters, 20,000 men (and perhaps 30,000), two-thirds of the nobles, and heroically harnessed those munitions whose counsel he feared, and appointed creatures of his own. Oppressed by his tyranny, and impoverished by his wasting expenditure on fabulous conditions, his son Alee, ed-Deen Eybek to the throne, and he deposed and imprisoned El-Adil in the year 637, and to replenish his exhausted treasury, engaged to pay 400,000 livres as a ransom for himself and his army, 200,000 to be paid in Egypt, and the remainder on the fulfillment of certain stipulations at Acre. Damascus was surrendered in a few days, and the invasion of the Crusaders Sheger-ed-Durr, in order to strengthen herself on the throne, shortly after married the enemy Eybek, and caused him to be sent into the service of El-Melik El-Mansoor Noor-ed-Deen, when the battle of the year 648. The followers of the late Elyoob, however, obdurate Eybek to associate with himself in the sovereignty a young prince the grandson of Eybek, El-Meher, and the Tatars of Egypt evacuated. Sheger-ed-Durr, a son of El-Areeb, invaded Egypt, and after many combats was driven back to Syria, but he continued to exist, and kept several deserts of Egypt, and the next day landed opposite force and marched to meet him. Very severe the struggle, and the body of the enemy a ford over the canal of Thoron and Damascus, and, not trusting to the Memlouks, Damascus was set on fire. The forces of El-Melik El-Mansoor Noor-ed-Deen advanced towards Damascus, and his body-guard, who composed his army, the wretched emperor had, however, in the meantime recalled Hoolagoo, who left Kethba to encounter the Egyptian sultan. The battle declared in favour of the latter, and Syria was restored to his rule. Returning in triumph to Egypt, he was assassinated on the frontier by Beybars in the year 658, and this Memlouk (who had just recently bought under his banner against the Fatara) was forthwith chosen by the emirs to be his successor.

The brilliant reign of El-Melik Ed-dahar Beybars El-Baungdokhri is so peripatetic and fall of incident as to render a complete account of it very difficult. It began with the reduction of a revolt in Syria. The rebels were supported by Saladin under Hoolagoo, but Beybars was everywhere victorious, and Damascus surrendered at discretion. Having subdued all opposition in this quarter, he endeavoured to improve the conquests, the able El-Melik proclaimed himself sultan El-Melik El-Meher, Katt was begun by putting to death El-Mansoor and Sharaf-ed-Deen El-Mansoor and the kings of the latter dynasty. A reign thus cruelly commenced ended tragically. Katt was diverted from these severe measures by the advance of the Crusaders, and he sent to propose a truce, but not coming to terms he resolved on retreating to Damascus. A memorable conquest took place by land and sea, and St Louis with his troops surrendered themselves prisoners of war. Toen-Siah now gave himself up to debauchery, offended his nobles by bestowing his favours only on certain creatures whom he had brought with him from Mesopotamia, and alarmed the queen by bringing her to render him an account of his father's wealth. Sheger-ed-Durr appealed to the Memlouks, a conspiracy was formed, and the sultan was attacked in his palace. He fled to a pleasure-ground built on the banks of the Nile, which was set on fire in the presence of his army, the wretched king, from the summit, in vain promising to abdicate. He perished miserably, and his corpse lay unburied for many days on the bank. On his accession he had arranged a brother, and his fate deserves no pity.

Sheger-ed-Durr (vagarily called Shegeriy-ed-Durr), herself a slave, and the first of the Dynasty of the Bahrein,姬 tourists Memlouks, succeeded to the throne, and Izz-ed-Denn Eybek was appointed commander of the forces. After many delays, it was agreed to pay 400,000 livres as a ransom for himself and his army, 200,000 to be paid in Egypt, and the remainder on the fulfillment of certain stipulations at Acre. Damascus was surrendered in a few days, and the invasion of the Crusaders Sheger-ed-Durr, in order to strengthen herself on the throne, shortly after married the enemy Eybek, and caused him to be sent into the service of El-Melik El-Mansoor Noor-ed-Deen, when the battle of the year 648. Toen-Siah now gave himself up to debauchery, offended his nobles by bestowing his favours only on certain creatures whom he had brought with him from Mesopotamia, and alarmed the queen by bringing her to render him an account of his father's wealth. Sheger-ed-Durr appealed to the Memlouks, a conspiracy was formed, and the sultan was attacked in his palace. He fled to a pleasure-ground built on the banks of the Nile, which was set on fire in the presence of his army, the wretched king, from the summit, in vain promising to abdicate. He perished miserably, and his corpse lay unburied for many days on the bank. On his accession he had arranged a brother, and his fate deserves no pity.

Sheger-ed-Durr (vagarily called Shegeriy-ed-Durr), herself a slave, and the first of the Dynasty of the Bahrein,姬 tourists Memlouks, succeeded to the throne, and Izz-ed-Denn Eybek was appointed commander of the forces. After many delays, it was agreed to pay 400,000 livres as a ransom for himself and his army, 200,000 to be paid in Egypt, and the remainder on the fulfillment of certain stipulations at Acre. Damascus was surrendered in a few days, and the invasion of the Crusaders Sheger-ed-Durr, in order to strengthen herself on the throne, shortly after married the enemy Eybek, and caused him to be sent into the service of El-Melik El-Mansoor Noor-ed-Deen, when the battle of the year 648. The followers of the late Elyoob, however, obdurate Eybek to associate with himself in the sovereignty a young prince the grandson of Eybek, El-Meher, and the Tatars of Egypt evacuated. Sheger-ed-Durr, a son of El-Areeb, invaded Egypt, and after many combats was driven back to Syria, but he continued to exist, and kept several deserts of Egypt, and the next day landed opposite force and marched to meet him. Very severe the struggle, and the body of the enemy a ford over the canal of Thoron and Damascus, and, not trusting to the Memlouks, Damascus was set on fire. The forces of El-Melik El-Mansoor Noor-ed-Deen advanced towards Damascus, and his body-guard, who composed his army, the wretched emperor had, however, in the meantime recalled Hoolagoo, who left Kethba to encounter the Egyptian sultan. The battle declared in favour of the latter, and Syria was restored to his rule. Returning in triumph to Egypt, he was assassinated on the frontier by Beybars in the year 658, and this Memlouk (who had just recently bought under his banner against the Fatara) was forthwith chosen by the emirs to be his successor.
and its territory was added to his dominions. A great scarcity of provisions and a threat of invasion affected Cairo in 662, and Baybars threw upon the Government the onus, and swore in every way to avert the sufferings of his subjects.

In 663 he again entered Syria, and took Caesarea and Umurof; and in the next year he commenced a series of campaigns against the Christians, notwithstanding the existence of a truce. He says the expenses of the war, he took occasion from the occurrence of many sedition fires in Cairo, during his absence, to annull their telegrams. A body of 500,000 demics,共计ing with the aid of his army, Baybars despatched a force which effected the conquest of Jerusalem, and then to the borders of Anatolia, a transient success which was speedily annulled by the advent of Alah Khan, the son of Hoolago.

The next war, Baybars again attacked the Christians, burning their churches and evicting the population, forcing Hissam and Hamsh, and thence returned to Cairo. After a campaign against the Tatars, he ravaged the country around Cairo (the burning of the villages, destroying human beings, and the like), and supported the optics of his actions, one commanded by himself in person, the other by Kala-oon El-Eldin. In the battle of Beyrah the sultan was captured, and this time he was not to escape the damage caused by these fires. He threatened and calmed, and relieved from the apprehensions caused by the advent of the Tatars by the death of Hoolago and the interest of his army, Baybars despatched a force which effected the conquest of Jerusalem, and then to the borders of Anatolia, a transient success which was speedily annulled by the advent of Alah Khan, the son of Hoolago.

MEMLOOK SULTANS

EGYPT

now undisputed master of Egypt. He was the first prince of the Dynasty of Burgee or Cireman Memlooks. As the preceding dynasty was founded by the Turkish preachers of El-Sallih Egypt, so this dynasty was composed of the Cireman slaves whom those kings from time to time bought with the view of strengthening their power. They were originally placed in the character of a garison, or garrison of the place, hence their name Burgee, signifying 'of a tower or castle' It is worthy of remark that, while many of the sultans of both these dynasties were foremost ten men against the Turks, many of the latter met with a violent death, but few of the latter. The reign of Barkook is memorable for his war with Teemoor, or Teemoor-ling, commonly called by us Tangerian, who had extended his conquests towards his dominions, but found him not unprepared, for he had foreseen the threatened danger. In the year 795, Kars-Yossuf, Lord of El-Melesche, and Ahmad Isla'meh, a similar personage to Barkook, were descended to the sword, and Aleppo was the scene of the battle, when the Turks were repulsed, and returned with the spoils they had committed, and possession the military talents of Farag were not sufficient to offset his severity. He seems to have been fond of riches and display, and he certainly left his treasury in a very flourishing condition, besides much wealth in stores, slaves, horses, and the like.

His son, El-Melahk En-Na'sr Abu-S-Salih Farag, fell a prey to unexpected sickness and the usual weakness of, but he outlived the sultan, his kingdom. He died suddenly in 801, much beloved by his subjects and regarded by less powerful chiefs as their strongest bulwark against the Fatir monarch. He was called 'Shaykh,' for his wisdom and learning, and combated with those qualities those of a skilful general and a good king. He was active, wary, and the most capable of his age, and possessed the various qualities that distinguished him out the seventy. He seems to have been fond of riches and display, and he certainly left his treasury in a very flourishing condition, besides much wealth in stores, slaves, horses, and the like. The next sultan, El-Melahk En-Na'sr Abu-S-Salih Farag, was proclaimed king by Barkook's adherents, and concluded a treaty with the sultan of Egypt.

His design against Indus diverted Teemoor from his projects in Syria, but Barkook continued his venture and every means he could devise to insurrection the sultan's dominions. He was sulla's behind him, and Ahmad Isla'meh, a similar personage to Barkook, were descended to the sword, and Aleppo was the scene of the battle, when the Turks were repulsed, and returned with the spoils they had committed, and possession the military talents of Farag were not sufficient to offset his severity. Egypt

This event took place on the 29th of Regeb 922 (A.H. 1516) with the treaty of Belqas, by which the Egyptians lost their independence. The shattered remains of the army collected in Cairo. Tolunay Bey, a nephew of the deceased king, was elected sultan, and at once determined on every resource to the conqueror. His general in Syria, El-Gambardes, disputed the road with Selim step by step, and at last after arreling near Cairo, commanded the retreating Turks, and the brilliant bravery of the Memlooks availed them not, immense numbers of them were slain by their enemies in the pursuit, and the survivors, El-Gambardes, however, secured his name by joining the victor. The Turkish army paused for rest; and time was thus given to Tolunay Bey to hire Arabs at a great cost to replenish his thinned ranks. Selim now passed to the west of Cairo. A night surprise conducted by Tolunay failed, but he succeeded in putting to the sword a great many Turks. He fortified himself in the city, and a house-to-house combat ensued, the Memlooks defending every foot with the energy of despair; the battle fell by assault, and the unfortunate Tolunay expired in the arms of his Egyptians; but on the way he was taken by Arabs, given up to El-Gambardes and another, and brought in chains to Selim, who at first received him with honour, but afterwards falsely accused him of conspiring against him, and, with the cruelty and perfidy characteristic of his race, hung him over the Bab-Zawyleh, the place of execution for common felons. Thus miserably perished the last independent ruler of Egypt, who possessed the best qualities of his line, and whose noble defence of his kingdom would have secured to him the commendation of any but a Turk.

In reviewing the period during which Egypt was governed by independent Muslim princes, it is necessary to consider the spirit of the times and the people over whom they ruled. They succeeded to the government of countries worn out by incessant warfare, overrun by savage hordes, and debased by the rule of the Lower Empire. Egypt had long struggled against the slavery to which it was condemned, and the history of the last three dynasties of Pharaohs vivified Cairo. But the house of Eiyyub it attained its greatest military glory under the Benee-Tooroos and the Ikhsheedeeyeh) from profiting by the enlightenment of the race who held the dominion over it, until the conquest by the Fatimees. The caliphs of that dynasty contributed in a great degree to restore to Egypt its ancient portion of its ancient glory, and with the house of Eiyyub it attained its greatest military glory under the Muslims; but the edifices erected during the rule of the two dynasties of Memlook kings, the libraries collected in Cairo at that period, and the learned men who then flourished would point to it as the age in which literature and arts were cultivated with the most success, a sure evidence of the internal prosperity of any country. This is the more surprising when we consider the state of Syria, which had long before its accession fallen a prey to intestine wars and the ravages of the Tartars, the Crusaders, and other invaders, and also bear in mind the constitution of their government, in which the more powerful chiefs were constantly aiming at the supreme authority; and the practice of purchasing memlooks, and rearing them in the households of the great to enable their masters to maintain their ascendancy augmented the number of these aspirants to the throne. These slaves were, unlike the Bahaeeeyeh, the Turkish Memlooks of Es-Saith Eiyyub, chiefly Circassians, who afterwards composed the Second (or Burge) Dynasty. Many of the Memlook sultans railed in military achievements the great Saladin, and even penetrated further than he in their foreign expeditions. In Cairo the still seen the finest specimens of Arab architecture, almost all dating during the period comprised under the domination of the two Memlook dynasties; the libraries of the mosques, and the private collections of this city, though grievously injured since the Turkish conquest, are or very recently were the best and most considerable of those of Egypt or Syria; and, as before remarked, the university El-Azhar is still, owing to the fostering care of these sultans, the principal seat of learning of the Eastern world.

In this sketch of the history of Egypt we have given no account of the state of commerce, taxation, &c., under the Muslims. Those only who have read the Arab histories of this and other Eastern countries can appreciate the general futility of the conclusions based on their authority.

It would be tedious and unprofitable to follow the details of Turkish misrule and tyranny which are from this time presented to the student of Egyptian history. Although Selim had apparently destroyed the power of the Memlooks, he thought it prudent to conciliate them, and appoint twenty-four beys over the military provinces of that number into which he divided Egypt, subject to the supreme control of a pasha, whose council was formed of seven Turkish chiefs (oaklees), while one of the beys held the post of Sheykh El-Beled, or Governor of the Metropolis, an officer who became an object of hatred to the other chiefs. This system was begun by Selim, and completed by his successor. For nearly two centuries the successive pashas were mostly obeyed; but the ambition of becoming Sheykh El-Beled was the fruitful cause of intrigue and murder. The Memlooks who then held power in Egypt were called the Ghuzz, that being the name of the tribe to which they are said to have at first generally belonged; and they continually bought slaves, of Circassian or Georgian race, to supply the place of children, for they did not intermarry with natives of Egypt, and women of more northern climates are generally either barren or bear sickly offspring in that country. Thus they lacked the surest source of power; few possessed any family ties; but at the same time the slaves in general were remarkably faithful to their patrons. After two centuries, the beys gradually increased in power, until the authority of the pasha was almost nominal, and the government became a military oligarchy. This brings us to the rise of the celebrated Ali Bey. He was created Sheykh El-Beled in A.H. 1177; but, having revenged himself on an old enemy who had assassinated Ali's master, to whom he owed his elevation to the rank of bey, he shortly after fled to Syria, and took refuge with the governor of Jerusalem, and thence went to Acre, where the Sheykh Dhahir became his friend; and that same year he returned to Cairo in his former capacity of Sheykh El-Beled. In 1179 his enemies again compelled him to flee, and he betook himself this time to El-Yemen, once more to return to Egypt; after which he gained increased power. His favourite memlook, Muhammad Aboob-Dahabab, proved ungrateful, and, while enjoying the highest power, entered into a conspiracy against his life; but after receiving the presents of the hostile beys, he denounced them to his master, who would not listen to warnings of his meditated treachery.

In the year 1182 (A.D. 1768) the Porte demanded the assistance of Ali Bey in the Russian war, an order which he was about to obey, when he was apprised of the departure of a messenger with a firman demanding his head, he having been falsely accused of intentions to aid the Russians and throw off his allegiance. He caused the bearer of this order to be waylaid and put to death, and having possessed himself of the firman, he continued...
vened the beys, showed them the document, and aided by those of his own household persuaded the council to expel the pasha, and declare Egypt independent. The Sheykh Dhaahir took part in this rebellion, and the pasha of Damascus was beaten by him between Mount Lebanon and Tiberias. A period of good but vigorous government and of tranquillity followed these events in Egypt, notwithstanding the very heavy imposts levied for the replenishment of the treasury; and Ali's generals gained for him extended power abroad. Mohammad Abou-Dhahab was despatched to Arabia, and entered Mecca, where the Shereef was deposed; and another bey traversed the eastern shores of the Red Sea. After the expedition to Arabia, Mohammad Bey marched into Syria to assist the Sheykh Dhaahir against the Porte, and the co-operation of the Russans was demanded. A successful campaign terminated before the walls of Damascus, the siege of which was abandoned when nearly brought to a close, and Mohammad Bey returned with large forces to Egypt. This man, loaded with benefits by his patron, now openly rebelled; and being joined by Ali's enemies, at the head of 5000 men was Ismail, chief of the guard, he advanced on Cairo, and Ali escaped to his steady ally, Sheykh Dhaahir, the prince of Acre. These events took place the year 1186. Mohammad Bey was then declared Sheykh el-Beled. Ali Bey, in the meanwhile, in conjunction with his ally, gained various advantages in Syria, and, on the information that his return was desired in Egypt, he collected a small force, assisted by Sheykh Dhaahir and a Russian squadron, and determined on attempting to recover his power. He, however, fell into an ambuscade near Es-Sakkaryeh, and was wounded by one of his moollahs named Murad (afterwards Murad Bey), carried to the citadel, and poisoned by Mohammad Bey. Thus terminated the career of the famous Ali Bey, a man whose energy, talents, and ambition bear a strong resemblance to those of the latter Mehemet Ali. Mohammad Bey continued Sheykh el-Beled, tendered his allegiance to the Porte, and was invested with the pashalik. He then entered Syria, and severely chastised Sheykh Dhaahir, taking Gaza, Joppa, and Acre itself. Joppa was taken by assault, and suffered a massacre of its inhabitants, and Acre was pillaged. At the latter place the pasha suddenly died. His mosque in Cairo is the latest fine specimen of Arab architecture, and is not unworthy of its better days.

The chief competitors for power were now Ismail, Ibrahim, and Murad. The first of whom was speedily expired in the contest continued between the two latter beys. Ibrahim at length succeeded in casuing himself to be proclaimed Sheykh el-Beled, and Murad contended himself with the office of Emoor el-Hagg, or chief of the pilgrims; but this arrangement was not destined to be of long continuance; a violent quarrel resulted in a recourse to arms, and that again in a peace of three years' duration, during which the two beys held an equal sway. In the year 1200 the Porte despatched Hassan Capitan (properly Kapoodan) Pasha (or High Admiral), with a Turkhah force, to reduce the turbulent Moollahs to obedience, and to claim the annual tribute. Murad Bey was overtaken at El-Beled, and the Turks advanced to Cairo, desolating the country, and acting according to their almost invariable practice on such occasions. The metropolis opened its gates to Hasam Pasha, who determined on pursuing the beys to Upper Egypt, whether he despatched a large portion of his army, and a sailing squadron, or took place, but a war with Russia recalled this commander to Constantinople. Ismail was again created Sheykh el-Beled, and he held that post until the terrible plague of the year 1205, in which he perished, and hence it is commonly called the "Plague of Ismail." His death caused the return of Ibrahim and Murad; and

eight years after, intelligence of the arrival at Alexandria of a French army of 36,000 men, commanded by General Bonaparte, united these chiefs in a common cause.

On the 18th May 1798, this expedition, consisting of 13 sail of the line, 6 frigates, and 12 vessels of a smaller size, sailed from Toulon, and made the coast of Egypt on the 1st July. The troops were landed near Alexandria, and the city fell by assault on the 5th of that month. The French conquest and occupation of Egypt belong to European history; a recapitulation of the principal events of the period will therefore suffice in this place. The Memlooks affected to despise their antagonist, and hastened to chastise him; at Shibrrees they attacked the French and were repulsed; but, nothing discouraged, they collected all their forces, exceeding 60,000 men, under the command of Murad, and entrenched themselves at Embabeh, opposite Cairo. Here was fought the battle which has been dignified with the name of that of the Pyramids. European tactics completely bewildered the Memlooks: their famous cavalry was received on the bayonets of the French squares; a galling fire of grape and musketry mowed down their ranks; and of this great army only about 2500 horses escaped with Murad Bey, while 15,000 men of all arms fell on the field of battle. Having made himself master of Cairo, Bonaparte despatched General Desaix to effect the conquest of Upper Egypt, and the success of the Eastern expedition seemed secured. But ten days after the victory of Embabeh, the battle of the Nile annihilated the French fleet in Abooe-Keer (Aboukir) Bay, and most materially influenced the future conduct of the war. On this point, Napoleon himself says, "La perte de la bataille d'Aboukir eut une grande influence sur les affaires d'Egypte et même sur celles du monde; la flotte française ayant, l'expédition de Syrie n'opposant point d'obstacles, l'artillerie de siège se transportait sûrement et facilement au-delà du désert, et Saint-Jean-d'Acre n'arrêterait point l'armée Françoise. La flotte Française détruite, le divan s'enthousiasme à déclarer la guerre à la France. L'armée perdit un grand appui, sa position en Egypte changea totalement, et Napoleon dut renoncer à l'espoir d'assouvir à jamais la puissance Française dans l'Orient par les résultats de l'expédition d'Egypte."

The disastrous expedition into Syria, undertaken for the purpose of frustrating the efforts of Sir Sydney Smith before Alexandria, and of Jozzár Pasha, who was advancing from Acre, still further obscured Napoleon's prospects in the East, and the victory soon after obtained by him over the Ottoman army at Abooe-Keer, the second defeat of Murad Bey, and various successes over the Turks, enabled the French general Kleber (Napoleon having left for Europe after the first of these events) to set on foot negotiations for an honourable evacuation of the country. But when the convention was already signed, and the French were about to quit Cairo, Lord Keith signified to Kleber that Great Britain would not consent to the terms of the treaty; and although this refusal was afterwards rescinded, Kleber considered that the withdrawal came too late: he totally defeated 70,000 men under the grand vizir at Heliopolis, and returned to Cairo to quell an insurrection of the inhabitants. This distinguished officer was about this time assassinated in the garden of his palace by a fanatic, who was impaled in the great square (then a lake) called the Esbakeeyeh, in Cairo, and mournfully lingered for the space of three days before death put an end to his sufferings. Under Kleber's administration, Egypt began to resume its former prosperity; by his conciliatory and good government much prejudices against the French was overcome; by ceding a part of Upper Egypt to Murad, he gained the good will of that chief, who gave him no cause to regret.  

1 Napoleon, Mémoires, t. ii.
this politic step; while under his auspices the "savans" of the Institute of Egypt collected the valuable mass of information embodied in the "great French work," the Description de l'Egypte.

On the death of Kleber, General Menou succeeded to the command, and although he afterwards conducted the defence of the country with much valour, yet to his judgment in administration and his want of military talent, we must mainly ascribe the determination of the British Government to attempt the expulsion of the French from Egypt, and the rapid success of the campaign that ensued. On the 2d of March 1801 an army under Sir Ralph Abercromby arrived in Aboo-Keer Bay, and made good a landing in the face of a well-disposed French force, which offered every possible resistance. The memorable battle of Alexandria, in which Abercromby fell, decided the fate of the war. A bold march, executed with talent, effected the capitulation of Cairo; Alexandria surrendered on the 1st of September, and the French sailed from the shores of Egypt in the course of that month. General Hutchinson had taken the command of the English expedition, afterwards reinforced by a detachment from India under General Baird; and the army of the grand vizir, and that of the capitam-pasha, with the troops of Ibrahim Bey (for Khusruf, having died of the plague), had co-operated in the measures which led to the evacuation of the country by Menou.

The history now requires that we should mention the early career of a man who subsequently ruled the destinies of Egypt for a period of nearly forty years. Mehemet Ali Pasha was born in A.H. 1182 (A.D. 1768-9) at Cavalla, a small sea-port town of Albania. On the death of his father, in early life, he was brought up in the house of the governor of the town, who, as a reward for military prowess, gave him his daughter in marriage. By her he had, it is said, his three eldest sons, Ibrahim, Tocsoon, and Ismail. Having attained the rank of bahlit-bashhe (or head of a body of infantry), he became a dealer in tobacco, until, in his thirty-third year, he was despatched to Egypt with his patron's son, Ali Agha, and 300 men, the contingent furnished by his native place to the Turkish government, under the French, and soon after his arrival in that country he succeeded, on the return of Ali Agha, to the command, with the nominal rank of beeibashshe (or chief of a thousand men).

Soon after the evacuation of Egypt by the French, that unfortunate country became the scene of more severe troubles, in consequence of the unwarrantable attempts of the Turks to destroy the power of the Ghuzz. In defiance of promises to the English Government, orders were transmitted from Constantinople to Hoseyn Pasha, the Turkish high admiral, to ensnare and put to death the principal boys. Invited to an entertainment, they were, according to the Egyptian contemporary historian El-Gebarte, attacked on board the flagship; Sir Robert Wilson and M. Mengin, however, state that they were fired on, in open boats, in the bay of Aboo-Keer. They offered an heroic resistance, but were overpowered, and some made prisoners, some killed, while some, including the afterwards celebrated Osman Bey El-Bardeese, escaped in a boat, and sought refuge with the English, who at that time occupied Alexandria. General Hutchinson, informed of this treachery, immediately assumed threatening measures against the Turks, and in consequence, the killed, wounded, and prisoners were given up to him. Such was the commencement of the distressing struggle between the Memlooks and the Turks. Mohammad Khursuf was the first pasha after the expulsion of the French. The form of government, however, was not the same as that before the French invasion, for the Ghuzz were not reinstated. The pasha, and through him the sultan, endeavoured on several occasions either to ensnare them or to beguile them into submission; but these efforts failing, Mohammad Khursuf took the field, and a Turkish detachment 14,000 strong, despatched against them to Demeenoor, whither they had descended from Upper Egypt, was defeated by a small force under El-Effee; or, as Mengin says, by 800 men left by El-Effee under the command of El-Bardeese. Their ammunition and guns fell into the hands of the Memlooks.

In March 1803 the British evacuated Alexandria, and Mohammad Bey El-Effee accompanied them to England to consult respecting the means to be adopted, or restoring the former power of the Ghuzz. About six weeks after, the Arnaoot (or Albanian) soldiers in the service of Khursuf tumultuously demanded their pay, and surrounded the house of the defterdar, who in vain appealed to the pasha to satisfy their claims. The latter opened fire from the artillery of his palace on the insurgent soldiery in the house of the defterdar, across the Esbekeyeh. The citizens of Cairo, accustomed to such occurrences, immediately closed their shops, and the doors of the several quarters, and every man who possessed any weapon armed himself. The tumult continued all the day, and the next morning a body of troops sent out by the pasha failed to quell it. Tahir, the commander of the Albanians, then repaired to the citadel, gained admittance through an embrasure, and, having obtained possession of it, began to cannonade the pasha over the roofs of the intervening houses, and then descended with guns to the Esbekeyeh, and laid close siege to the palace. On the following day, Mohammad Khursuf made good his escape, with his women and servants and his regular troops, and fled to Damietta by the river. This revolt marks the commencement of the rise of Mehemet Ali to power in Egypt, and of the breach between the Arnaoots and Turks which ultimately led to the expulsion of the latter.

Tahir Pasha assumed the government, but in twenty-three days he met with his death from exactly the same cause as that of the overthrow of his predecessor. He refused the pay of certain of the Turkish troops, and was immediately assassinated. A desperate conflict ensued between the Albanians and Turks; and the palace was set on fire and plundered. The masters of Egypt were now split into these two factions, animated with the fiercest animosity against each other. Mehemet Ali became the head of the former, but his party was the weaker, and he therefore entered into an alliance with Ibrahim Bey, and Osman Bey El-Bardeese. A certain Ahmed Pasha, who was about to proceed to a province in Arabia, on which he had been appointed governor, was raised to the important post of pasha of Egypt, through the influence of the Turks and the favour of the shekhs; but Mehemet Ali, who with his Albanians held the citadel, refused to assent to their choice; the Memlooks moved over from El-Geezeh, and Ahmad Pasha betook himself to the monastery of Ez-Zahir, which the French had converted into a fortress. He was compelled to surrender by the Albanians; the two chiefs of the Turks who killed Tahir Pasha were taken with him and put to death, and he himself was detained a prisoner. In consequence of the alliance between Mehemet Ali and El-Bardeese, the Albanians gave the conqueror to the Memlooks; and soon after, these allies marched against Khursuf Pasha, who having been joined by a con-

1 Very many of the French had either married Memlook women, or bought concubine slaves of the same faith, whom, on their departure, they left behind them; and these unfortunate were forthwith tied up in necks and downed.
2 Ibrahim is, however, believed by many, or most, to have been the wife's son by a former husband.
siderable body of Turks, and being in possession of Damietta, was enabled to offer an obstinate resistance. After much loss on both sides, he was taken prisoner and brought to Cairo; but he was treated with respect. The victorious soldiery sacked the town of Damietta, and were guilty of the barbarities usual with them on such occasions.

A few days later, Ali Pasha El-Tarabulusee landed at Alexandria with an imperial frigate, constituting him pasha of Egypt, and threatened the Beys, who now were virtual masters of Upper Egypt, as well as of the capital and nearly the whole of Lower Egypt. Mehemet Ali and El-Bardeesee therefore descended to Rosetta, which had fallen into the hands of a brother of Ali Pasha, and having recovered the town and captured its commander, El-Bardeesee purposed to proceed against Alexandria; but the troops required arrears of pay which it was not in his power to give, and the pasha had cut the dyke between the Lakes of Aboo-Keer and Mareehs, thus rendering the approach to Alexandria more difficult. El-Bardeesee and the Mehemet Ali therefore returned to Cairo. The troubles of Egypt were now increased by an insufficient inundation, and great scarcity prevailed, aggravated by the exorbitant taxation to which the Beys were compelled to resort in order to raise money to pay the troops; while murder and rapine prevailed to a frightful extent in the capital, the riotous soldiery being under little or no control. In the meantime, Ali Pasha, who had been behaving in an outrageous manner towards the Franks in Alexandria, received a khatt-i-shereef from the sultan, with an annual pension each of fifteen purses and other privileges, but that the government should be in the hands of the pasha. To this the Beys assented, but with considerable myrmogryves; for they had intercepted letters from Ali to the Albanians, endeavouring to alienate them from their suzerain, and thus securing the assistance of the Beys. Desperate answers were returned to these, and Ali was induced by them to advance towards Cairo at the head of 2500 men. The forces of the Beys, with the Albanians, encamped near him at Shalaklem, and he fell back on a place called Zafyeteel. They next seized his boats conveying soldiers, servants, and his ammunition and baggage; and, following him, they demanded whither he brought with him so numerous a body of men, in opposition to usage and to their previous warning. Finding they would not allow his troops to advance, forbidden himself to retreat with them to Alexandria, and being surrounded by the enemy, he would have hazarded a battle, but his men refused to fight. He therefore repaired to the camp of the Beys, and his army was compelled to retire to Syria. In the hands of the Beys, Ali Pasha again attempted treachery. A horseman was seen to hand him an order one night at full gallop; he was the bearer of a letter to Osmany Bey Hassan, the governor of Kne. This offered a fair pretext to the Memlooks to rid themselves of a man whose antecedents and present conduct proved him to be a perfidious tyrant. He was sent under a guard of forty-five men towards the Syrian frontier; and about a week after this news was received that in a skirmish with some of his own soldiers he had fallen mortally wounded.

The death of Ali Pasha produced only temporary tranquillity; in a few days the return of Mohammed Bey El-Effie (called the Great or Eldee) from England was the signal for fresh disturbances, which, by splitting the Ghuzz into two parties, accelerated their final overthrow. An ancient jealousy existed between El-Effie and the other most powerful bey, El-Bardeesee. The latter was now supreme among the Ghuzz, and this fact considerably heightened their enmity. While the guns of the citadel, those at Mass El-Ateekah, and even those of the palace of El-Bardeesee, were three fired in honour of El-Effie, preparations were immediately commenced to oppose him. His partisans were collected opposite Cairo, and El-Effie was driven away; but he still held El-Geezeh among them; Hoseyn Bey El-Effie was assassinated by emissaries of El-Bardeesee, and Mehemet Ali, with his Albanians, gained possession of El-Geezeh, which was, as usual, given over to the troops to pillage. In the meanwhile El-Effie made a great embarkation at Rosetta, and not apprehending opposition, was on his way to Cairo, when a little south of the town of Manoof he encountered a party of Albanians, and with difficulty made his escape. He gained the eastern branch of the Nile, but the river had become dangerous, and he fled to the desert. There he had several hard-breadth escapes, and at last secreted himself among a tribe of Arabs at Ras-el-Wads. A change in the fortune of El-Bardeesee, however, favoured his plans for the future. That chief, in order to satisfy the demands of the Albanians for their pay, gave orders to levy heavy contributions from the citizens of Cairo; and this new oppression aroused them to rebellion. The Albanians, alarmed for their safety, assured the populace that they would not allow the order to be executed; and Mehemet Ali himself caused a proclamation to be made to that effect. Thus the Albanians became the favourites of the Beys and took advantage of their opportunity. Three days later they beset the house of the aged Ibrahim Bey, and that of El-Bardeesee, both of whom effected their escape with difficulty. The Memlooks in the citadel directed a fire of shot and shell on the houses of the Albanians which were situated on the Ezbekkeyeb; but on hearing of the flight of their chiefs, they evacuated the place; and Mehemet Ali, on gaining possession of it, once more proclaimed Mahomet Khursuf pasha of Egypt. For one day and a half he enjoyed the title; the friends of the late Tahir Pasha then accomplished his second degradation, and Cairo was again the scene of terrible enormities, the Albanians ravelling in the houses of the Memlooks chiefs, whose hareems met with no mercy at their hands. These events were the signal for the reappearance of El-Effie.

The Albans now invited Ahmad Pasha Khursheed to assume the reins of government, and he without delay proceeded from Alexandria to Cairo. The forces of the partisans of El-Bardeesee were ravaging the country a few miles south of the capital and intercepting the supplies of corn by the river, a little later they passed to the north of Cairo and succeeded by the encirclement he would have hazarded a battle, but his men refused to fight. He therefore repaired to the camp of the Beys, and his army was compelled to retire to Syria. In the hands of the Beys, Ali Pasha again attempted treachery. A horseman was seen to hand him an order one night at full gallop; he was the bearer of a letter to Osmany Bey Hassan, the governor of Kne. This offered a fair pretext to the Memlooks to rid themselves of a man whose antecedents and present conduct proved him to be a perfidious tyrant. He was sent under a guard of forty-five men towards the Syrian frontier; and about a week after this news was received that in a skirmish with some of his own soldiers he had fallen mortally wounded.

The death of Ali Pasha produced only temporary tranquillity; in a few days the return of Mohammed Bey El-Effie (called the Great or Eldee) from England was the signal for fresh disturbances, which, by splitting the Ghuzz into two parties, accelerated their final overthrow. An ancient jealousy existed between El-Effie and the other most powerful bey, El-Bardeesee. The latter was now supreme among the Ghuzz, and this fact considerably heightened their enmity. While the guns of the citadel, those at Mass El-Ateekah, and even those of the palace of El-Bardeesee, were three fired in honour of El-Effie, preparations were immediately commenced to oppose him. His partisans were collected opposite Cairo, and El-Effie was driven away; but he still held El-Geezeh among them; Hoseyn Bey El-Effie was assassinated by emissaries of El-Bardeesee, and Mehemet Ali, with his Albanians, gained possession of El-Geezeh, which was, as usual, given over to the troops to pillage. In the meanwhile El-Effie made a great embarkation at Rosetta, and not apprehending opposition, was on his way to Cairo, when a little south of the town of Manoof he encountered a party of Albanians, and with difficulty made his escape. He gained the eastern branch of the Nile, but the river had become dangerous, and he fled to the desert. There he had several hard-breadth escapes, and at last secreted himself among a tribe of Arabs at Ras-el-Wads. A change in the fortune of El-Bardeesee, however, favoured his plans for the future. That chief, in order to satisfy the demands of the Albanians for their pay, gave orders to levy heavy contributions from the citizens of Cairo; and this new oppression aroused them to rebellion. The Albanians, alarmed for their safety, assured the populace that they would not allow the order to be executed; and Mehemet Ali himself caused a proclamation to be made to that effect. Thus the Albanians became the favourites of the Beys and took advantage of their opportunity. Three days later they beset the house of the aged Ibrahim Bey, and that of El-Bardeesee, both of whom effected their escape with difficulty. The Memlooks in the citadel directed a fire of shot and shell on the houses of the Albanians which were situated on the Ezbekkeyeb; but on hearing of the flight of their chiefs, they evacuated the place; and Mehemet Ali, on gaining possession of it, once more proclaimed Mahomet Khursuf pasha of Egypt. For one day and a half he enjoyed the title; the friends of the late Tahir Pasha then accomplished his second degradation, and Cairo was again the scene of terrible enormities, the Albanians ravelling in the houses of the Memlooks chiefs, whose hareems met with no mercy at their hands. These events were the signal for the reappearance of El-Effie.

The Albans now invited Ahmad Pasha Khursheed to assume the reins of government, and he without delay proceeded from Alexandria to Cairo. The forces of the partisans of El-Bardeesee were ravaging the country a few miles south of the capital and intercepting the supplies of corn by the river, a little later they passed to the north of Cairo and succeeded by the encirclement
on both sides. This reverse in a measure united the two
great Mameluk parties, though their chiefs remained at
enmity. El-Bakoury, however, passed to the south of Cairo, and
the Ghuzza gradually retreated towards Upper Egypt.

Neither the pasha despatched three successive expeditons
(one of which was commanded by Mehemet Ali); and many
battles were fought, but without decisive result.

At this period another army befell Egypt; about 3000
Deless arrived in Cairo from Syria. These troops had been
sent for by Khurshedd in order to strengthen himself
against the Albanians; and the events of this portion of
the history afford sad proof of their ferocity and brutal
enmities, in which they far exceeded the ordinary Turkish
soldiers and even the Albanians. Their arrival immediately
recalled Mehemet Ali and his party from the war, and in-
stead of aiding Khurshedd was the proximate cause of his
overthrow.

Cairo was ripe for revolt; the pasha was hated for his
tyranny and extortion, and execrated for the deeds of his
troops, especially those of the Deless; the sheyks enjoyed
the people to close their shops, and the soldiers clamoured
for pay. At this juncture a firman arrived from Constantin-
ople conferring on Mehemet Ali the pashalik of Jiddeh;
but the occurrences of a few days raised him to that of
Egypt.

On the 12th of Safar 1220 (May 1805) the sheyks,
with an immense concourse of the inhabitants, assembled
in the house of the kadee; and the 'Ulemâ, amid the
prayers and cries of the people, wrote a full statement of
the heavy wrongs which they had endured under the
administration of the pasha. The 'Ulemâ, in answer, were
determined to go to the citadel; but they were apprised of
treachery; and on the following day, having held another
ouncil at the house of the kadee, they proceeded to
Khurshedd, and informed him that the people would no
longer submit to Khurshedd. "Then whom will ye have?"
said he. "We will have thee," they replied, "to govern
us according to the laws; for we see in thy countenance
that thou art possessed of justice and goodness." Mehemet
Ali seemed to hesitate, and then complied, and was at once
invited. On this, a bloody struggle commenced between
the two pashas. Cairo had before experienced such conflicts
in the streets and over the house-tops, but none so severe
as this. Khurshedd, being informed by a messenger of the
insurrection, immediately laid in stores of provisions and
ammunition, and prepared to stand a siege in the citadel.
Two chiefs of the Albanians joined his party, but many of
his soldiers deserted. Mehemet Ali's great strength lay in
the devotion of the citizens of Cairo, who looked on him as
their future deliverer from their afflictions; and great num-
bers armed themselves, advising constantly with Mehemet
Ali, having the sayyid 'Omar and the sheyks at their head,
and guarding the town at night. On the 19th of the same
month, Mehemet Ali besieged Khurshedd. Retrenchments
were raised, and the lofty minaret of the mosque of the
sultan Hasan was used as a battery whence to fire on
the citadel; while guns were also posted on the mountain
in its rear. After the siege had continued many days, Khur-
shedd gave orders to cannonade and bombard the town; and
for six days his commands were executed with little interrup-
tion, the citadel itself also lying between two fires. Meth-
emet Ali's position at this time was very critical; his troops
became mutinous for their pay; the sâlihâr, who had com-
manded one of the expeditions against the Ghuzza, advanced
to the relief of Khurshedd; and the latter ordered the Deless
to march to his assistance. The firing ceased on the Friday,
but recommenced on the eve of Saturday and lasted until
the next Friday. On the day following, news came of the
arrival at Alexandria of a messenger from Constantinople.
The ensuing night in Cairo presented a curious spectacle;
many of the inhabitants gave way to rejoicing, in the hope
that this envoy would put an end to their miseries, and
fire off their weapons as they paraded the streets with
bands of music. The sâlihâr, imagining the noise to be a
fray, marched in haste towards the citadel, while its
garrison saluted forth, and commenced throwing up
rocks and stones in the quarter of Arab-el-Yend, but was
repulsed by the armed inhabitants and the soldiers stationed
there; and during all this time, the cannonade and
bombardment from the citadel, and on it from the batteries
on the mountain, continued unabated.

The envoy brought a firmân confirming Mehemet Ali,
and ordering Khurshedd to repair to Alexandria, there to
await further orders; but this he refused to do, on the
ground that he had been appointed by a khâtîr-ahereef.
The firing ceased on the following day, but the troubles of
the people were rather increased than assuaged; murders
and robberies were daily committed by the soldiery, the
houses of certain sheyks were all shut and some were fired.

While these scenes were being enacted, El-Efseef was
besieging Demenhoor, and the other boys were returning
towards Cairo, Khurshedd having called them to his
assistance.

Soon after this, a squadron under the command of the
Turkish high admiral arrived in Alexandria. The pasha
despatches confirmatory of the firmân brought by the
former envoy, and authorizing Mehemet Ali to continue to
discharge the functions of governor for the present.
Khurshedd at first refused to yield; but at length, on con-
dition that his troops should be paid, he evacuated the
citadel and embarked for Rosetta.

Mehemet Ali now possessed the title of Governor of
Egypt, but beyond the walls of Cairo his authority was
everywhere disputed by the boys, who were joined by the
army of the sâlihâr of Khurshedd; and many Albanians
deserted from his ranks. To replenish his empty coffers he
was also compelled to levy exactations, principally from the
Copts. An attempt was made to ennare certain of the
boys, who were encamped north of the metropolis. On
the 17th of August 1805, the dam of the canal of Cairo
was to be cut, and some chiefs of Mehemet Ali's party
wrote, informing them that he would go forth early on that
morning with most of his troops to witness the ceremony,
inviting them to enter and seize the city, and to pay them,
stipulating for a certain sum of money as a reward.
The dam, however, was cut early in the preceding
night, without any ceremony. On the following morning,
these boys, with their memlooks, a very numerous body,
_break open the gate of the suburb El-Hoseyneeyeh, and
gained admittance into the city from the north, through
the gate called Bâb el-Futuoh. They marched along the
principal street for some distance, with kettle-drums behind
each company, and were received with apparent joy by the
citizens. At the mosque called the Ashrafieeyeh they
separated, one party proceeding to the Azhar and the
houses of certain sheyks, and the other turning to the
south, and through the gate called Bâb Zuwleyeh, where
they turned up towards the citadel. Here they were fired on by some soldiers from the houses; and with
this signal a terrible massacre commenced. Falling back
towards their companions, they found the by-streets closed;
and in that part of the main thoroughfare called Beyn-el-
Kasreyn, they were suddenly placed between two fires.
Thus shut up in a narrow street, some sought refuge in the
 collegiate mosque El-Barkookeyeh, while the remainder
fought their way through their enemies, and escaped over
the city-wall with the loss of their horses. Two memlooks
were slain in the meantime succeeded, by great exertions,
in giving the alarm to their comrades in the quarter of the
Azhar, who escaped by the eastern gate called Bâb el-
Churayeb. A horrible fate awaited those who had shut themselves up in the Barkookeyeh. Having begged for quarter and surrendered, they were immediately stripped nearly naked, and about fifty were slaughtered on the spot; and about the same number were dragged away, with every brutal aggravation of their pitiful condition, to Mehemet Ali. Among them were four boys, one of whom, driven to madness by Mehemet Ali's mockery, asked for a drink of water; his hands were untied that he might take the bottle, but he snatched a dagger from one of the soldiers and rushed at the pasha, and fell covered with wounds. The wretched captives were then chained and left in the court of the pasha's house; and on the following morning the heads of their comrades who had perished the day before were skinned and stuffed with straw before their eyes. One boy and two others paid their ransom and were released; the rest, without exception, were tortured and put to death in the course of the ensuing night.

Eighty-three heads (many of them of Frenchmen and Albanians) were stuffed and sent to Constantinople, with a boast that the Mameluk chiefs were utterly destroyed. This was the first massacre of his too confiding enemies.

The boys, after this, appear to have despaired of regaining their ascendancy, most of them retreated to Upper Egypt, and an attempt at compromise failed. El-Efie offered his submission on the condition of the cession of the Faiyum and other provinces; but this was refused, and that chief gained two successive victories over the pasha's troops, many of whom deserted to him.

At length, in consequence of the remonstrances of the English, and a promise made by El-Efie of 1500 purses, the Pasha consented to reinstate the twenty-four boys, and to place El-Efie at their head; but this measure met with the opposition of Mehemet Ali and the determined resistance of the majority of the Mamelooks, who, rather than have El-Efie at their head, preferred their present condition, for the enmity of El-Bardeesee had not subsided, and he commanded the voice of most of the other boys. In pursuance of the above plan, a squadron under Sahih Pasha, shortly before appointed high admiral, arrived at Alexandria on the 1st of July 1806, with 3000 regular troops, and a successor to Mehemet Ali, who was to receive the pashalik of Salonika. Thus wise chief professed his willingness to obey the commands of the Porte, but stated that his troops, to whom he owed a vast sum of money, opposed his departure.

He induced the 'Ulema to sign a letter, praying the sultan to revoke the command for reinstating the boys, because the chiefs of the Albanian troops to swear allegiance to him, and sent 2000 purses contributed by them to Constantinople. El-Efie was at that time besieging Demenoor, and he gained a signal victory over the pasha's troops; but the dissentions of the boys destroyed their last chance of a return to power. El-Efie and his partisans were unable to pay the sum promised to the Porte; Sahih Pasha received plenipotentiary powers from Constantinople, in consequence of the letter from the 'Ulema; and, on the condition of Mehemet Ali's paying 4000 purses to the Porte, it was decided that he should continue in his post, and the reinstatement of the boys was abandoned.

Fortune continued to favour the pasha. In the following month, El-Bardeessee died, aged forty-eight years; and soon after, a scarcity of provisions excited the troops of El-Efie to revolt. That boy very reluctantly raised the siege of Demenoor, being in daily expectation of the arrival of an English army; and at the village of Shubra-mem he was attacked by a sudden illness, and died on the 30th of January 1807, at the age of fifty-five. Thus was the pasha relieved of his two most formidable enemies; and shortly after he defeated Shabbeen Bey, with the loss to the latter of his artillery and baggage and 300 men killed or taken prisoners.

On the 17th of March 1807, a British fleet appeared off Alexandria, having on board nearly 5000 troops, under the command of General Fraser, and the place, being disaffected towards Mehemet Ali, opened its gates to them. Here Mehemet Ali first heard of the Envoy of El-Efie, upon whose co-operation they had founded their chief hopes of success, and they immediately despatched messengers to his successor and to the other boys inviting them to Alexandria. The British resident, Major Mesnet, having represented the importance of taking Rosetta and El-Bakhmeeyeh, to secure supplies for Alexandria, General Fraser, with the concurrence of the admiral, Sir John Duckworth, detached the 31st regiment and the Chasseurs Britanniques, under Major-General Wauchope and Brigadier-General Meade, on this service, and these troops encamped Rosetta without encountering any opposition; but as soon as they had dispersed among the narrow streets, the garrison opened a deadly fire on them from the latticed windows and the roofs of the houses. They effected a retreat on Abou-Keer and Alexandria, after a very heavy loss of 185 killed and 262 wounded, General Wauchope and three officers being among the former, and General Meade and seventeen officers among the latter. The heads of the slain were fixed on stakes on each side of the road crossing the Ebbebekleyeh in Cairo.

Mehemet Ali, meanwhile, was conducting an expedition against the boys in Upper Egypt, and he had defeated them near Asyoot, when he heard of the arrival of the British. In great alarm lest the boys should join them, especially as they were far north of his position, he immediately sent messengers to his rivals, promising to comply with all their demands, if they should join in expelling the invaders; and this proposal being agreed to, both armies marched towards Cairo on opposite sides of the river.

To return to the unfortunate British expedition. The possession of Rosetta being deemed indispensable, Brigadier-General Stewart and Colonel Oswald were despatched thither, with 2500 men. For thirteen days a cannonade of the town was continued without effect; and on the 30th of April, news having come in from the advanced guard at El-Hamad of large reinforcements to the besieged, General Stewart was compelled to retreat; and a dragoon was despatched to Major Macleod, commanding at El-Hamad, with orders to fall back. The messenger, however, was unable to penetrate to the spot, and the advanced guard, consisting of a detachment of the 71st, two squadrons of the 78th, one of the 35th, and De Rolles's regiment, with a piquet of dragoons, the whole mustering 753 men, was surrounded, and, after a gallant resistance, the survivors, who had expended all their ammunition, became prisoners of war. General Stewart regained Alexandria with the remainder of his force, having lost, in killed, wounded, and missing, nearly 900 men. Some hundreds of British heads were now exposed on stakes in Cairo, and the prisoners were marched between these mutilated remains of their countrymen.

The boys became divided in their wishes, one party being desirous of co-operating with the British, the other with the pasha. These delays proved ruinous to their cause; and General Fraser, despairing of their assistance, evacuated Alexandria on the 14th of September. From that date to the spring of 1811, the boys from time to time relinquished certain of their demands; the pasha on his part granted them what before had been withheld; the province of the Faiyum, and part of those of El-Geezah and Benes Suywyf, were ceded to Shabbeen; and a great portion of the Suez, on the condition of paying the land-tax, to the others. Many of them took up their abode in
Before the town of Er-Rass; but three months' went further south and exiles were attacked by Ibrahim Mehmet Bay that he thinned, they endeavored to mountain their little power by training some hundreds of blacks; but again, on the approach of Ismail, another son of the pasha of Egypt, sent with an army to subdue Nubia and Sennar, some returned to Egypt and settled in Cairo, while the rest, amounting to about 100 persons, fled in dispersed parties to the countries adjacent to Sennar.

Ibrahim Mehmet Ali, being undisputed master of Egypt, at the reiterated commands of the Porte despatched in 1811 an army of 8000 men, including 2000 horse, under the command of Toosoon Pasha, against the Wahhabees. After a successful advance, this force met with a serious repulse at the pass of Sakhir and Judeiydeh, and retreated to Yembo. In the following year Toosoon, having received reinforcements, again assumed the offensive, and captured Medinah after a prolonged siege. He next took Jiddah and Mecca, defeating the Wahhabees beyond the latter to put to and capturing their general. His arms met with various fortune; but on the whole his forces proved superior to those of the enemy. He led a successful expedition in the Hijaz, and, after concluding a treaty with the Wahhabee chief, 'Abd-Allah, in 1815, he returned to Egypt on hearing of the escape of Napoleon from Elba.

He now confiscated the lands belonging to private individuals, merely allowing them a pension for life, and attempted to introduce the European system of military tactics. A formidable mutiny, however, broke out in the metropolis, the pasha's life was endangered, and he sought refuge by night in the citadel, while the soldiery committed many acts of plunder. The revolt was reduced by presents to the chiefs of the insurgents, and Mehmet Ali very honourably ordered that the sufferers by the late disturbances should receive compensation from the treasury. The project of the "Nizam Gedeed," as the European system is called in Egypt, was, in consequence of this commotion, abandoned for a time.

Soon after Toosoon returned to Egypt, but Mehmet Ali, dissatisfied with the treaty which had been concluded with the Wahhabees, and with the non-fulfilment of certain of its clauses, determined to send another army to Arabia, and to include in it the soldiers who had recently proved unruly. This expedition, under Ibrahim Pasha, left in the autumn of 1816. After several unimportant advantages, Ibrahim sat down before the town of Er-Ras; but three months' exertions proving unavailing, he raised the siege, with the loss of nearly half his army. Notwithstanding, he advanced on the capital, Ed-Dir'eeyeh, by slow but sure steps. The last place before reaching that city offered a brave resistance, and Ibrahim, in revenge, caused all its inhabitants to be put to the sword. He came, including children, the former of whom were spared not from motives of pity. Ed-Dir'eeyeh fell after a five months' siege, in the course of which an explosion destroyed the whole of the besiegers' powder; and had the Wahhabees been aware of the extent of the disaster, few, we may believe, would have escaped to tell the tale. 'Abd-Allah, their chief, was taken, and with his treasurer and secretary was sent to Constanti

A remnant of the Memlooks fled to Nubia, and a tran

E CAIRO, but tranquillity was not secured; several times they met the pasha's forces in battle, and once gained a signal victory. Early in the year 1811, the preparations for the expedition against the Wahhabees in Arabia being complete, all the Memlook boys then in Cairo were invited to the ceremony of investing Mehmet Ali's favourite son, Toosoon, with a pelisse and the command of the army. As on the former occasion, the unfortunate Memlooks fell into the snare. On the 1st of March, Shukran Bey and the other chiefs (one only excepted) repaired with their retinues to the citadel, and were courteously received by the pasha. Having taken coffee, they formed in procession, and, preceded and followed by the pasha's troops, slowly descended the steep and narrow road leading to the great gate of the citadel; but as soon as the Memlooks arrived at the gate it was suddenly closed before them. The last of those who made their exit before the gate was shut were Albanians under Sail Kooch. To these troops their chief now made known the pasha's orders to massacre all the Memlooks within the citadel; therefore, having returned by another way, they gained the summits of the walls and houses that hem in the road in which the Memlooks were incarcerated, and some stationed themselves upon the eminences of the rock through which that road is partly cut. Thus securely placed, they commenced a heavy fire on their defenseless victims; and immediately the troops who closed the procession, and who had the advantage of higher ground, followed their example. Of the betrayed chiefs, many were laid low in a few moments; some, dismounting, and throwing off their outer robes, vainly sought, sword in hand, to return, and escape by some other gate. The few who regained the summit of the citadel experienced the same cruel fate as the rest (for those whom the Albanian soldiers made prisoners met with no mercy from their chiefs or from Mehmet Ali), but it soon became impossible for any to retreat their steps even so far; the road was obstructed by the bleeding bodies of the slain Memlooks, and their richly caparisoned horses, and their grooms. 470 Memlooks entered the citadel; and of these very few, if any, escaped. One of these is said to have been a bey. According to some, he leapt his horse from the ramparts, and slighted unhurt, though the horse was killed by the fall; others say he was prevented from joining his comrades that discovered the treachery while waiting without the gate. He fled and made his way to Syria. This massacre was the signal for an indiscriminate slaughter of the Memlooks throughout Egypt, orders to this effect being transmitted to every governor; and in Cairo itself, the houses of the bey were given over to the soldiery, who slaughtered all their adherents, treated their women in the most shameless manner, and sacked their dwellings. During the two following days, the pasha and his son Toosoon rode about the streets, and endeavoured to stop these atrocious proceedings; but order was not restored until 500 houses had been completely pillaged. In extenuation of this dark blot on Mehmet Ali's character, it has been urged that he scrupled not to defy the Porte. But who can believe, would have escaped to tell the tale. 'Abd-Allah, their chief, was taken, and with his treasurer and secretary was sent to Constantinople, where, in spite of Ibrahim's promise of safety, and of Mehmet Ali's interference in their favour, they were paraded and put to death. At the close of the year 1819, Ibrahim returned to Cairo, having conquered all present opposition in Arabia, but without having broken the spirit of the Wahhabees.
The pasha, since his return from Arabia, had turned his attention to the improvement of the manufactures of Egypt, and engaged very largely in commerce. The results of these attempts are stated in other places, but the important work of digging the new canal of Alexandria, called the Mahmooneyeh, must here be again mentioned. The old canal had long fallen into decay, and the necessity of a safe channel between Alexandria and the Nile was much felt. Such was the object of the canal then excavated, and it has on the whole well answered its purpose; but the sacrifice of life was enormous, and the labour of the unhappy fellahs was forced. Towards the accomplishment of a favourite project, the formation of the Nizam Godeed, a force was ordered to the southern frontier of Egypt, and the conquest of Sennâr was contemplated in order to get rid of the disaffected troops, and to obtain a sufficient number of captives to form the nucleus of the new army. The forces destined for this service were led by Isma'il, then the youngest son of Mehemet Ali; they consisted of between 4000 and 5000 men, Turks and Arabs, and were despatched in the summer of 1820. Nuba at once submitted, and Shâgöeyeh Arabs immediately beyond the province of Dongola were worsted, and Sennâr was reduced without a battle. Mohammad Bey, the defender, with another force of about the same strength, was sent by Mehemet Ali against Kordufan with a like result, but not without a hard-fought engagement. In 1822 Isma'il was, with his retinue, put to death by an Arab chieftain named Nimur; and the defender, a man infamous for his cruelty, assumed the command in those provinces, and exacted terrible retribution from the innocent inhabitants.

In the years 1821 and 1822 Mehemet Ali despatched both ships and men (the latter about 7000 or 8000 Albanians and Turks) to the Morea, Cyprus, and Candia, to aid the Porte in reducing the Greek insurrection; and he continued to take part in that struggle, his fleet being engaged at Navarino, until the English insisted on the evacuation of the Morea in 1828 by Ibrahim Pasha. In 1823 an army of disciplined troops was at length organized. 8000 men (chiefly slaves, from Sennâr and Kordufan) were trained by French officers at Asswân. Of the vast numbers seized in the countries above named, many died on the way; those who were not eligible were, with the women, sold in Cairo, and in the remainder were incorporated many fellahs. Colonel Sêves (Suleyman Pasha), a Frenchman who after wards became a Moslem, superintended their organization, great numbers of the blacks died, but the Egyptians proved very superior. Many thousands were pressed in consequence, and they now constitute the bulk of the army.

In 1823 the new conscripts amounted to 24,000 men, composing six regiments of infantry, each regiment consisting of five battalions of 800 men, and the battalions of eight companies of 100 men.

In 1824 a native rebellion of a religious character broke out in Upper Egypt, headed by one Ahmad, an inhabitant of El-Salîmeyeh, a village situates a few miles above Thebes. He proclaimed himself a prophet, and was soon followed by between 20,000 and 30,000 insurgents, mostly peasants, but some deserters from the Nizâm, for that force was yet in a half-organized state and in part declared for the impostor. The insurrection was crushed by Mehemet Ali, and about one-fourth of Ahmad's followers perished, but he himself escaped and was never after heard of. Few of those unfortunates possessed any other weapon than the long staff (labour) of the Egyptian peasant; still they offered an obstinate resistance, and the combat resembled a massacre. In the same year was once more made on the Wahhabees, who had collected in considerable numbers. The 2d regiment was sent on this service, and it behaved in a very creditable manner.

But the events of the war with the Porte are perhaps the most important of the life of Mehemet Ali. The campaign of 1831 had ostensibly for its object the pacification of 'Abd-Allah, pasha of Acre, the invading force consisted of six regiments of infantry, four of cavalry, four field-pieces, and a greater number of siege-guns, the whole under the command of Ibrahim Pasha, while the fleet, conveying provisions, ammunition, &c., was to accompany the army by sea. The terrible cholera of 1831, however, stayed the expedition when it was on the eve of departing, 5000 of its number died, and it was not until early in October of the same year that it started. Little opposition was encountered on the way to Acre, whether Ibrahim had gone by sea, and that place was invested on the 29th of November. The artillery of the besieged was well served, and an assault in the following February was repulsed, and the cold and rain of a Syrian winter severely tried the Egyptian troops. A second assault in like manner failed, and Ibrahim was called away to repel Osman Pasha, governor of Aleppo. The latter, however, hastily decamped without giving him battle, and Ibrahim, deeming this advantage sufficient, retraced his steps towards Acre. He then pushed the siege with fresh vigour, and stormed the city on the 27th of May, 1400 men fell in the breach, and the garrison was found to be reduced to about 4000 men. The fall of Acre was followed by negotiation. Mehemet Ali evinced a disposition for peace, but demanded the government of Syria, and the Porte, in consequence, denounced him as a traitor. On his part, Ibrahim pushed his successes; Damascus was evacuated at his approach, and the battle of Hums, fought on the 5th of July 1832, decided the superiority of the Egyptian army, and the advantage of disciplined troops over an irregular force, although very disproportionate in numbers. The enemy composed the advanced guard of the Turkish army, 30,000 strong, and the Egyptians numbered only 16,000 men.

After this victory, Ibrahim marched to Hamah, and thence to Aleppo (which had just before closed its gates against the Turkish general-in-chief, Hoseyn Pasha, whose troops became rapidly disorganized), forced the defiles of Beylân, and pursued the fugitive Turks to Adaneh. About the same time an Egyptian squadron had chased the sultans fleet into Constantinople. Diplomacy was, at this point, again resorted to, but without any result, the sultan depended on his fleet to protect the capital, and determined to risk another engagement with the victorious enemy. The charge of this venture was intrusted to Ibrahim Pasha, the grand vizir. In the meantime, Isma'il Pasha had gained the pass of Taurus, and having beaten the Turks at Oulou-Kialakh, he hesitated not to give battle to Rezedd Pasha at the head of about 60,000 men, his own army being less than half that strength, the battle of Kounuyeh, on the plains of Anatolia, proved utterly disastrous to the Porte; in the confusion of the fight, and the darkness of a thick day, the grand vizir was made prisoner, his army routed, and Constantinople was within six marches of the victor, without an army to oppose his passage.

The capital of the Ottoman Empire, in imminent danger by sea and land, was then intrusted to the keeping of its hereditary enemy, as the last resource of the sultan Mahmood, and a Russian fleet and army were sent thither. Negotiations were in consequence opened, and on the 14th of May 1833 a treaty was concluded between Mehemet Ali and the Porte, by which the whole of Syria and the district of Adaneh were ceded to the former, on condition of his paying tribute. With that terminated the war, but not the animosity of the sultan. Ibrahim, by excessive firmness and rigour, speedily restored security and tranquillity to the greater part of Syria; but some years later, the attempt of Mahmood to get the better of his vassal, and the consequent
disaster experienced by his arms at Nezzeb, entailed fresh complications, and the interference of Great Britain ended in the restoration of Syria to the Porte in 1841. Mehemet Ali had placed all his reliance on the co-operation of France, and to its desertion of his cause, and his confidence in its assistance, either moral or material, must be ascribed the unfortunate issue of the war. That the Syrians, in general, preferred, the rule of Mehemet Ali to the tyranny of pashas appointed from Constantinople may be safely ascertained; but we cannot close this account of his possession of that province without animadverting on the horrible cruelties perpetrated by Ibrahim Pasha, or warning our readers not to give credence to the unmeasured praise bestowed by many on the Egyptian troops there engaged. Concealing that they were superior soldiers to the Turks, it must be borne in mind that they were veterans, disciplined and led by the French officers and an able general; their opponents were destitute of any European discipline, badly officered, and discouraged by the disasters in Greece. It has, moreover, been stated on good authority, that Ibrahim owed much of his success to the placing of artillery in the rear of his troops, with orders to fire on them should they show symptoms of wavering.

After the peace of 1841 Mehemet Ali gave up all great political projects, and seated himself in improved, real or imaginary, in Egypt. He continued to prosecute his commercial speculations, and manufacturing, educational, and other schemes. The barrage of the Nile, still incomplete, was commenced by his direction, and in 1847 he visited Constantinople, where he received the rank of vizir. In the year 1848, however, symptoms of insubordination appeared; and after a short space Ibrahim was declared his successor, but died after a brief reign of two months.

Mehomet Ali survived Ibrahim, and died on the 3d of August 1849. Many and conflicting have been the opinions entertained of this remarkable man; for such at least all acknowledge him to have been. His massacre of the Memlouks has been the great point of attack by his enemies; but that, as well as many of his other acts, must be ascribed to his boundless ambition, not to inordinate cruelty, for he proved himself to be averse to unnecessary bloodshed. This has really esteemed European civilization may be doubted; but his intelligent mind could not fail to perceive that therein lay his great strength, and of this he availed himself with consummate ability. To his firm government Egypt is indebted for the profound tranquility which it has long been its good fortune to enjoy. A traveller of any nation or faith may traverse it in its length and breadth with greater safety than almost any other country out of Western Europe; and the display of fanaticism has been rigorously punished. While, however, Egypt has benefited by the establishment of order, the people have suffered most severe excstractions. The confiscation of private lands has been before mentioned; to that arbitrary act must be added the seizure of the lands of the mosques, the imposition of heavy taxation, and a system of merciless impressment. In fact, the condition of the Egyptian feliah has rarely been so wretched as it is at the present day. Mehemet Ali also misunderstood the real resources of Egypt, which are certainly agricultural; he dealt a severe blow to native produce by endeavouring to encourage manufacturing industry, and by establishing enormous Government monopolies, a measure which crushed the spirit of the agriculturists. His military and governing abilities were assuredly very great; his career is almost unequalled in Turkish history. Had it not been for the intervention of Great Britain, his Syrian successes over the Porte would probably have rescued Egypt from the wretched condition of a Turkish province. But the firmán of 1841 entailed the loss of all his military power, the army was reduced to 18,000 men, and the navy condemned to rot in the harbour of Alexandria; while Mehemet Ali, failing to gain the great object of his ambition, the establishment of an independent dynasty, and being compelled to look on his then living family as his only heirs, thenceforth confined himself to measures of loss improvement, and did not prosecute even those with his former energy.

The entire constitution of the government of Egypt is the work of Mehemet Ali. With a few exceptions, he destroyed all former usages, and introduced a system partly derived from European models. The army and navy are of his creation, so are the taxation, the regulation of import and export duties, &c., quarantine laws, the manufacturers, colleges, and the ministry. Some of these institutions are useful, others both vexatious and ill-calculated for the country. The colleges of languages and medicine, and the printing-press at Boulak, are among the former, and are exceedingly praiseworthy in a right direction; and in the same category must be placed many minor improvements, in which Mehemet Ali showed himself to be far in advance of his countrymen; while, weighing his chequered life and numerous disadvantages of position and nation, his prudent character, enlightened mind, and distinguished ability must place him high among the great men of modern times.

Ibrahim was succeeded by his nephew 'Abd Allah, son of Tawfik. This miserable voluptuary, and wilful bigoted though ignorant Mussulman, utterly neglected the affairs of government and solely consulted his own gratification. During his reign all the great works begun by Mehemet Ali were suspended. It was a time of deliberate retrogression, and his sudden death in July 1854 was welcomed by all true Egyptians as the removal of the country's curse. His successor, Said Pasha, the fourth son of Mehemet Ali, endeavoured to pursue his great father's policy and to carry out his aims. He had not, however, the strength of character or the health needed to meet the serious difficulties of the task, and he will chiefly be remembered for the abolition of some of the more grinding Government monopolies, and for the concession of the Suez Canal. It was reserved for his nephew, the present khedive, to attain all and more than that Mehemet Ali had designed for his country.

The reign of Ismail promises to be the beginning of a new era for Egypt. A man of undoubted ability, possessed of unusual energy in administration, fully appreciative of the importance of Western civilization, fired with the ambition proper to a grandson of Mehemet Ali, the khedive is a ruler such as Egypt has scarcely seen since the Arab conquest. His first step was to remove, as far as possible, the irksome control of the Porte. At great cost he obtained an imperial firmán in 1866, removing almost all the old treaty restrictions, granting him the title of khedive.

Having thus obtained for himself and his dynasty a settled regal rank, Ismail turned his attention homewards, and began a series of reforms such as no previous governor of Egypt ever contemplated. He re-established and improved the administrative system organized by Mehemet Ali, and which had fallen into decay under 'Abdah's indolent rule; he caused a thorough remodeling of the customs system, which was in an anarchic state, to be made by English officials; in 1865 he bought the Egyptian post-office, and placed it under the direction, with full powers, of an official from St. Martin's Land, who has brought it into admirable working order; he reorganized the military schools of his grandfather, and lent his willing support to the cause of education in every way. Public works have largely engaged the attention of the khedive. Railways, telegraphs, lighthouses, the harbour works at Suze, the breakwater at Alexandria, have been carried out under his personal auspices by some of the best contractors of Europe. If there is a fault to be found in this Europeanizing of Egypt, it is that the practical zeal for modern civilization leaves no room for the honourable respect due to the unique antiquities of the country. It is true that ancient Egypt is protected by the care of Mariette Bey, but the art of the Arabs is suffered to decay, may, as is even purposely demolished, to make room for modern French gewgaws. A recent writer tells us that a new street cuts through about a mile of the "old Arab rookeries," and gravely advances the opinion that the opera house and the public gardens and the other meretricious abominations that have been set up in Cairo are worthy of a second-class European city! Still, terrible as is the vandalism now going on in Egypt, there can be little doubt that the present policy of the khedive will add greatly to the prosperity and health of the people. At the same time, future generations will gain at the fearful expense of the present. The funds required for these public works, as well as the actual labour, have been remorselessly extorted from a poverty-stricken population; and there is probably no peasant now existing whose condition is worse than that of the long-suffering Egyptian fellah.

One of the greatest reforms that Egypt owes to its present ruler is the abolition of the old system of consular jurisdiction, and the substitution of mixed courts, where European and native judges sit together to try all mixed cases without respect to nationality. These courts were established in 1874 on the suggestion of the wisest of Egypt's statesmen, Nubar Pasha, and on the recommendation of an international commission. A code based on the Moham­medan law and the Code Napoleon has been drawn up, which seems thoroughly suited to the needs of the position; and the best results may be looked for from this reform. It was greatly to be desired that the jurisdiction of those courts should be extended so as eventually to supersede the old native system. At present they only take the place of the consular courts.

In recent times the khedive has annexed a large territory to the south of Kharthoum, now extending about as far as Goudokoro, and which will doubtless shortly include the lakes of Victoria and Albert Nyanza. The expedition was at first commanded by Sir Samuel Baker, with very unsatisfactory results; and great relief was felt when the continuance of the war of conquest was intrusted to Colonel Gordon, an officer in whose character and ability the fullest confidence is placed. The khedive has professed himself anxious to put down the Nile slave-trade, and that he is really desirous of seeing the traffic ended is shown by the full powers he has given Colonel Gordon for the suppression of it in the heart of the slave-country. What the result will be it is hard to foretell; but the good faith of the khedive and the determination of Colonel Gordon are now beyond a doubt. Quite recently (Aug. 14, 1877) a convention between the British and Egyptian Governments for the suppression of the slave-trade has been signed, imposing stringent penalties on the importation of slaves into Egypt, and extending the power of search in the case of suspected vessels.

Altogether it may be believed that a better time is beginning for Egypt. (E.B.—S.L.P.)

TOPOGRAPHY AND MONUMENTS 1

The northern coast of Egypt is low and barren, presenting no features of interest, and affording no indication of the character of the country which it bounds. It is a barrier, generally of sand-hills, but sometimes of rock, for the most part wholly destitute of vegetation, except where grow a few wild and stunted date-palms. Immediately behind are desolate marshy tracts or extensive salt lakes, and beyond, the fertile country. The last is a wide plain, intersected by the two branches of the Nile, and by many canals, of which some were anciently branches of the river, and having a soil of great richness, though in this particular it is excelled by the valley above. The only inequalities of the surface are the mounds of ancient towns, and these, often if not always ancient, on which stand the modern towns and villages. The palm-trees are less numerous, and not so beautiful as in the more southern part of the country, but other trees are more common. The houses and huts of the towns and villages are of burnt brick near the Mediterranean; but as the climate becomes drier, and the occurrence of rain far less frequent, the use of crude brick obtains, until near the point of the Delta it is very general. The mosques even of the towns are rarely remarkable for architectural beauty in the tract to the north of Cairo. The palaces or villas of the Turkish grandees, which are not uncommon, have, however, a light and picturesque appearance, though their style is not good. The deserts which inclose the plain on both sides are rocky tracts of very slight elevation, having their surface overspread with sand and other debris.

Of the towns on the northern coast, the most western, Alexandria, called by the natives El-Fakendoroeyeh, is the largest and the most important. It was founded in the year B.C. 332 by Alexander the Great, who gave it the form of a Macedonian network, and by many moderns it is considered that country.

The island of Pharos was likewise inhabited, and was joined to the continent by the mole called the Heptastadium. The Heptastadium and the island divided the bay into two harbours. These were spacious, and although the western, anciently called Portus Eunocci, but now the Old Port, is difficult to enter, and the eastern, Magnus Portus, or the New Port, is not so deep and is less secure, they are, except for Said, by far the best anchorage on this coast of Egypt.

Alexandria, which partly occupied the site of the ancient Rhacotis, a place of little importance, naturally speedily increased in consequence, and became the emporium of the trade between Europe, Arabia, and India. After the death of Alexander the city became the capital of the Ptolemies. By the Ptolemies Alexandria was adorned with palaces and

1 The following account of the topography and monuments of Egypt is mainly based on Mr. Lane's MS. "Description of Egypt," which the writer of this article used as his guide to the monuments during his residence in that country.
of great magnificence, for which they did not scruple to
despoil more ancient edifices of some of their choicest orna-
ments. While its commercial importance increased, it
became a celebrated seat of learning, with the greatest
library of antiquity, through the wise interest with which
the Greek kings regarded science and letters. Under the
Ptolemies, however, the inhabitants, who were chiefly
Greeks, became very troublesome to their rulers, like most
commercial populations, and their turbulence was ill
restrained by the weakness of the later sovereigns of that
line. From the time of the Roman conquest, B.C. 30, until
it was taken by the Arabs, A.D. 641, Alexandria sensibly
declined, partly in consequence of its being a provincial
capital, instead of a royal residence, but chiefly because of
the unvarying disposition of its inhabitants, and their violent
religious and political disputes, which at last resulted in
the seat of government being transferred to the fortress of
Egyptian Babylon, near the modern Cairo, which became
in some sort the capital. During this period it had been
distinguished for the learning of its ecclesiastics, and the
strong part which they took in the theological disputes
of the early church. Under the Muslims Alexandria never
regained the position of metropolis of Egypt, and its
importance, with some fluctuations, waned until the dis-
cover and consequent adoption of the route to India by
the Cape of Good Hope almost withdrew the main cause
of its prosperity. Recently, however, the resumption of
the overland route has greatly benefited this city, and
although it was not made the capital, it became the favourite
residence of Mehemet Ali, which in like manner contributed
to its welfare.

The older part of the town of Alexandria stands upon the
Heptastadium, now much wider than it was anciently; but
the recent part, where are the houses of the European mer-
chants, occupies the site of a portion of the ancient city,
which was nearest to the mole. The most striking edifice is
the castle on the island of Pharos, containing a lighthouse,
which has succeeded to the more famous Pharos of antiquity.
Here also is the pasha's palace, as well as a lesser Pharos.
The houses of the town are built of stone, or have their
lowest story cased with that material, and the portion
above built of brick plastered and whitewashed. The
residences of the European merchants and consuls and
the houses of Turks and natives are spacious and well-buil-
建构的，像在现代意大利风格，但没有要求

To the east of Alexandria, the first place of
importance is El-Rashed, called by the Europeans Rosetta,
a considerable town on the west bank of the Rosetta branch
of the Nile, anciently the Bobstine. Before the cutting
of the Moehemel All of the Mahnemohon Canal to connect
Alexandria with this branch of the river, Rosetta was a
place of greater importance than now, as in consequence of
the decay of the old canal of Alexandria, the overland trade
from India chiefly passed through it. It is a well-built
town, having some gardens, and is in many respects
more agreeable than Alexandria. Its population is stated
to be 15,000. A little to the north of the town is the
bogház, a bar of sand stretching across the mouth of
the river, and rendering it often impassable; and between
it and Rosetta is an old fort called Fort St Julian by the
French, who repaired it during their occupation of Egypt,
when one of their officers discovered the Rosetta Stone,
the famous trilingual tablet which afforded the clue by
which hieroglyphics were interpreted.

In ascending the Rosetta branch, the first place of
interest is the site of Sais, satis, on the eastern bank, marked
by lofty mounds, and the remains of massive walls of crude
brick, in one of which are those of a great enormous pillar,
the chief temple and doubtless other sacred edifices stood.
The goddess Nit or Neith was the divinity of the place, and a
great festival was annually held here in her honour, to
which pilgrims resorted from other parts of Egypt. Sais
was remarkable for the learning of its priests, and was the
royal residence of the Saite kings (Dynasties XXIV., XXV.)
A modern village here is called “Sâ-el-Hagar,” or “Sâs of the
Stone,” a name which perhaps alludes to the famous
monolith described by Herodotus.

In the interior of the modern Delta no remains of import-
ance have been discovered, though there are many ancient
sites marked by mounds. The chief towns are El-Mahalla
el-Kebeereh, not far from the Damietta branch, about forty
miles from the sea; Tantâ, nearly in the middle of the
Delta; and Manoof, farther south. Of these Tantâ is best
known as the birth-place of a Muslim saint, the seyiyd
Ahmad El-Bedawee, in whose honour three festivals are
annually kept, the greatest of which attracts more
pilgrims than any other in Egypt, and is in this respect second
alone to the pilgrimage to Mecca. The festivals of Tantâ
are rather distinguished by riot than piety, and recall the
revelries of Bubastis and Canopus.

Several places of interest are found on the course of the
Damietta branch, the old Phatnatic or Pathmetic. First
of these is the town whence

Thothmes III., Ramses II., and a later king. Beside it

It was taken by the Arabs, A.D. 641, Alexandria sensibly
declined, partly in consequence of its being a provincial
capital, instead of a royal residence, but chiefly because of
the unvarying disposition of its inhabitants, and their violent
religious and political disputes, which at last resulted in
the seat of government being transferred to the fortress of
Egyptian Babylon, near the modern Cairo, which became
in some sort the capital. During this period it had been
distinguished for the learning of its ecclesiastics, and the
strong part which they took in the theological disputes
of the early church. Under the Muslims Alexandria never
regained the position of metropolis of Egypt, and its
importance, with some fluctuations, waned until the dis-
cover and consequent adoption of the route to India by
the Cape of Good Hope almost withdrew the main cause
of its prosperity. Recently, however, the resumption of
the overland route has greatly benefited this city, and
although it was not made the capital, it became the favourite
residence of Mehemet Ali, which in like manner contributed
to its welfare.

The older part of the town of Alexandria stands upon the
Heptastadium, now much wider than it was anciently; but
the recent part, where are the houses of the European mer-
chants, occupies the site of a portion of the ancient city,
which was nearest to the mole. The most striking edifice is
the castle on the island of Pharos, containing a lighthouse,
which has succeeded to the more famous Pharos of antiquity.
Here also is the pasha's palace, as well as a lesser Pharos.
The houses of the town are built of stone, or have their
lowest story cased with that material, and the portion
above built of brick plastered and whitewashed. The
residences of the European merchants and consuls and
the houses of Turks and natives are spacious and well-buil-

of granite, and its shaft is about 70 feet high, the whole
column being nearly 100 feet in height. Its pedestal bears a
Greek inscription in honour of the emperor Diocletian.

Proceeding to the east of Alexandria, the first place of
importance is El-Rashed, called by the Europeans Rosetta,
from Syene, a distance by the river, on which they were doubtless floated, of more than 600 miles. Bearing in mind this circumstance, and the difficulty of both working and sculpturing so hard a material, this temple must be considered to be one of the most costly in the country. The earliest name which has been found here is that of Nekht-har-heap (Dynasty XXXX.), but the most common one is that of Potomry Philadelphus. A little to the south of this site, on the same bank, is the small town of Semnnon, anciently Sobennytus, and a short distance farther, on the same side, is the village of Aboo-Seer, the ancient Busara named after Oasirs, who, with Iss, was here worshipped. Herodotus mentions among the great festivals that of Iss he held at Busara, but this was more probably kept at Iseum, which was not far. For a long distance there is nothing of interest until we reach Tel-Atreeb, where the site of the town of Athribus is marked by high mounds, with remains of ancient houses and some blocks of stone.

To the eastward of the Dammitra branch, in the broad cultivated tract or the desert beyond, are some places worthy of note. The most eastern of these is the site of Pelusium, which was, in the times of the Pharaohs of Dynasty XXVI., the key of Egypt towards Palestine. No important remains have been discovered here. Between this site and the Dammitra branch are the mounds of Tuna, or Zoon, ZAN, ZAB, where are considerable remains of the great temple, the most remarkable of which are several fallen obelisks, some of which are broken. From their inscriptions and those of other blocks, it has been ascertained that the temple was as ancient as the time of Dynasty XII., and was much beautified by Ramses II. and other kings of that time and the subsequent period. Tuna was on the eastern bank of the Tanite branch of the Nile, now called the Canal of El-Mo'izz. On the same side of the same branch, but far to the south, was the city of Bubastis, PE-BAST, the site of which is indicated by very lofty mounds, in which may be traced the remains of its great temple, which was entirely of red granite. Here was held the festival of the goddess Bast, or Bubastis, which attracted great crowds of pilgrims, and is ranked by Herodotus first of the festivals of Egypt. Not far south, and on the borders of the desert, is Bilbeys, which was a place of some importance as a frontier-town in the time of the Eyoyoee princes. Still farther south are the mounds of Omron, the Jewish city founded by the high priest Onas, which was a temple closed by Vespasian not long after the overthrow of Jerusalem. The site is called Tell-al-Yahoodieyeh, or "The Mound of the Jewess."

At the point of the Delta is the unfinished barrage, which, by crossing both branches of the river, will regulate the inundation above and below this point. The river here becomes broader than in its divided state, and long continues so. A little south of the point of the Delta, on the eastern bank of the river, near the village of El-Matarieyeh, not far north of Cairo, is the site of the ancient Helopolis, or On, AN, the City of the Sun, marked by a solitary obelisk, and eruda brick rucles formed by the ruins of a massive wall. The obelisk bears the name of Userteran, the second king of Dynasty XII., in the simple inscription which runs down each of its sides. It is of red granite, and nearly 70 feet in height. The city was famous rather for the learning of its colleges than for its size, and the temple of the sun was held in high veneration. Many famous Greek philosophers studied here, and much of their earliest knowledge of natural science was no doubt derived from their Egyptian instructors.

Boolak, the port of Cairo, is a flourishing town, having two remarkable mosques. It was built A.H. 713, in the reign of the sultan Mohammed Ibn Kal'a-un. Here M. Mariette has founded the national "Musée Boulaq," a splendid collection of Egyptian antiquities.

Cairo is the fourth Muslim capital of Egypt, the site of one of those that have preceded it, for the most part, included within its walls, while the other two were a little to the south. 'Amr, the Muslim conqueror of the country, founded El-Fustat, the oldest of these, close to the fortress of Egyptian Babylon, the seat of government at that time. Its name signifies "The Tent," as it was built where 'Amr had pitched his tent. The new town quickly became a place of importance, and was the residence of the Nahiya, or levies, appointed by the orthodox and Ommade caliphs. It received the name of Masr, properly Miur, which was also applied by the Arabs to Memphis and to Cairo. It declined after the foundation of El-Kahireh, but never became altogether deserted, for a small town, called Masr El-Ateekah, or "Old Masr," occupies, in the present day, part of what was its area in time of prosperity. Shortly after the overthrow of the Ommade Dynasty, and the establishment of the 'Abbasides, the city of El-'Askar was founded (A.H. 133) by Sulayman, the general who subdued the country, and became the capital and the residence of the successive levies of the 'Abbasid caliphs. El-'Askar was a small town adjacent to El-Fustat, of which it was a kind of suburb. Its site is now entirely desolate. The third capital, El-Kutbat, or El-Khatib, was founded about A.H. 269, by Ahmad Ibn-Tooloon, as his capital. It continued the royal residence of his successors, but not long after the fall of the dynasty, and the subsequent Khilafahs, the seat of government was transferred by the Fatimides to a new city, El-Kal'ah, which had been sacked on the overthrow of the Tooloons, rapidly decayed. A part of the present Cairo occupies its site, and contains its great mosque, that of Ahmad Ibn-Tooloon.

Gohar El-Kaud, the conqueror of Egypt for the Fatimides caliph El-Mo'izz, founded a new capital, A.H. 385, which was named El-Kahireh, that is, "the Victorious," a name corrupted into Cairo. This town occupied about a fourth part, the north-eastern, of the present metropolis. By degrees it became greater than El-Fustat, and took from it the name of Masr, or Miur, which was applied to it by the modern Egyptians. It continually increased, so as to include the site of El-Katayeh, but not long after the fall of the dynasty, and the subsequent Khilafahs, the seat of government was transferred by the Fatimides to a new city, El-Kal'ah, which had been sacked on the overthrow of the Tooloons, rapidly decayed. A part of the present Cairo occupies its site, and contains its great mosque, that of Ahmad Ibn-Tooloon.

tion.) Sir Gardner Wilkinson, in his Modern Egypt and Thebes (t. 256), published in 1845, gives the population at about 290,000; and Mrs Poole, writing in 1842, estimates it at about 240,000 (Englishwoman in Egypt, i. 136); but Clot-Bey (Aperçu Général, i. 204), whose work appeared in 1840, states the much higher amount of about 300,000 souls. The census of 1847–8 states the more moderate number of 293,841 inhabitants, and the rest, strangers from various countries. The adult male population was about one-third of the whole, or 80,000 persons, of whom 30,000 were merchants, petty shopkeepers, and artisans, 20,000 domestic servants, and 15,000 common labourers, porters, &c.; the remainder chiefly consisting of military and civil servants of the Government. (Modern Egyptians, l. c.)

Of the most remarkable in conventionalized foliage. Like its contemporary Gothic, it has three great periods, those of growth, maturity, and decline. Of the first, the mosque of Ahmad Ibn-Tooloon in the southern part of Cairo, and the three great gates of El-Kahirah (the old city), the Bab-en-Nasr, Bab-el-Futooh, and Bab-Zuweyleh, are splendid examples. The leading forms are simple and massive, with in the mosque horse-shoe arches. The decoration is in fountains, and its details of conventionalized foliage. The second period passes from the highest point to which this art attained to a luxuriance promising decay. The mosque of Sultan Hassan, below the Citadel, those of Mueiyad and Kalâ-oon, with the Barkookeyeh, in the main street of the old city, and the mosque of Barkook in the Cemetery of Kâit Bey, are instances of the earlier and best style of this period. The forms, though still massive, are less simple, and they are admirably adapted to the necessities of space. The decoration is in conventionalized foliage, the most free forms, balanced by exquisite geometrical patterns. Of the last style of this period, the Ghoooreeyeh, in the main street of the old city, and the mosque of Kâit Bey in his cemetery, are beautiful specimens. They show an elongation of forms and an excess of decoration in which the florid qualities predominate. Of the age of decline the finest monument is the mosque of Mohammad Bey Abou-Dubab, in the old city. The forms are now poor, though not lacking to grandeur, and the details are not as well adjusted as before, with a want of mastery of the most suitable decoration. The usual plan of a congregational mosque is a large, square, open court, surrounded by colonnades, of which the chief, often with more rows of columns, faces Mecca (eastward), and has inside its outer wall a decorated niche to mark the direction of prayer. In the centre is a fountain for ablutions, often surmounted by a dome, and in the eastern colonnade a pulpit and a desk for readers. When a mosque is also the founder's tomb, it has a richly ornamented sepulchral chamber. Of domestic architecture there are a few precious fragments before the age of decline; but most specimens are of the latest period of that age. These are marked by a singular fitness and great elegance in the interiors. The decoration, though inferior to that of the mosques of the best style, is charming for variety and beauty of pattern. See Cairo, and also Architecture, vol. ii, pp. 445–44.

To the east of Cairo is a bold spur of the mountains known as El-Gebez El-Mukattam. Beneath it, and to the north of the Citadel, is the Cemetery of Kâit Bey, remarkable for the splendid tombs of the Memlooks sultans. The most beautiful of these is that of Kâit Bey, from which the cemetery takes its name, but those of the sultan Barkook and of El-Ghooreeyeh must not be passed by unmentioned. At a little distance to the north-east is the Gebel-el-Ahmar, or "Red Mountain," and southward of this, petrified wood in large quantities is seen strewn on the surface of the desert. The space between Cairo and the Nile, varying from a mile to a mile and a half in breadth, is occupied by plantations which were made by Ibrahim Pasha, during his father's rule. Formerly this side of the city was, as the other three are still partially, bounded by lofty mounds of rubbish, these he caused to be removed, and by dong so conferred a great benefit upon the inhabitants, as well as by planting with trees the intervening space. By irrigating this tract very freely with a steam-engine he considerably lessened the good he had effected, rendering the western part of the city somewhat damp. To the south of Cairo is a great cemetery containing the tomb of the Imam Esh-Shafe'ee, and also an aqueduct, built by the sultan El-Ghooreeyeh, which conducts water from the Nile to the Citadel; and further south, the Roman fortress of Egyptian Babylon, now called Kaa-es-Sheem, at present chiefly occupied by a Coptic convent, as well as the small town of Mar El-Ateekah, which is all that remains of the famous metropolis El-Fustât. It contains no remarkable edifices: in its immediate neighbourhood, however, is the oldest mosque in Egypt, that of 'Amr, the Muslim conqueror, but it has been so frequently repaired and almost rebuilt that it is impossible to form any idea of its original appearance. Opposite to Mar El-Ateekah, from which it is separated by a very narrow branch of the Nile, is the island of Er-Rodâh, containing the famous Mîkûya, or Nilometer.

The chief place on the western bank near Cairo is the small town of El-Gebez, opposite Mar El-Ateekah. El-Gebez is best known as having given its name to the most famous group of Pyramids, the chief monuments of Memphis, which stand on the slightly elevated border of the low Libyan range, not more than a quarter of a mile beyond the limit of the cultivated land.

The city of Memphis, seen, "the good station," stood on the western bank of the Nile about ten miles above Cairo. It was founded by Memnon, the first king of Egypt. The kings and people who dwelt there chose the nearest part of the desert as their burial-place, and built tombs on its rocky edge, or excavated them in its sides. The kings raised pyramids around which their subjects were buried in comparatively small sepulchres. The pyramids were grouped together, and often there is a long distance from one group to another. Although many pyramids have been nearly or wholly destroyed, yet, as the largest undoub-
PYRAMIDES

EDGY

Like wise small ones, were tombs of kings. Each had its name and extended, if we measure from the ruined Pyramid of Abou-Haweyah, somewhat to the north of those of El-Geesheh, to the southernmost Pyramid of Dahaboor, throughout a space of nearly twenty miles, in almost every part of which some sepulchres have been discovered, while it cannot be doubted that many more await a fortunate explorer.

The road to the pyramids of El-Geesheh from the town is through cultivated fields diversified by villages in palm-groves. As we approach them, these structures do not give us that idea of size that we had expected from our first distant view; and until we stand at their feet we do not appreciate their vastness. But as we endeavour to scan the height of the Great Pyramid, when about to begin its ascent, we fully realize a result that human labour has not achieved elsewhere. The very dimensions (a height of about half a thousand feet, four sides each measuring the square of a mile) set in themselves gigantism; but when we know that this huge space is almost solid, containing a few chambers so small as not to be worthy of consideration in calculating its contents, we discover that no monuments of man's raising elsewhere afford any scale by which to estimate its greatness. The Pyramids, except one or more small ones, were tombs of kings. Each had its name and a priest attached to it, for whose functions there was a chapel at some distance in front of the entrance.

The Great Pyramid, "the Splendid," was the mausoleum of Khufu, or Cheops, of Dynasty IV. The present perpendicular height of the structure is, according to General Vyse, 450 feet 9 inches, and the side of its present base 746 feet. It is about 30 feet lower than it was originally, in consequence of the casing stones and much of the outer masonry having been torn off; and its base is likewise smaller. General Vyse gives the former height at 480 feet 9 inches, and the side of the former base at 764 feet. Like all the other pyramids, it faces the cardinal points. At the completion of the pyramid the faces were smooth and polished, but now they present a series of great steps formed by the courses of stone, and are in some places (particularly in the middle of each facet, and at the angles, and about the entrance) much broken. The ascent is easy though fatiguing, and the traveller is amply rewarded by the view which he obtains from the platform, about 33 feet square, at the summit. The prospect of the fertile plain and valley on the one side, and of the undulating barren surface of the Great Desert on the other, as well as of the pyramids and tombs beneath, is alike remarkable from its character and the associations which it calls up. The examination of the interior is no less interesting. All our information about the Memphis pyramids, and those which were simply pits, were not closed, the upper chamber being intended for the performance of funeral rites when the family of the deceased visited his sepulchre. These pyramids, however, were most carefully closed. The chambers, which contained the bodies of the king, and of those (doubtless of his family) who were sometimes buried in the same structure, are without sculpture, and scarcely ornamented in any way, being usually wholly plain. The passages leading to them are only large enough to admit a sarcophagus, and after the king's burial were closed by the lowering of heavy stone portcullises, and the blocking up of the entrance. The desired object was security, and we must not, therefore, expect beauty or grandeur in chambers constructed for this purpose, although we cannot fail to admire their massive and gloomy aspect.

The entrance of the Great Pyramid is not far from the middle of the northern face, 49 feet in perpendicular height from the base. The fallen stones and rubbish have, however, raised a mound which reaches near the entrance, the masonry about which having been torn down, we gain some idea of the construction of the pyramid. In this manner the passage has lost somewhat of its length. The passage itself is 3 feet 11 inches high, and 3 feet 6 inches wide, and is lined with fine limestones at an angle of 26° 41'. At a distance of 63 feet 3 inches from the beginning of the roof of the present entrance, a second passage commences from this, taking an ascending direction. The entrance of this new passage is obstructed by great blocks of granite which entirely fill it, and have been passed by means of an excavation around them. We thus enter the ascending passage, which is of the same breadth and height as the former, and inclines at an angle of 26° 18'. The stones which line its roof and sides are very rough, and it has evidently been left unfinished.

After ascending this passage for a distance of 109 feet 7 inches, we reach the Grand Passage, which, from its greater dimensions, presents a comparatively imposing appearance. It ascends at the same angle as the last, whose horizontal passage runs beneath it to a chamber to be subsequently mentioned. Just within the Grand Passage is the mouth of the Well, an irregular pit, partly excavated in the rock, leading to the lower portion of the first passage. Its object was probably to afford an exit to those men who had been engaged in closing the ascending passage. The Grand Passage is 6 feet 10 inches in width at its base, 28 feet high, and 156 feet long. The blocks which compose its sides gradually approach, every course above the second projecting a little; at the mouth of the passage a horizontal one begins, of much smaller but unequal dimensions, and 22 feet 1 inch in length, leading to the Grand Chamber, commonly called the King's Chamber, which it enters at the eastern end of its north side. This chamber, which is the principal sepulchral chamber (unless, indeed, there be an undiscovered one of greater importance), is lined with red granite, and measures in length 34 feet 5 inches, in width 17 feet 1 inch, and in height 19 feet 1 inch. It is altogether plain, and contains only a sarcophagus of red granite, which is equally undecorated. Above this chamber are five small ones, which may be called entrenches, evidently designed to lighten the pressure of the superincumbent masonry, particularly as the uppermost of them has a pointed roof. Four of these were discovered by the late General Howard Vyse, who found in them quarry-marks, bearing, in two varieties, the name of Khufu, the royal builder of the pyramid. These chambers are reached with difficulty, and chiefly by forced passage. The horizontal passage beneath the Grand Passage must now be described. This is but 5 feet 10 inches high, and

3 See Sir John Herschel's Observations on the Entrance Passages in the Pyramids of Gizeh, in Vyse's Pyramids of Gizeh, vol. ii. pp. 107-109. The different angles of the entrance passages of other pyramids, and the circumstance that they were always closed at the completion of the buildings, show that the king's remains were put, at a supposed date of his erection, to a Drascoma, which was then the pole-star, and is not to be regarded as more than accidental. However, as above mentioned, the pyramids face the cardinal points.
3 feet 5½ inches wide, for the first 92 feet of its length, and then we descend a step and find the passage to be 5 feet 8 inches high for 17 feet 11 inches farther, until we enter the "Queen's Chamber," as it is usually called, at the eastern corner of its north side. This chamber is 18 feet 9 inches long, and 17 feet broad, and its extreme height is 20 feet 3 inches. It has a pointed roof, of great blocks of stone, inclined upwards and meeting in the middle. Within it is the entrance of a forced passage. The remainder of the first passage, beyond where the first ascending passage leads to the most interesting parts of the structure, is still to be noticed. It continues below the forced entrance to the ascending passage for a distance of 236 feet 10 inches, being cut through the rock on which the pyramid is built. For this space its inclination and proportions do not change, but it then becomes horizontal for 27 feet, terminating at the entrance of an excavated chamber 46 feet in length, and 27 feet 1 inch in breadth, but of irregular and inconsiderable height. There is no doubt that this chamber was left unfinished at the closing of the pyramid. Beyond it the passage continues, opposite to where it entered the chamber, and extends horizontally 52 feet 9 inches into the rock in the same direction.

The Second Pyramid, which bore the name of "the Great," is what the tomb of Menkaura (Dynasty IV.), stands at a short distance to the south-west of the Great Pyramid, which does not very much exceed it in magnitude, though far superior in its construction. It has a base of 690 feet 9 inches square, and 447 feet 6 inches in height, being more steep than its larger neighbour. A great part of its casing having been preserved, extending about a fourth of the distance from the summit, the ascent is very difficult, especially as when one has climbed on to the casing portion he can see nothing of the lower part of the building, and thus feels as if upon a pyramid in the air. There are two entrances, both in the north side, from which, and other peculiarities, it is possible that the building was originally much smaller than now, and that, after its first completion, it was enlarged, and a new entrance and sepulchral chamber added.

The Third Pyramid, "the Superior," the tomb of Menkaure, or Mycerinus, is almost in a line with the other two, and of much smaller dimensions, being only 203 feet in height, and 354 feet 6 inches square at the base. It is constructed beautifully, and in a costly manner, and in these respects is unequaled, if equalled, by any other pyramid. The exterior was anciently cased altogether, or covered with a granite, but this has been generally torn off. General Vyse opened it, and found that it had been previously ransacked. In it he discovered a very beautiful sarcophagus (which was unfortunately lost at sea on its way to England), as well as part of a mummy-case, bearing the name of King Menkaure, and a mummy, not certainly the king's, both of which are now in the British Museum. This confirms the statement of Herodotus that it was the tomb of Mycerinus. Manetho says that it was built by Queen Nitocris (Dynasty VI.). This apparent incongruity is explained, as Bunsen remarks ("Egypt's Place, ii. 165, sq., 210, sq.), by the construction of the pyramid, which has two principal chambers, and was evidently enlarged after its first completion, so that we may reasonably suppose that it is the sepulchre of both Menkaure and Queen Nitocris.

Near the three large pyramids are six smaller ones; three of these are near the east side of the Great Pyramid, and three on the south side of the Third Pyramid. They are probably the tombs of near relations of the kings who founded the great pyramids. The space around the pyramids is occupied by very numerous tombs, some built of stone, others excavated in the sides of the rock on which the pyramids stand, while others are simply pits with sepulchral chambers leading from them. The most interesting of these occupy a square bounded on the east by the Great Pyramid and on the south by the Second, and are mostly the sepulchres of the subjects of Khufu and other kings of Dynasties IV. and V. These tombs, which are of inconsiderable dimensions in comparison with the others and elsewhere, are all built of stone, and have inclined walls, so as to resemble truncated pyramids. They usually contain a chapel, or more rarely chapels, the walls of which are decorated with most remarkable painted sculptures, portraying the everyday life of the Egyptians at that remote age, with short inscriptions of an explanatory character. The absence of representations of the gods and subjects clearly connected with religion is noteworthy. Other similar tombs stand to the east and south of the Great Pyramid; and in the former direction are the principal sepulchral grooves hewn in the side of the elevated rocky tract on which the pyramids stand. Some of these excavations bear similar representations to those of the other tombs already mentioned. To the east of the Second Pyramid is the Great Sphinx, called in Egyptian "cvsnu," emblem of Hor-em-akhu, "Horus in the horizon," one of the most characteristic monuments of the Sphinx, of an earlier date than the Great Pyramid. It is a recumbent androphophus, or man-headed lion, 188 feet 5½ inches in length, hewn out of a natural eminence in the solid rock, some defects of which are supplied by a partial stone casing, the legs being likewise added. Steps lead down to its front, where are a sanctuary and tablets, but these are covered by the sand, which, after the hollow has been cleared, speedily fills it again. Not far to the westward of the Sphinx is the remarkable enclosure known as Campbell's Tomb, discovered by General Vyse, chiefly consisting of a large pit surrounded by a trench. The causeway leading to the Great Pyramid and to the Third, the former of which greatly excited the admiration of Herodotus, are well worthy of a careful examination. The only pyramid which stands to the north of this group is that of Aboo-Ruweysh, which is in so ruined a condition as scarcely to deserve a visit. It lies about five miles to the north of the Great Pyramid.

Southward of the Pyramids of El-Geezeh, the first objects of interest are those forming the similar group of Aboo-Seer, of much smaller dimensions, the largest being about the size of the Third Pyramid. They are on the elevated edge of the Libyan chain, about seven miles from the Third Pyramid, and are four in number, three being large, and the fourth very small. The Northern Pyramid of Aboo-Seer appears to have been the tomb of Saha of Dynasty V., and the Middle Pyramid is the tomb of Ra-nuer of the same line.

About two miles farther in the same direction are the Pyramids of Sakkarah, the greatest and most remarkable of which is called the Pyramid of Sibis. The tract around them appears from the number of the tombs to have been the principal burial-place of Memphis, to which it is near. The Pyramid of Sibis has a height of 196 feet 6 inches, and its base formerly measured on the north and south sides 351 feet 2 inches, and on the east and west 293 feet 11 inches. Within it are numerous passages and a gallery, which must, for the most part, have been made subsequently to the completion of the structure. In the centre is a very lofty and narrow chamber, and near it a small one, which was lined with blue tiles. In the latter was an inscription containing the title of the bulls Aps. Under the old monarchy those sacred animals were here entombed. It is thought that this pyramid was constructed by Uenephes of Dynasty I. If Manetho be correct in assigning the introduction of the worship of Aps to a later king, this
pyramid, if of Unesheps, was originally a royal sepulchre. In the tract between the Pyramids of Sakkarah and Abou-Seer are the remains of the Sarapeum, and the burnuplase of the bulls Apis, both discovered by M. Mariette. They are inclosed by a great wall, having been connected, for the Sarapeum was the temple of the defunct Apis. The tombs are in subterranean galleries or in separate excavations which contain many sarcophagi, in which the bulls were en­tombed. Not the least important result of this discovery is the certainty that Sarapus was a form of Osiris, and that his name was Heisiri-hapi, or Osiris-Apis (Brugsch, **Reiseberichte aus Aegypten**, 27, 305), as Sir Gardner Wilkinson had long previously suggested (**Matema Hieroglyphica**, 21, and **Vocab.** M. 8, 9). The other pyramids are of comparatively little interest. There are also some curious private tombs, among which may be particularized a large grotto excavated in the face of the rock overlooking the valley, which is remarkable for being vaulted on the principle of the true arch, but without a key-stone. It is of the time of Memnonius I. of Dynasty XXVI., being, as Sir Gardner Wilkinson remarks, one of the two earliest known examples of the arch in stone, though, as he adds, there are brick arches at Thebes of the time of Amenophis I. of Dynasty XVIII. (**Modern Egypt and Thebes**, i. 500–509).

The site of Memphis is marked by mounds in the cultivated tract to the east of the Pyramids of Sakkarah, and near the village of Most-Selahenouch. Of the great temple of Ptah, its tutelary divinity, there are no remains above ground, except a few blocks of stone and some broken statues, one of which is a fine colossal of Ramesses II., which may probably stood in ancient times before one of the principal entrances of the temple. It is of white chert, and beautifully executed, representing the king in a standing posture. It has fallen to the ground, and has lost part of its legs; nevertheless it has suffered considerable damage elsewhere, so as to be still one of the finest specimens of Egyptian art. The original height was more than 40 feet. This colossal is the property of the British nation, but no steps have been taken to remove it to this country. As Sir Gardner Wilkinson remarks, "when the Turks have burnt it for lime, it will be regretted" (**Modern Egypt and Thebes**, i. 373). The site of Memphis being in the cultivated tract, and near the modern capitals of Egypt, its monuments have alike suffered from the destructive power of nature, and from the barbarism of those who have used them as quarries or defended them from motives of fanaticism. The Pyramids have not escaped man's violence, but their vastness has generally defied his attacks.

At a distance of about five miles to the south of the Pyramid of Sekhem-Re is the northernmost of the Pyramids of Dahshoor, an interesting group, of the history of which not a certain is known. To their north is a vast truncated pyramid, the sepulchre of Unas, last king of Dynasty V., anciently called "the Most Beautiful Place," now Mastabat Farasun, or "Pharaoh's Seat." Two of the Pyramids of Dahshoor are of stone, and three of crude brick. The former exceed in size all the other pyramids except the Funis and Second of El-Geesheh, and have remarkable chambers within them. The Northern Stone Pyramid has a base of 700 feet, and a height of 326 feet 6 inches, and has lost somewhat of its size, having originally measured 719 feet 6 inches, and 343 feet 7 inches. Some of the eastern face, leading to three chambers of similar construction to the Grand Passage in the Great Pyramid. The Southern Stone Pyramid is distinguished by the peculiarity of its form and by having two entrances, one in the eastern face and the other in the northern. The lower portion has an angle of 54° 14' 46"., but the inclination then changes to 42° 59' 26". It has been supposed that it was suddenly completed, having been originally planned to be much loftier, but the method in which the pyramids were built renders this unlikely, and it seems rather to have been given this form to gratify a whim of the founder, as externally the entrances in different faces afford another peculiarity. Its base is 615 feet 8 inches, and its height 319 feet 6 inches. At its southern side is a small brick pyramid. The Northern and Southern Brick Pyramids of Dahshoor are to the east of those already described. They are now in a very ruined state, being merely mounds of crude brick; one of them is probably the Pyramid of Asychis mentioned by Herodotus.

Among the earlier explorers of the necropoleis of Memphis was Belonzi, by whom the Second Pyramid was opened. General Howard Vyse first undertook a complete examination of the series of pyramids, and having secured the assistance of Mr Perring, carried out this project with well-merited success. Professor Lepsius, the head of the Prussinan expedition, opened many tombs in the Memphite necropolis, and has published in his magnificent work (**Denkmaler aus Aegypten und Aethiopen**) the most interesting sculptures which they contain. M. Mariette, aided by the French Government, discovered the Sarapeum and the tombs of the bulls Apis, and has since continued his researches under the authority of the khedive.

The voyage up the Nile from Cairo may now be described. Not far south of Masr El-Attekahl, the mountain and desert approach very near the river on that side, and soon after the wide opening of a valley is seen. Beyond it is a bold promontory of the eastern range, which first gradually recedes and then becomes parallel with the river for some distance, leaving but a narrow strip of cultivated land. Behind the village of Turah, the ancient Thebes, are the quarries named after it, and a little farther to the south are those of El-Massaieh. These quarries are great excavated chambers and passages, which are entered by large square apertures in the steep face of the mountain. Hence were taken the finer blocks of limestone employed in the construction of the Pyramids of El-Geesheh. Tablets in both quarries record the quarrying executed under different sovereigns. South of the quarries the character of the eastern bank continues unchanged, and presents no remarkable object until we reach the promontory of the Sheykh Abou-Noor, which will be subsequently mentioned. The western bank, on the contrary, is broad and fertile, abounding in villages, and above its palm-groves rise in the distance the massive forms of the long series of pyramids. Considerably beyond those of Dahshoor, which may be considered the most southern in the Memphite necropolis, are the two Pyramids of El-Metaweeyeh, which are too small to be seen from the river, and yet farther the solitary Pyramid of Meydoon, commonly called the False Pyramid.

Dr Brugsch thinks it very probable that it was the tomb of Semannur, last king of Dynasty III. It is a structure of great size, having a base of about 400 feet, and a height of about 310 feet. In consequence of blocks having been pulled off its sides for building purposes, it has the appearance of being built in two degrees, the lower of which is much greater than the upper, while the fallen stones around its base make it seem as if raised upon an eminence to increase its apparent size, and hence its name. The entrance has not been discovered. Its position, rising alone above the rich valley and desert beyond, without any object by which to measure its size, render this pyramid, especially when seen from some distance across a broad strip of the river to the north, a very striking object. There is nothing else worthy of a visit on the western bank until...
we reach the town of Bence-Suéf, about seventy miles by the course of the river from Cairo.

Bence-Suéf is a busy town, being the port of the Faiyoom. A road leads hence to that province, in a north-westerly direction. After crossing the great canal called the Baher-Youssef, we pass through the opening in the Libyan range which leads to the Faiyoom, leaving on our right the ruined brick Pyramid of El-Łahoon, so called from an adjacent village.

The Faiyoom, including its lake, is a pear-shaped tract (its narrowest part being to the west), extending into the desert, and measuring in its greatest length about thirty miles, and in its greatest breadth about twenty. The part now cultivated is more than two-thirds of this extent from the east. At the north-western extremity is the great lake of El-Karn, which is long and narrow, and fills the northern portion of the valley. A branch of the Baher-Youssef flows through the opening leading to the Faiyoom. This canal soon spreads into many streams, two of which, after joining into a single course, carry off the superabundant waters of the inundation into the lake of El-Karn, while they contribute with the others to irrigate the cultivable tracts.

The site of the famous Labyrinth first claims our notice after leaving the Faiyoom. Its position may be known by a ruined crude brick pyramid, that of Hawaráh, which is spoken of by both Herodotus and Strabo, and may be called the Pyramid of the Labyrinth. The remains of the Labyrinth itself, which had been previously known, were first carefully examined by the Prussian expedition headed by Professor Lepsius, in 1843. The structure was so ruined, however, that the results were not as decisive as might have been hoped. Yet the plan was to some extent made out, and the building shown to have contained a great number of very small chambers, as ancient writers had said; and the discovery of royal names of Dynasty XII., particularly of Aménemhat III., to whom Manetho ascribes the founding of the Labyrinth, leaves little doubt that this was the Morís who built the Labyrinth, according to the classic writers. The use of this building has not been distinctly ascertained. Manetho indeed makes it to have been the founder's tomb, but it is most probable that he was buried in the pyramid, which, however, the Egyptian historian may have regarded as part of the Labyrinth, as it is evidently connected with that structure.

Not far beyond the site of the Labyrinth is the capital of the province, usually called “El-Medémén,” or “El-City,” and “Medéenat-el-Faiyoom,” “the City” or “Capital of the Faiyoom,” close to the mounds of the ancient Arunoe, or Crocodilopolis. It is a small but flourishing town. The only monuments of antiquity in its neighbourhood are the remains of Beyhoom somewhat to the north, and the great broken tablets at Begeeg, at a smaller distance to the south. The former are two structures supposed by some to be pyramids, and the latter, which is a record of the time of Usurteen I., is usually called an obelisk, but it must rather be regarded as a very tall and narrow stele or tablet, upwards of 40 feet in height.

In this part of the Faiyoom, to the north of El-Medémén, may be traced the remains of that remarkable hydraulic work the Lake Morís. M. Linant, a French engineer, was the first to determine the position and character of this famous work of antiquity; and the results of his investigations are in accordance with the observations of some who had previously noticed the subject in published works (“Mémoire sur le Lacs Morís,” Soc Ég., 1843). The object of the Lake Morís was to regulate the irrigation of the Faiyoom, anciently the Crocodilopolite Nome, and afterwards the Arinóite; and it was valuable on account of its fisheries. It seems rather to have deserved the name of a very large reservoir than that of a lake. Notwithstanding the drying up of the Lake Morís, the Faiyoom is still an important and fertile province. It produces very large quantities of grapes; and the fields of roses, cultivated for the sake of rose-water, present a remarkable appearance.

The great Lake of El-Karn is perhaps the most interesting object in this part of Egypt. Its name, Birket-el-Karn, signifies “The Lake of the Horn,” or “Projection,” by which an island is intended, and not its general form, as has been supposed. It is, according to Sir Gardner Wilkinson, about 35 miles long and about 7 broad at its widest part and is not deep, as far as has been ascertained. The water is brackish and unwholesome, though derived from the Nile, which has at all seasons a much higher level. It is bounded on the south by tracts in a state of cultivation, but deserted for want of labourers, though anciently cultivated, and on the north by the Libyan desert, above which rises a bold range of mountains; and it has a strange and picturesque wildness. Its northern shore was anciently cultivated, at least in part, but is now entirely waste. Near the lake are several sites of ancient monuments.

The Egyptian historian may have regarded as part of the Labyrinth, as it is evidently connected with that structure.

The water flows through the opening leading to the Faiyoom, and the temple called Kasr-Károm distinguishes the most important of these. That temple, however, being devoid of sculpture, and does not possess the Roman period, could not attract attention except in a region barren of monuments.

After this cursory view of the Faiyoom we may return to the Nile and continue our southward course.

Not far south of Bence-Suéf the eastern chain is washed by the river at the picturesque promontory of the Shékh Aboo-Noor, whose tomb stands on its summit. From this point as far as the town of Manfaloot the mountains on the east are close to the Nile, leaving a narrow space of cultivable land, on the northern portion of which are several sites of ancient towns, of which the most remarkable are the sepulchral grottoes of Benee-Hasan, which are inferior to those of the Crocdillopite Nome, and shared the same fate at his hands.

These are of the age of Dynasties IV. and VI., but they have sustained so much damage in modern times that they do not repay a visit, except from one who is a student of hieroglyphics. A governor of El-Minyéh, an ignorant Turk, used these ancient tombs as quarries; and had it not been for the interference of Mr Harris of Alexandria, the more important grottoes of Benee-Hasan would have shared the same fate at his hands.

The first noteworthy objects above El-Minyéh are the sepulchral grottoes of Gebel-ès-Tyre, the most remarkable of the latter being at a site called El-Kom-ès-Ahmar, or “the Red Mound.” These are of the age of Dynasties IV. and VI., but they have sustained so much damage in modern times that they do not repay a visit, except from one who is a student of hieroglyphics. A governor of El-Minyéh, an ignorant Turk, used these ancient tombs as quarries; and had it not been for the interference of Mr Harris of Alexandria, the more important grottoes of Benee-Hasan would have shared the same fate at his hands.

cultivable land. The grottoes are almost in a line near the summit of the mountain, and at no great height above the river. The two northernmost are remarkable for having poricoes, each supported by two polygonal columns of an order which is believed to be the prototype of the Dore. Most of the grottoes are adorned with sculptures and paintings, which portray with eminent truthfulness and character the manners of the Egyptians of the remote period at which they were executed, for they are tombs of monarchs and other governors of Dynasty XII. They generally consist of a chapel of large dimensions, having sometimes a portico before it, and a niche with seated figures of the chief persons buried in the tomb at the extremity, and have pits leading to sepulchral chambers. The principal apartment is sometimes supported by pillars cut out of the rock, and vaulted. Its walls bear representations of the diversions of the occupant during his lifetime, and of his varied occupations, in scenes depicting hunting, fishing, games, feasts, the processes of agriculture, and the like. The figures of beasts and birds, more especially the latter, are characterized by a remarkable fidelity and beauty, and there can be no doubt that Egyptian art had attained a greater excellence at this time than it possessed under Dynasty IV. A little to the south of these grottoes, in a ravine, is the Speos Artemidu, a small rock temple of Sekhert or Pakh, the Egyptian Diana, and some sepulchres of little interest.

A few miles to the south of the Speos Artemidu are two sites, one on either side of the river, which were marked, in the present century, by most important monuments, which have since been destroyed by the Turks. That on the western side, near the large village of El-Ashmooney, the ancient Hermopolis Magna, was part of a magnificent portico, bearing the names of Philip Ardeus, Alexander Egnus, and Polymy L., all that stood of the temple of Thoth, and on the opposite side of the river were considerable remains of the edifices of the town of Antinoopolis founded by Hadrian. While we regret the destruction of such interesting records, we must not charge either the Turks or the native Egyptians with all the mischief of this kind which is perpetrated, and our sorrow is increased by the reflection that to European travellers, principally Englishmen and Americans, must be assigned no small share in the destruction or mutilation of the monuments, which in the case of educated men is nothing less than a crime.

A short distance south of Antinoopolis is the town of Melawa, on the western bank, and a little farther, on the other side of the river, the promontory called Gebel-esh-Sheykh Sa'eed, which is honeycombed with grottoes, some of which are shown by their sculptures to be very ancient, but are so ill preserved as to require but a short examination. A little beyond, however, in the district of Tell-El-Amarnah, or the Mound of El-Amarnah, a small fertile tract where the eastern mountains recede, noted, like Benc-Hassan, for the turbulent and thievish propensities of its inhabitants, are most curious remains of a very ancient town. It was the capital of Khn-n-aten, the sun-worshipper of Dynasty XVIII., and was not destroyed by Horus, and not subsequently rebuilt. In the mountain behind it are very interesting sepulchral grottoes, in which were buried the courtiers of this king, and from them we obtain much information respecting his religion, a very pure form of sun-worship. The representations are chiefly of the king, his queen, and their children, distributing presents to the soldiers and others, of acts of worship to the sun, and of the temple of the sun as well as gardens and villas.

A little farther up the river, on the north side of the Nile, a little to the south of Tell-el-Amarnah, is the small town of Dercot-esh-Sherreef, supposed to be on the site of the Thebaica Phylace, which guarded the northern boundary of the Thebaa. About 20 miles to the south is the town of Manfalout, on the same side of the river, which has a decayed appearance from the manner in which the stream has encroached upon and washed away part of it. Opposite to Manfalout in the eastern range are extensive crocodile-mummy catacombs.
of Abydos as a reputed burial-place of Osiris rendered this a favourite necropolis of the ancient Egyptians from very early times, particularly under Dynasty XII.

At a distance of more than 40 miles from Abydos, but in nearly the same latitude, is the village of Dendarah, on the left, near the southern bank of the Nile. Before reaching it we pass the small town of Farshout at the mouth of the great canal called the Bahr-Yosuf, and the large village of Hoo, marking the site of Dendera Farra Opposite the latter place are some sculptured grottoes in the eastern chain, called those of Kuer-ese-Sayad, which is believed to occupy the position of Chaotkosoecon. They contain names of kings of Dynasty VI, but the representations which occupy their walls are not of unusual interest. At Denderah is the first well-preserved and unencumbered temple that is seen in a voyage up the Nile, that of Abydos, the Egyptian Venus, who presided over the town of Tentyra, or Tryenti, the capital of the Tentyrites. It stands on the mounds of the town about a mile and a half from the Nile. From it we gain a good idea of Egyptian religious architecture under the Greek and Roman dominations.

The temple is surrounded by a great wall of crude brick, entered by a stone portal adorned with sculptures representing the emperors Domitian and Trajan, engaged in acts of worship before several divinities. The portico to which it leads is about 355 feet in width, and is one of the richest and most beautiful structures of the kind. It is supported by twenty-four columns, four deep, nearly 50 feet in height, and having a diameter of somewhat more than 7 feet at the thickest part. The capitals have a full face of Athor sculptured on each of their four sides, and above these a kind of shrine. The three columns on each side of the entrance are connected by an intercolumniation. The portico, like the rest of the temple, is of higher merit as regards its architecture than its sculpture, for the latter art had declined under the Greek and Roman rule to a much greater degree than the former. The sculptures are of the same kind as on the portal, representing offerings made by some of the earlier Caesars; and on the ceiling are various mystical subjects, probably of an astronomical import, and the famous Zodiac from which an extravagant idea of the antiquity of the temple was deduced before hieroglyphic decipherment. The greater part of the back wall of the portico was the front of the temple before this portion was added. The inner part consists of three considerable chambers, an isolated sanctuary, and numerous small apartments. The first of these is a hall, supported by a double row of columns, three on each side, of a rather heavy form, for they have, beneath the capital formed of the block with the faces of Athor and the shrine, another capital of a cup shape. The hall is entered by a doorway in the middle of the back wall of the portico, and passing through it we reach a second and third chamber of the same breadth but shorter, and then the sanctuary. This chamber is much narrower, and is isolated by a passage running round it. On each side of the chambers and passage are many small apartments, two passages to the exterior, and two staircases, and there are singular inclined passages in the walls, two of which are entered from the sides of the portico. The whole interior is covered with sculptures and inscriptions of a religious character, stating in a systematic manner the use of each chamber in the temple-worship. The royal names have not always been filled in, the rings remaining vacant; but when they have been sculptured, they are generally those of the last Caesars, and Ptolemy Caesar, his son by Julia Caesar. On the roof of the temple to which the staircases lead, there is a sort of chapel and some small chambers, one of which is very interesting, because its sculptures relate to the myth of Osiris. The exterior of the temple is as completely covered with sculptures as the interior. Among the figures represented here are those of Cleopatra and Ptolemy Caesar; but they cannot be supposed to convey any resemblance, since they belong not alone to a conventional art, but almost to its lowest period. There are two smaller temples near the great temple of Athor, one of Ias, and the other of the kind called a Typhonomum. Both are of the Roman time. See admirable account of the temple in Marrot's Monument de l'Upper Egypt.

On the opposite side of the Nile, a little above Dendara, is the town of Kus, between which and Arbusa so little traffic is carried on by the route through the desert to Kusey on the Red Sea. The best of the porous clay bottles which are used throughout Egypt are manufactured here, and the great water-jars, called "bellases," which the women carry, are made at the large village of Bellas, a few miles higher on the western bank. Opposite to Bellas is the village called Kus or Kift, marking the site of the important town of Copos, which was the emporium on the Nile of the Araban and Indian trade under the Ptolemies, and, somewhat to the south, is the considerable town of Koss, the ancient Apollinopis Farva, which succeeded to the trade of Copos, under the Mutasius, until Knill supplanted it. On the western edge of the small town of Nakadeh, which the people call Nagadeh, where are Roman Catholic and Coptic convents. A short distance beyond Nakadeh are the northernmost of the remains of Thebes.

The monuments of Thebes do not present from afar the imposing appearance of the Pyramids of Memphis. Placed for the most part at a distance from the Nile, as well as from one another, and having on the western side the picturesque mountain, they are the most suitable object for inland navigation. The monuments of Thebes do not present from afar the imposing appearance of the Pyramids of Memphis. Placed for the most part at a distance from the Nile, as well as from one another, and having on the western side the picturesque mountain, they are the most suitable object for inland navigation.
city was on the eastern bank, where is the great temple, or rather collection of temples, called after El-Karnak, a modern village near by. The temple of El-Karnak is about half a mile from the river, in the cultivable land. More than a mile to the south-west is the temple of El-Uksur, on the bank of the Nile. On the western bank was the suburb called the name Monanmah. The temple near the northermost of the temples on this side, the Setheem, almost reaches the river, near the edge of the desert, which has been sculptured over another subject, of those of several places in the eastern approaches to the river, being the greatest of the temple, and several smaller structures, surrounding it. The grand entrance is through a propylon more than 360 feet wide, for this is its measure above the rubbish which is piled up around it. It was never sculptured, nor was its surface smoothed. It presents, therefore, a rude appearance, and is much ruined. A great part of the left or northern wing having been demolished. The court of which the propylon forms the front measures 322 feet in width and 375 in length, having on each side a gallery with a single row of columns, and a double colonnade, of which one column alone stands, formed an avenue from its entrance to that of the hypostyle hall beyond. On the right side a temple of older date interrupts the side gallery, extending 50 feet into the court. Its front is formed by a propylon, about 90 feet wide, on each wing of which tremendous sculptures are of the reign of Ramses III, but the names of later sovereigns occur. On the other side of the great court is a small structure which may be a chapel, or three chapels. The most interesting sculptures in this part of the group of temples are outside the eastern portion of the south wall of the great court, for here is the famous list of countries and towns subdued by Sheshonk I, or Shishak, the head of Dynasty XXII. Among the names is that thought to be the kingdom of Judah, and those of several places in the dominions of Rehoboam and Jeroboam I. At the end of the court is a fine portal, the wings of which are much ruined. This is the entrance to the great hypostyle hall, the most magnificent work of its class in Egypt. Its length is 170 feet, and its width 329 feet, supported by 134 columns, the loftiest of which are nearly 70 feet in height, and about 12 inches in diameter, and the rest more than 40 feet in height, and about 5 feet in diameter. The great columns, in a number, form an avenue through the midst of the court from the entrance, and the others are arranged in rows very near together on each side. There is a transverse avenue made by two rows of the smaller columns being placed farther apart than the
rest. This great hall is therefore crowded with columns, and the effect is surprisingly grand. The spectator, being generally unable to see beyond the columns which are immediately around him, perceives the vast dimensions which, if viewed from a distance, might lose their effect. The forest of columns seems interminable in whatever direction he looks, producing a result unsurpassed in any other Egyptian temple. The partial ruin of its stone roof, and of some of the columns, love stone in Egypt, the more picturesque, and makes us wonder at the forces which must have been expended in attempting to demolish it. This grand hall was built by Setee I., Dynasty XIX., and sculptured partly in his reign and partly in that of his son and successor Ramses II., who has sometimes effaced his father's name to substitute his own. It commemorates, not in its grandeur alone, but also by its sculptures, the magnificence and power of these two great Pharaohs. The sculptures of the interior of the walls represent these kings making offerings to the gods, and the like subjects occupy the columns. Far more interesting are those which adorn the exterior of the walls, and record the achievements of the same kings, those of Setee I. being on the north wall, and those of Ramses II. on the south. The former are of much greater interest than the latter, as far as we can judge, and in this respect in no more in Egypt than elsewhere. The scenes on the north wall are arranged in three compartments, of which the upper one has been nearly destroyed. In these scenes the king is represented of a gigantic size, charging in his chariot, and putting to rout his enemies, capturing their strongholds, and returning home in triumph. The chief nations are the Ketesh or Hittites; the Kutesh (Luten), at this time a great nation of Syria; the Shasu, or Arabs; the Khatts, Syrians, or Syrians; and Remenen, Armenia. Among the captured places is Kekekh, in those days the most important stronghold between Egypt and Mesopotamia. There is also a long list of countries, cities, and tribes, conquered or ruled by the king, among which we find Naharain, that is Aram-naharaim, or Mesopotamia, Keesh, Kush, or Ethiopia, &c. The battle-scenes of Ramses II. on the south wall do not, as far as they are seen, equal those in interest. Here also is a list of the king's conquests and possessions, and on the west side of a wall which joins this one at right angles, forming the side of a court of the southern approach to the temple, is a representation of the capture of Ascalon or Askelon, and an inscription recording the treaty between Ramses II. and the Ketesh, concluded in the twenty-first year of his reign. The back of the hypostyle hall is formed by a ruined propylon bearing the name of Amenophis III., and then at a distance of about 50 feet is another propylon, entirely ruined. In the space between these propylas, which was a court, stands a beautiful obelisk of red granite, upwards of 70 feet high, raised by Thothmes I. The fragments of its fellow, which was more to the north, slew the ground. Behind the second of these propylas is another granite obelisk, 108 feet high, and according to M. Mariette the loftiest known (Monuments of Upper Egypt, 170). This great obelisk of El-Karnak is a monument of Queen Hatshepsut of Dynasty XVIII., and an inscription on its pedestal records the period which elapsed (nineteen months) from the time that it was begun to be cut in the quarry until its completion in the queen's sixteenth year. The fellow of the great obelisk, which stood to the south of it, has been broken, and its fragments occupy its place. Beyond the great obelisk is the chief sanctuary, a structure almost entirely of granite, divided into two apartments, which was built under Philip Aridaus, in the place, no doubt, of one destroyed by Cambyses or Ochus. The space between the hypostyle hall and this sanctuary is extremely ruined, the huge stones being piled up in heaps as though an earthquake had overthrown the temple. But this destruction was probably due to human violence. Behind the sanctuary are fragments of a very ancient part of the temple, bearing the name of Amenophis I. and Dynasty XII. Considerably farther is a large oblate building of the time of Thothmes III., which affords a remarkable example of architectural caprice, its columns having inverted shafts and capitals, and its cornices being likewise inverted. Behind this and a stone wall are ruined chambers, and far beyond, directly behind the centre of the great temple, in the crude brick wall of inclosure, is a handsome portal, never finished, bearing the name of Nectaneboes II.

The southern approach to the temple of El-Karnak from that of El-Ukns is, as before mentioned, by a ruined avenue of sphynxes, which ends near the great structure, and two other avenues begin. The westernmost of these, which is of colossal rams, conducts to a temple situate not far to the south-west of the first court of the great temple: we approach it through a stately portal bearing in its inscriptions the name of Ptolemy Euergetes I. The front of the temple, before which was another avenue of rams, is a propylon, which is almost unjured. Behind it is a court having a double row of columns on each side, and at the end, and again behind this is a hall supported by eight columns, and many and small chambers. This temple was dedicated to Khons, the third member of the Theban trund. It was begun under Dynasty XX., and continued by the high-priest kings. A small edifice having sculptures of the time of the Greek and Roman rule stands on the west of the court of this temple.

The avenue of sphynxes which branches off at the same place as the avenue of rams leading to the temple of Khons takes an easterly direction and ends where another begins at right angles to it, which connects the southern courts leading to the great temple with a separate inclosure. The latter contains a lake which has the shape of a horsehoe, and the remains of the temple of Mut. At the northern extremity of the avenue, which is of cricosphynxes, is a propylon forming the front of a large court ending in a second propylon, which, like the other, is much ruined. Beyond this, but not in exactly the same direction, after a vacant space, the approach continues through two or smaller propylae, the second of which is nearly destroyed. Each fronts a court, and at the end of the second of these courts was the great side entrance to the temple. The first and second propylae were, like the cricosphynxes, monuments of King Har-em-heb, or Horus, of Dynasty XVIII., and were partly built of materials of a temple or palace of the sun-worshipping kings whom he overthrew. The third propylon is more ancient, for it bears the name of Thothmes III. and Amenophis II., as well as of subsequent kings; the age of the fourth is not certain; the name of Ramses II. occurs here, but it may have been founded before his time. There is an inclosure in the angle formed eastward by the third and fourth propylae with the great temple, which contains a sacred lake.

Adjoining the great crude-brick wall of inclosure at its north-eastern portion is another containing the ruins of an important temple. The chief approach is through a stately portal of the Ptolemaic period, in the crude-brick wall. The temple to which it conducted was very beautiful and costly, as we can judge from its remains, which show with how much violence it was destroyed. It seems to have been founded under Dynasty XVIII. There are two small temples or chapels, one of the time of Achoris and the other of that of Nectaneboes I. and II., in the same inclosure. Another crude-brick inclosure of small dimensions, near the south-east corner of that of the great temple, contains some unimportant remains of a small edifice.

This brief description will convey some idea of the dimensions of the temple of Amen-ra at Thebes, with its...
appended; but no one who has not seen that wonderful assemblage of ruins can picture to himself the massiveness of its castle-like propylies, the grandeur of its hall of columns, the beauty of its great obelisk, and the sublimity of its heaped-up ruins. Of the city of Thebes there are scarcely any remains. Doubtless its edifices were of perishable materials.

Beginning our examination of the monuments of the western bank, where was the great suburb of the Memnonia, from the northward, the first object of interest is the Setheum, a small temple of Setee I., which the natives call Kaar-Er-Rubeyk, at the ruined village of El-Kurnehe. A portico, originally supported by ten columns, of which two have fallen, extends along the whole front of the building. Three entrances lead into the interior of the temple: the middle one of these is the door of a hall having twelve columns. From this apartment we pass into several small chambers, which are of little interest, like the ruined chambers which we enter from the northern door. The southern door is the entrance of a separate part of the edifice, which contains a small hall supported by two columns, and three chambers behind it, the middle one of which was a sanctuary or chapel, devoted, as its sculptures show, to the worship of Ramses I., the father of Setee I. The inscriptions of the temple tell us that it was dedicated to Ammon by its founder Setee I., and continued by his son Ramses II., and his grandson Menephtah. It was the funerary chapel of the tombs of Ramses I. and Setee I.

The great temple of Ramses II., which may be called the Ramesenm of El-Kurneh, but is commonly though incorrectly known as the Memnonium, is situated at a distance of about a mile to the westward of the Setheum, and is like it on the edge of the desert, which here is much farther from the Nile. Notwithstanding that its condition is much more ruined than that of other edifices of Thebes, the beautiful architecture of what remains, and the historical interest of its spirited sculptures, render it altogether second alone in its attractions to the great pile of El-Karnak. A propylon, 225 feet in width, of which a great part has been thrown down, forms the front of the edifice. Through its portal we enter a spacious court 180 feet wide and 142 long. It had originally a double colonnade on either side, every column of which has been destroyed, while the side walls have been entirely demolished and the end wall partially. On the back of the propylies are sculptured a battle and other scenes of a campaign in the king's eighth year. This court is one of the most beautiful objects at Thebes, a colossal statue of Ramses II., broken in pieces, exceeding in its weight and equaling in its dimensions any other known Egyptian statue. It was of a single block of red granite, and must have been transported hither from the quarries of Syene, notwithstanding that its weight was, according to Sir Gardiner Wilkinson's computation, about 887 tons, 54 cwt. (Modern Egypt and Thebes, ii. 144, 145). It was 60 feet in height, representing the king seated on his throne, and was placed on the left side of the entrance to the second court. Of that court, happily, there are more remains than of the first. Its width was about 170 feet and its length about 140, so that it was not much smaller than the other court. It had a double colonnade on each side and at the end, and but a single colonnade at the front. These were of columns having capitals of the form of the papyrus bud, except eight of the ten forming the front row, that is, all of that colonnade but the two extreme columns, and, in like manner, the corresponding ones of the opposite row, which were Cairene pillars, formed of a square block, having in front a figure of Ramses as Osiris. Many of the columns and pillars have been wholly destroyed; but those which yet stand enable us to judge how magnificent this part of the temple must have been. On what remains of the front wall of the court, that is, on its northern half, are very remarkable sculptures. Here is a great scene representing a battle between the Egyptians, led by Ramses II., and the Kheta or Huttees, near the strong city of Kesh. The king of Egypt is portrayed routing the chariots of the enemy, who flee in disorder towards Kesh, across a double moat, beyond which and beneath the city a strong force of regular infantry endeavours to protect their retreat. This was doubtless the decisive action of the campaign against the confederates, which must be regarded as the most important of the wars which distinguished the reign of Ramses II. Higher up on the same wall is a procession of priests bearing small statues of kings, the first of which is that of Menees, the earliest sovereign of Egypt, the second of a Munkt-hopt, of Dynasty XI., and the subsequent ones of the kings of Dynasties XVIII. and XIX., as far as Ramses II., with whom the series ends.

Next to the second court is a hypostyle hall, which is the most admirable part of the temple. It measures 100 feet in length and 135 in breadth, and originally contained forty-eight columns in eight longitudinal rows, each consisting of six columns. A central avenue is formed by twelve lofty columns, about 36 feet high, which have capitals of the shape of the papyrus flower, while the other columns on each side, about 25 feet high, have capitals of the shape of the bud of the same flower. The elegance of the form and the justness of the proportions of all these columns is not equaled in any other Egyptian temple, and render this hall one of the most beautiful structures of its kind. Happily, although much injured, it has suffered less from violence than the first and second courts. On its front wall, to the left as one enters, are curious sculptures, representing the rout of a hostile force, and the capture of a town, the walls of which the Egyptians ascend by means of scaling ladders. Ramses II. and six of his sons lead the army. On the end wall are religious subjects, and a series of the sons and daughters of Ramses II., whose legitimate offspring they seem to have been, twenty-six in number, twenty-three sons and three daughters. At the temple of Wadee-es-Suboo'a, in Nuba, a much larger number of children of this king were represented.

Beyond the hypostyle hall are two smaller chambers, the first of which is entered by a doorway in the middle of the end wall of the hall. It is supported by eight columns, and has on its walls representations of mythological subjects, but is chiefly remarkable, however, for its astronomical ceiling, one of the most precious records of ancient Egyptian science. Behind this is a chamber, which seems to have been of the same dimensions. The other apartments which must have adjoined these are entirely demolished. This temple was the chapel of the king's tomb. The description which Diodorus Siculus gives from Hecataeus of Abdera of the Tomb of Ozymandias agrees best with the Ramesenm of El-Kurneh; and the mention of the sacred library is in accordance with the character of the sculptures of the first chamber beyond the hypostyle hall, as well as with the statement in several papyri that they were written by the scribes in this temple, in which, or attached to which, was a kind of college (Lepsius, Chronologie der Aegypter, i. 39, 53).

To the south-west of the Ramesenm of El-Kurneh, at a distance of less than half a mile, a mound just within the cultivable plain marks the site of a magnificent temple of Amenophis III., which may be called the Amenophum, and which, there is reason to believe, was destroyed by Cambyses. Of the columns and columns which stood on either side of the approach of the Amenophum, all are thrown down except the two gigantic statues, one of which is known as the Vocal Memnon. The latter indeed, was
beneath which is a gateway conducting to the great
temple. On the front of each of the two towers first
mentioned Ramses III, is represented slaying his enemies
before Amen-ra, and below is a series of captured chiefs.
The inscriptions that remain tell us that these are the chiefs
of the Kheta, or Hitites, the Amari, or Amorites, the
Takkara, or Tercianas, the Sharana or the sea, or
Sardones, the Tivabas or the sea, or Tutsans, and of other
peoples. On the walls of the chambers are curious
sculptures usually supposed to represent the private
life of Ramses III., but probably of a mythological import.
Among these the king is portrayed playing at a game
like that of draughts with a goddess, while another
audits by him.

The great temple of Medeenet-Haboo is directly behind
the palace through which was, as already mentioned, the
approach to it, and is a monument of the same kind,
Ramses III., a sovereign inferior alone as a conqueror to
Ramses II., the greatest ruler of Egypt. Both the
magnificence of its architecture, and the high interest of
its sculptures, render it one of the most interesting edifices
at Thebes.

The first propylon cannot be less than 200 feet wide.
It is partly destroyed, and much of it is hidden by the re-
 mains of the town. On its wings the king is represented
singing prisoners before the gods, and acts of worship are
also depicted. The court, of which this propylon is the
front, is about 110 feet in length and 135 in breadth,
and has a colonnade on either side, forming a gallery.
The gallery on the right side consists of seven Osiridean
pillars, that on the left of eight columns having capitals of the
form of the papyrus-flower, affording a remarkable example
of the irregularity of Egyptian architecture. At its end is
a second propylon, on the left wing of which Ramses III.
is represented bringing captives of the Takkara, or
Tercianas, before Amen-ra. Passing through the granite
portal of this propylon we enter the second or peristyle
court, the finest part of the temple. This court measures
about 123 feet in length, and about 135 or somewhat more
in width, thus exceeding in size the first court, contrary to
the usual practice of ancient Egyptian architects. It has
a single colonnade on the front and on either side, and a
double one at the end. The columns at the front and
that facing it are each of eight Osiridean pillars, while
that behind the latter is of columns with capitals of the
papyrus-bud, and the side colonnades consist of each five
similar columns, one of which, on the left side, has fallen.
The Christian inhabitants of the town, the ruins of which
church are seen in the court, defaced many of the
sculptures, and particularly the Osiridean pillars; neverthe-
less the general effect is not lost, and one is struck by a
simple grandeur, which is unsurpassed in any similar
Egyptian structure. The sculptures of the walls are of
special interest. On the back of the left wing of the
propylon a series of sculptures relating to the wars of
Ramses III., begins and extends along the wall on the left
side of the court. The rout of the Rebu or Lebu, the
Libyans, is depicted, the triumphal return of the king, the
bringing of prisoners before him on the field of battle, and
the like; and besides these are subjects portraying cere-
omies. On the right side-wall is a curious representation
of the celebration of the Panegyry of Amen-ra Ka-mut-f
which, from the detail in which it is given, affords us con-
siderable insight into the manner in which such solemnities
were kept (Sac. Eg., iv. pl. 76). On the end wall, and on
each part of each side wall, are depicted the many children of
Ramses III. A door in the end wall conducts to the
inner part of the temple, which occupies but little less
space than the two courts just described. It is in a very
ruined condition.
from the shore. Ramses then receives the praises of which the Egyptian fleet defeated that of the Shardana and end wall the king is portrayed setting forth on an drawn by four oxen. Mercenaires or allies of the Shardana, another small temple of Roman times, having an other battle-scenes of the series represent the capture of the Takkaru and Rebu, before the gods of Thebes. The scenes in sanctuary and other chambers.

Farther in the same direction is an account of them other monuments. Two temples which are situated in the valley, and in two isolated hills, except the Tombs of the mountains, or are excavated in the sides towards the valley, and in two isolated hills, except the Tombs of the Kings, which are cut in the sides of two secluded valleys to the westward.

Beginning from the north, we first see the entrances of grottoes in the low spur of the Libyan chain behind the Soheuem. Several of these have a series of square apertures, leaving pillars to support the roof, so as to form a kind of portico, behind which is a chamber or chambers, having pits, from which open other chambers for sepulture. Some grottoes here, and others extending towards the Rameseum, are inhabited by the people of El-Kurnet-Mara'ee, whose village is ruined. At the foot of the mountains, as well as on their least steep sides, here and throughout the necropolis, are the entrances of many mummy-pits. On the spur above mentioned are brick pyramids, for the most part nearly destroyed; and in the wide tract beyond, the

Asaseef, where the mountains recede, are very remarkable sepulchres of the time of Dynasty XXVI. These are extensive excavations, profusely sculptured almost entirely with hieroglyphics, having before their entrances open courts hewn in the rock, and entered through crude-brick propyla, from which walls of enclosure of the same material extend around the courts. The largest of these, and indeed of all those known at Thebes, is the tomb of Petamen-apt, a priest whose date is not fixed, but who probably lived after the fall of the Ramessides. Sir Gardner Wilkinson says that "the area of the actual excavation is 22,217 square feet, and with the chambers of the pits 23,809, though, from the nature of its plan, the ground it occupies is nearly one acre and a quarter" (Modern Egypt and Thebes, ii. 322). Almost all the passages and chambers are covered with hieroglyphic inscriptions on a small scale, and the few sculptures are of a religious character. At the end of the Asaseef is a temple which was approached by a very long avenue of sphinxes now entirely demolished. The temple is at the base of a steep cliff, and is partly excavated in the rock, and partly built of masonry. The built portion is almost wholly destroyed. A portal of red granite which formed its entrance yet remains, bearing the name of Thothmes III, cut over the erased name of Queen Hatshepu. A second granite portal stands behind this, almost close to the rock. At some distance to the left of this are two small chambers, one of which is remarkable for the form of its roof, which is vaulted by horizontal stones, of which the two uppermost meet in the centre, all being cut internally, so as to form an arch. The excavated part of the temple consists of an oblong chamber of moderate dimensions, another of smaller size with a cell on each side, and at the end a sanctuary. All these, except the sanctuary, are of the time of Queen Hatshepu and Thothmes III, and have vaulted roofs. The sanctuary bears Ptolemaic sculptures, affording a remarkable contrast to the delicate style of those of the chambers which lead to it, and it is flat-rooted. This temple was probably sepulchral.

The isolated hill of the Sheyk'h Abd-Al-Kurneh (probably a mistake for 'Abd-Al-Kurneh, meaning 'the Devotee of El-Kurneh"), presents a singular appearance from the plain, as on that side it is honeycombed by the entrances of tombs. Several of these, like some of those first mentioned, have porticoes before them hewn in the rock, and many have very interesting paintings, representing scenes of domestic life, funeral ceremonies, arts, trades, &c, in their chapel or chapels. These have unfortunately suffered greatly from the disgraceful Vandalism of European travellers, and the cupidity of the natives which they have encouraged. Farther towards Medinet-Haboo is a similar isolated hill, called Kurnet-Mara'ee, which contains a few grottoes of the same description, and in the valley between these and the main mass of mountain are many other interesting grottoes. At one extremity of this valley, at some distance behind the Rameseum, is a small edifice with a high inclosure of crude-brick walls. It is a temple of Athor, of the Ptolemaic period, and has a small portico and three chambers, one of which, the side chamber to the left, is a curious sculpture, of which the subject is the judgment of a soul by Osiris. Hence we may infer that this was a temple attached to the necropolis. Beyond the other extremity of this valley is the secluded valley called that of the Tombs of the Queens, from containing the sepulchres of queens and princesses of Dynasties XVIII., XIX., and XX. These are similar to the Tombs of the Kings, but are not large, nor are the subjects on their walls, which seem generally of little interest, well preserved.

A long and winding valley, the entrance to which is an
The tomb of Rameses III. is among the most splendid of the royal sepulchres. Its length a little exceeds 400 feet, but from the nature of the rock its sculptures are less delicately executed than those of the tomb of Setee L. In cells on either side of its passage, a little within the entrance, are interesting paintings illustrating manners and customs, in one of which is the celebrated representation of the harpers.

The tombs which have been found in the Western Valley are only four in number, but two of these contain paintings, those of Amenophis III. and of King At, the sun-worshipper who succeeded Khu-n-aten. The former is represented with paintings in a very good style, but unfortunately they have sustained much damage; the latter is historically interesting as a record of an obscure king, but its paintings are of poor execution.

Nowhere, perhaps, are we so forcibly struck by the feeling of the ancient Egyptians with respect to death and the future state as in the Valley of the Tombs of the Kings, and in the sepulchres themselves. The desolation of the spot, apart from all signs and sounds of life, fitted it for the solemn use to which it was assigned; and those long dark passages, and lofty chambers, on whose walls we see the awful pictures and the rewards of the good, fitly unveil the most secret mysteries of the Egyptian religion.

Not far south of Thebes, on the western bank, is the large village of Arment, the old Hermonthis, where stands a picturesque temple built by Cleopatra. It has two courts with colonnades, and three chambers around which was also a colonnade, of which but one column now stands. It is of small dimensions, having been the "Typhonium" attached to the great temple of Mentu, the divinity of the place, which has been razed. On the other bank of the river, a little higher, at Tod, anciently Tophium, is a small Ptolemaic temple. Not far beyond, and about 20 miles above Thebes, by the course of the stream, are the "Gebelein," or "Two Mountains," on the western side of the river, where the sandstone begins. The town of Isi, the ancient Sene, called by the Greeks Elkopiopolis, is likewise situated on the west bank, about twelve miles higher, and is remarkable as containing a very fine Egyptian monument, the portico of its great temple of Nephe. This is in the heart of the modern town, and was much choked with rubbish until cleared by Mehemet Ali. It is supported by twenty-four lofty and massive columns, six in front, and four deep, having capitals of various forms, of which those alone in corresponding positions on opposite sides are of the same description, a deviation from regularity of which we do not see examples previous to the Greek rule. The columns and walls are covered with minute sculptures of the bad style of the period when the portico was erected.

—that of the Cessarn. It contains the hieroglyphic names of Claudius, Vespasian, Titus, and other emperors as late as Severus. The back is, however, more ancient, for it bears the name of Ptolemy Philometer, being the front of the older temple of which nothing more is known for certain to remain. Upon the ceiling is a zodiac, from which this monument was supposed to have been of very great antiquity before the interpretation of hieroglyphics had been discovered. On the other bank of the Nile, on the "site of Contra Latopolis, is a small temple of the Ptolemaic and Roman periods.

A few miles above Lins, where both the Libyan and Arabian chains approach the river, are the curious remains of Elathalia (so written in Egyptian geography). There is a small temple of the Ptolemaic time, and two little sacred edifices of the period of the Pharaohs, but the most interesting monuments are the tombs and the fort. The former, which are excavated in a hill, are very remark-
able as illustrating history as well as everyday life, husbandry, &c; and in one of them is the very curious inscription of its occupant Ahmes, chief of the masons, recording his services to early kings of Dynasty XVIII.

The fort as a large inclosure of crude-brick, 1 which was a place of importance as early as the Shepherd war, for it is mentioned as the "Fort of Suben," that is of Eileithyas, is a part of the inscription above mentioned, relating to the time of that war. The goddess of the place was Suben or Lucna (Eileithya), who was especially regarded as the protector of Upper Egypt.

Having proceeded about twelve miles to the southwest we reach the large village of Adfou or Edfin, which represents the town called by the Greeks Apollonopolis Magna, the great temple of which yet stands in a comparatively perfect state, and is one of the most stately monuments of ancient Egypt, although at a time at which it had greatly declined. It was dedicated to Har-hut, the god of the Greeks called Agathodremon. Mounds of rubbish around it, as well as the huts of the village, injured its effect, until it was lately cleared by M. Manette.

The great propylon which forms the front of the temple measures about 226 feet in width, and is, like the rest of the edifice, in a good state of preservation. The sculpture upon its face represents acts of worship by Ptolemy Auletes, who is portrayed slaying prisoners.

The portal between the wings of this propylon is the entrance to the temple of which the first part is a great court about 161 feet long and 140 broad, with a colonnade along its front and each side, of columns with various capitals supporting covered galleries. At the end is a portico having eighteen columns, six in front and three deep, about 82 feet broad and 46 long, measured within, beyond which are a hall and passages and other chambers, the most important of which is an isolated sanctuary. The wall of the great court is continued so as to inclose the further portion of the temple, leaving a passage around it. The sculptures show that it was begun by Ptolemy Philopator and completed at the end of the Greek monarchy, though an insignificant additional subject was added by Claudius.

Not far from the great temple is a smaller one of the sort called Typhonion, containing two chambers, around which runs a gallery supported by Typhonian columns.

The most interesting of the excavations is a rock temple in which is preserved the defeat of a negro nation by King Har-em-heb, or Horus, of Dynasty XVIII., here, also, are subjects depicting acts of worship paid to Nius and Sebek. To the southward of this, and also facing the river, is the entrance of an ancient temple, the representations in which are not of a remarkable character. Beyond these are three chapels of the time of Dynasty XIX. On the opposite side are very important quarries, where much of the material of the great temples was cut, especially under the Eighteenth and subsequent Dynasties.

Beyond Gebel-es-Silulah, although the mountains recede, the tract of cultivated land is extremely narrow, and sometimes the desert touches the river: this is partly owing to the sinking of the level of the stream, which, as already mentioned, was very anciently restrained by some barrier at Siluna. About eleven miles above that place is the extremely picturesque temple of Ombos, placed on a rocky eminence called "Kom-Imbou," "the Hill of Umboon," it stands within a great inclosure of crude-brick walls, which we see on every side, except that towards the river. There is a portal in this wall of the time of Queen Hatshepsut and Thothmes III. The great temple is double, one-half having been dedicated to the worship of Sebek, and the other to that of Har-oer, or Arussa. It consists of a portico of fifteen columns, of which two have fallen, the foremost being connected by a wall of intercolumniation having two entrances, and behind, there is a smaller portico and remains of chambers, including the two sanctuaries.

The earliest name here is that of Ptolemy Philometor (Modern Egypt and Thebes, ii. 282), unless Champollion be right in saying that the name of Epiphanes is also found in the temple (Lettres, 173), and it appears to have been completed by Ptolemy Auletes. There were also remains here of a smaller Ptolemaic temple which have been washed away by the river.

Nothing remarkable occurs between Ombos and Syene, a distance of about twenty miles. The valley is confined to a very narrow space by the mountains, which take bold forms on both sides near the latter place. Just before we reach it, we see the island of Elephantine, where is the famous Nilometer of the Roman time. The town of Aswan, which represents the ancient Syene, stands amid palm-trees on the eastern bank opposite to Elephantine. It is a considerable place, of greater political than of industrial importance, and has succeeded to an older town of the same name, the ruins of which occupy the river's bank and a granite hill to the south. Among them may be mentioned a pier, which has a well, most probably the Nilometer constructed by Amr, the Moslem conqueror of Egypt. In the ruined town is also a small temple of Roman date. Further to the south is its extensive Arab cemetery, which is full of curious tombstones bearing inscriptions in Cufic characters. In the grante hills to the eastward are the quarries whence were taken the obelisks and very many of the statues which adorned the Egyptian temples.

The bed of the river above Aswan is obstructed by numerous rocks and islands of granite, one of the latter of which, that of Saheyi, is interesting on account of the numerous hieroglyphic tablets and inscriptions on these islands.

The most interesting of the excavations is a rock temple in which is preserved the defeat of a negro nation by King Har-em-heb, or Horus, of Dynasty XVIII., here, also, are subjects depicting acts of worship paid to Nius and Sebek. To the southward of this, and also facing the river, is the entrance of an ancient temple, the representations in which are not of a remarkable character. Beyond these are three chapels of the time of Dynasty XIX. On the opposite side are very important quarries, where much of the material of the great temples was cut, especially under the Eighteenth and subsequent Dynasties.

Beyond Gebel-es-Silulah, although the mountains recede, the tract of cultivated land is extremely narrow, and sometimes the desert touches the river: this is partly owing to the sinking of the level of the stream, which, as already mentioned, was very anciently restrained by some barrier at Siluna. About eleven miles above that place is the extremely picturesque temple of Ombos, placed on a rocky eminence called "Kom-Imbou," "the Hill of Umboon," it stands within a great inclosure of crude-brick walls, which we see on every side, except that towards the river. There is a portal in this wall of the time of Queen Hatshepsut and Thothmes III. The great temple is double, one-half having been dedicated to the worship of Sebek, and the other to that of Har-oer, or Arussa. It consists of a portico of fifteen columns, of which two have fallen, the foremost being connected by a wall of intercolumniation having two entrances, and behind, there is a smaller portico and remains of chambers, including the two sanctuaries.

The earliest name here is that of Ptolemy Philometor (Modern Egypt and Thebes, ii. 282), unless Champollion be right in saying that the name of Epiphanes is also found in the temple (Lettres, 173), and it appears to have been completed by Ptolemy Auletes. There were also remains here of a smaller Ptolemaic temple which have been washed away by the river.

Nothing remarkable occurs between Ombos and Syene, a distance of about twenty miles. The valley is confined to a very narrow space by the mountains, which take bold forms on both sides near the latter place. Just before we reach it, we see the island of Elephantine, where is the famous Nilometer of the Roman time. The town of Aswan, which represents the ancient Syene, stands amid palm-trees on the eastern bank opposite to Elephantine. It is a considerable place, of greater political than of industrial importance, and has succeeded to an older town of the same name, the ruins of which occupy the river's bank and a granite hill to the south. Among them may be mentioned a pier, which has a well, most probably the Nilometer constructed by Amr, the Moslem conqueror of Egypt. In the ruined town is also a small temple of Roman date. Further to the south is its extensive Arab cemetery, which is full of curious tombstones bearing inscriptions in Cufic characters. In the granite hills to the eastward are the quarries whence were taken the obelisks and very many of the statues which adorned the Egyptian temples.

The bed of the river above Aswan is obstructed by numerous rocks and islands of granite, one of the latter of which, that of Saheyi, is interesting on account of the numerous hieroglyphic tablets and inscriptions on these islands.

place of Osiris. On the east side is a small but very picturesque temple, nowhypothetical, of the Greek and Roman times, and unfinished. It is 45 feet in width and 63 in length, and has 14 columns with capitals of various forms, connected by intercolumnial walls. The great temple of Isis stands to the westward of this. Its front is formed by a propylon, before which is a kind of court, to be afterwards described. The portal bears the name of Nectanebo II., and the wings were added by the Ptolemies, making the entire width about 122 feet. Through the portal we enter a court, on the right side of which is a gallery fronted by columns, behind which are several small chambers, and on the left side is a separate small temple of Athor, the main entrance to which is by a door and passage in the left wing of the great propylon. This small temple begins with a portico having four columns with the faces of Athor sculptured in high relief upon each of their sides above the capitals. Beyond this are three chambers behind one another, above the door of the first of which is a Greek dedication by Ptolemy Euergetes II., and the second propylon of smaller dimensions is that of Isis, is a temple of the Natron Lakes to the westward of the Roman, and the granite quarries of Gebel-el-Fatehreh. Considerably more to the south, at El-Hammâmis, on the old way from Coptos by Philæ to Portus, are the Breccia Verde quarries, which were much worked from very early times, and have interesting hieroglyphic inscriptions. At Gebel Zâbrâra are emerald mines, now abandoned as unproductive. At the various mines, and on the routes to them and to the Red Sea, are some small temples and stations, ranging from the Pharaonic to the Roman period. Along the shore of the sea are the sites of several ancient ports, the most important of which were Myos Hormos and Berenice, and also the modern town of El-Kuseyr. The northern part of this desert is occupied by the Maâkaâ Arabs and smaller tribes as far as the El-Kuseyr road, beyond which are the Bedouins, a tribe very different from the Arabs in appearance; and to the south of these, to the east of Lower Nubia, is the Bishârî tribe, a people also of African race.

Statistics. 1

[In Egypt, as has been well said, D'État c'est le Khédive. So far as the country itself is concerned the khedive is its personal, absolute, and independent sovereign; but his relations with the Porte are somewhat less simple. When Selim I. of Turkey conquered Egypt in the beginning of the 16th century, the Mameluk power was still too strong for complete subjection, and Selim was obliged to allow his new subjects liberal terms. Egypt still retained practical autonomy, the government being in the hands of a council of Mameluk beys, presided over by a pasha, whose duty it was to look to the annual tribute paid to the Porte, but who possessed little or no actual power. This system was continued till the French occupation, and was re-established when the English army evacuated the country. The Mameluks were still the virtual governors of Egypt, until their massacre by Mehemet Ali. The ambitious designs of this pasha opened the eyes of the Porte to the dangers incurred by so lax a control of a governor unshackled by the council of beys. Menaced with the loss of Syria as well as Egypt, the cause of the sultan was espoused by four of the Great Powers; and the Treaty of 1840, confirmed by the Convention of 1841 limited Mehemet Ali's power to the vice-royalty of Egypt, hereditary for the eldest male of his family, ordered the continuation of the customary tribute, restricted the military and naval strength of the viceroy, and imposed certain other conditions, thus reducing Egypt once more to the state of a Turkish province. But in the reign of the present ruler a change has taken place in the relations between the sultan and his viceroy. A series of expensive negotiations with the Porte, ending with the raising of the tribute from £375,000 to £675,000, procured for Ismail Pasha the title of Khedive, and the right of succession from father to son. The limitation of the Egyptian army

---

1 For much of the information contained in the present section, the writer is indebted to the industrious work of Mr J. G. M'Coon, Egypt in 1840, etc.; though he has thought it necessary to check it with official reports and other authorities, but it must always be remembered that Egyptian like all Oriental statistics can be accepted only with reserve.
and other restrictions which still remained were removed in 1872 by another firman, confirming all the rights previously granted, and giving the khedive every substantial attribute of sovereignty, except only the pasha legatums. The khedive is therefore virtually an independent sovereign, holding his power on the easy tenure of tribute and military aid in case of war.

The real work of governing is entirely performed by the pasha legatums, the agents, not the rulers, of the khedive. The Privy Council, presided over by the Prince Hereditary Mehemet Tawfik Pasha, and consisting of the ministers, the Sheykh al-Islam, and some other functionaries, examines and reports to the khedive on the work of the several departments. The eight ministries are those of (1) Finance, (2) Foreign Affairs, (3) Interior, (4) War, (5) Marine, (6) Commerce, (7) Public Works and Agriculture, and (8) Public Instruction. Besides these there are the sub-departments of the Customs and Post-Office.

The provincial administration (exclusive of the separate governments of the eight “cities”) is divided among the muhirs of the fourteen prefectures, the Feiyoom now being one, each subdivided into departments and communes, or cantons including several villages, governed by ma-moors, nárs, or sheyks, el-beled, appointed by the Government and assisted and checked by councils of agriculture and an administrative council for each canton.

In 1867 the Assembly of Notables was revived, consisting of village sheyks, do, elected by the communes and meeting once a year to receive from the Privy Council a report of the twelvemonth's administration. Although the Assembly has not yet attained to the full dignity of parliamentary power, it has considerable weight in the control of state measures.

By the Convention of 1841 the Egyptian army was limited to 18,000 men, but this was raised to 30,000 by the firman of 1866, and now all restrictions have been done away. The present force may be placed at an average peace strength of 30,000 men, regulated, however, on a short service system, so that not more than half this number are generally at one time with the colours. This army consists of 18 regiments of infantry, 3 battalions each; 4 battalions of riflemen; 4 regiments of cavalry, 6 squadrons each; 4 of field artillery, 6 batteries each (2 mounted), 3 of garrison artillery; and 3 battalions of pioneers. The infantry are armed with the Remington rifle; the cavalry with revolver and lance, or sabre and carbine; the field artillery with 100 Krupp guns and 50 smooth-bore. Besides these there is a reserve of 30,000 men, and an irregular contingent of 60,000 mounted Bedawees. The army is raised by conscription, irregular forces being held every two or three years. All Egyptians of any creed are liable to conscription, except only the inhabitants of Cairo and Alexandria; but immunity may be purchased by payment of a tax. The monthly pay ranges from 20 piastres (= 4s. 2d.) for a private, to £5 (Egyptian) for a captain, £40 for a full colonel, and £75 for a field general. Under the training of French and American officers, the army has been brought into an admirable state of discipline and efficiency.

The Egyptian navy hardly deserves notice. It consists at present of 3 frigates, 2 corvettes, 4 gunboats, and 2 sloops, all unarmed.

Mehemet Ali devoted considerable attention to the establishment of colleges and military schools, besides sending young men to Europe for purposes of scientific study. In Cairo and its environs he founded several elements of the system of educational arrangements, as schools of a higher order than the native schools of the same class; a school of languages; a printing press at Boolak, from which many valuable publications have issued, and a school of medicine at Kasr-el-Eynee, between Cairo and Maar-el-Ateekah, which has done excellent work. At El-Khankah and in its neighbourhood he placed a military hospital, a school of medicine, a veterinary college, an agricultural school, and a school of music, at El-Geezeh a cavalry school, and at Turá one of artillery. These and similar establishments were well designed and ably carried out. When Mehemet Ali's ambitious designs were defeated in 1840 by the action of the Powers, his educational reforms languished, and under Abbas the schools were closed and everything returned to the old system. Said Pasha endeavoured to revive Mehemet Ali's improvements, but it was reserved for the present khedive entirely to carry out his grandfather's designs. Besides the revived and newly created military schools, there are two systems of education in Egypt—by the schools established and supported by the Government, and by the old system of mosque educator and Arab primary schools, besides the numerous establishments of the non-Muslim communities. The Government schools are nine in number—the Polytechnic, Book-keeping and Surveying, Law and Languages, Industrial, Medical, Midwifery, two preparatory schools at Cairo, and one at Alexandria. Besides these the Government supports a school for the blind, a normal school, two girls' schools, three industrial schools, and 23 municipal schools. At the Polytechnic School the course extends over six years, and includes the higher mathematics, chemistry, physics, geology, mechanics, geography, history, drawing, Arabic, and English or French.

Of the mosque colleges, the greatest, not only in Egypt but in the whole Mohammedan world, is the Azhar, where over 11,000 students, coming from every quarter of the Muslim empire, are instructed by 330 sheyks in the old curriculum of Muslim acquirement. The Arab primary schools, 4000 or 5000 in number, are the regular providers of education for the fellaheen, who pay either nothing at all, or a merely nominal sum, for being taught to read and recite the Koran, and sometimes writing and very elementary arithmetic. How greatly the educational system in Egypt has been enlarged of late may be judged from the fact that, under Said Pasha it hardly cost the Government £4000 a year, whilst the educational budget (exclusive of the military schools) now reaches the sum of £40,000, to which the khedive adds £12,500, making a total of £52,500.

Of the schools of non-Muslim communities the Copts have 16, the Greeks 4, the Armenians 1, and the Jews several academies. Besides these there are two undenominational “Universal Schools,” of foreign foundation, where a moderate education, without religious instruction of any kind, is given to all comers, and many schools founded by the American Board of Missions, and Miss Whately's admirable British Mission School. The proportion of girls' schools is extremely small, but their existence, and the fact that they receive the warmest support of one of the waves of the khedive, is a hopeful sign.

The public works carried out in Egypt during the present reign would fill a long catalogue, without reckoning the Suez Canal, for an account of which see CANAL, vol. IV. p. 789. Railway communication has been established between Alexandria, Cairo, Damietta, the Feeyoom, and Aasytou, the various lines covering over 1200 miles. A Soudan railway, from Wadcc Halieh to Hannek, and from near Dunkallah to Khartoom, involving costly and difficult engineering for a length of more than 1000 miles, has been begun with the view of intrusting the passage to India, and bringing the produce of the rich southern soil into easier connection with Cairo; these works are, however, at present at a standstill. The canal
system has been greatly enlarged and improved, but a still better result is anticipated from the barrage of the Nile, a plan projected by M. Mougel and now about to be carried out for the khedive by Mr. Fowler. In 1871 the work of building a breakwater to defend the New Harbour at Alexandria from the sea caused by the constant south-west winds was begun. The outer breakwater extends above two miles across the mouth of the harbour, inclosing an area of 1400 acres of calm water. The structure rises 7 feet above the highest sea-level, and is of a uniform width of 20 feet. Harbour works have also been constructed at Suez. At a cost of over £160,000, four large light-houses have been erected, seven on the Mediterranean coast, seven on the Red Sea, whereas at the beginning of the reign of the khedive there was but one. Telegraph lines (begun by the enterprise of Said), have been set throughout Egypt, covering nearly 6000 miles, and putting Alexandria into direct communication with Kartoum; and thus branch of the public service is managed by English officials. Submarine telegraphs also bring Egypt into communication with Candia and thence with Constantinople and Otranto, and with Malta thence with England, France, &c. The post-office was bought by the Government in 1863, and under the management of an English post official has been greatly improved. In about 70 towns and villages offices have been established, and several mails a day are despatched from the chief places.

The manufactures of Egypt have been in a declining state for several centuries. Mehemet Ali tried to promote them, by establishing large manufactories of cotton, silk, and woollen goods, turabooshes, &c., and, especially in Upper Egypt, sugar-refineries. Ibrahim Pasha was much opposed to his father's policy, and in pursuance of his own views he laid out extensive plantations of olive and other trees, erected powerful steam-engines for the irrigation of his lands, and on all his estates endeavoured to encourage agriculture. It cannot be doubted that had he lived the correctness of his conviction that Egypt is an agricultural, not a manufacturing, country would under his rule have been fully verified. Mehemet Ali introduced cotton and largely cultivated it; the Turkish grandees found that from it they could extract more gain than from other field produce, and large tracts were speedily devoted to its culture. The necessity, however, of excluding the waters of the Nile has caused several destructive inundations; and so long as the cotton growth remained a monopoly of the pasha it was no means of enrichment to the producer. Now, however, that the monopoly is abolished, the trade in cotton is greatly increasing, and this produce will undoubtedly become every year a more important item in the wealth of the country. The old restrictions upon agriculture have been more or less done away; and the Government, whilst not wholly abandoning Mehemet Ali's views on manufactures, is yet alive to the paramount importance of affording every encouragement to agriculture.

The cotton crop in 1875 extended over 871,847 feddans (≈ acres, nearly) and produced 2,815,841 quintals (≈ 110lbs. of grain) of graded staple, 1,654,555 ardebbs (of 5 kussas each) of seed, and 374,246 loads of cotton sticks, altogether reaching a total value of about two millions and a quarter. The wheat crop in the same year was estimated at 6,665,628 ardebbs, of the value of £1,756,058; maize (duriel), 10,105,715 ardebbs, £281,193,000; beans, 4,176,573 ardebbs, £24,575,773; barley, 3,108,085 ardebbs, £32,294,000; rice, 95,521 ardebbs, £27,289,008. The other crops of Egypt are chiefly clover, sugar-cane, flax, hemp, tobacco, henna, and indigo.

The revenue is derived chiefly from the land-tax, the tax on date-trees, trade licences, the customs, the tobacco duties, railways, and the Mukabalah (of which an account will be given), and village annuities. Of these the land-tax is the principal item, amounting to nearly half the total revenue; but this will be considerably reduced when the Mukabalah comes to an end (in 1885). The whole revenue may at present roughly be placed at £10,500,000. It is very difficult to estimate the exact amount of direct taxation on the population. One writer places it at 25a., per head per annum; whilst a recent report states that, including the Mukabalah, the annual payment of taxes has lately reached £4,444. It is certain the taxation at present exceeds the possible returns of the land, and that the fellahen are compelled to borrow money to pay the taxes. The items of expenditure may thus be roughly summarized:—

During the last fifteen years Egypt has acquired the enormous national debt of about £20,393,000. The attempt to Europeanize the country has entailed a vast expenditure. Public works have been carried out at an altogether unnecessary rate of speed, and European contractors have been employed who have not scrupled to drive bargains exceedingly favourable to themselves and ruinous to the Egyptian Exchequer. To these causes of expenditure must be added the dishonesty and extravagance of the Government officials, the waste of money on works which have proved unproductive and useless, and the heavy damages given against the khedive in the extraordinary award of the late emperor Napoleon as arbitrator in the dispute with the Suez Canal Company. To meet the heavy expenses resulting from these causes, five loans have from time to time been raised.

The first was borrowed by Said Pasha in 1862, and amounted to only £3,292,600 nominal, to be repaid in thirty years, interest 7 per cent, and sinking fund 1 per cent. The present viceroy then raised the 1864 loan of £3,804,200 nominal, with interest and sinking fund at 7 and 3 per cent, redeemable in 36 years.

The next loan, of 1868, redeemable in 1898, was for £11,890,000 nominal (of which only £7,193,334 was received), with apparent interest and sinking fund at 7 and 3 per cent, really 25 and 12½ per cent, on amount received, or altogether 32 per cent.
The result was a scheme which the Right Honourable G. J. Goschen, M.P., then urged upon him with so much eloquence that the state debt was thus divided into three parts, and the three small loans, interest 7 per cent, redeemable at 80 in 100, and the three short loans, interest 5 per cent, were paid off by the Mubakalah. Besides these, there was the private Daira debt of the khedive. The scheme is perhaps the best that can be devised under the present perplexing conditions, and if the Egyptian Government can maintain its revenue and will hold to its engagements there is every probability that the debts will be paid off at the appointed times. When the Mubakalah fails in 1885 the three short loans will (presumably) have been paid off. This preference debt is to be redeemed in 55 years by the operation of a sinking fund of £35,744 a year, and the united debt in the same time and after a similar manner. With a view to insure the carrying out of these reforms, the khedive has appointed English and French controllers-general, who are instructed to collect the revenue and the appropriation of it to the purposes settled by the financial scheme. A European Commission of the Public Debt has also been appointed for receiving the revenue devoted to the payment of the debt charges, and another High Commission, composed of three Europeans and five natives, controls the railways and the port of Alexandria. So long as the present arrangement is held to, and if no unforeseen decrease takes place in the revenue, the financial position of Egypt may be considered hopeful. The khedive has been the subject of much censure at the hands of his bondholders. It must however be remembered that he received but half of the sums supposed to have reached him. Of the £45,000,000 received he has paid back over £30,000,000 in interest, &c., and £10,000,000 went in the Suez Canal indemnity, so that only £4,000,000 could have been squandered. That the khedive is no financier is obvious, but he seems honestly determined to pay his debts, and if there was any ulterior motive in the matter of the loans it was not on the khedive's side.

The principal exports from Egypt are cotton, cereals, and sugar. In 1875, 153,912,536 lb. of raw cotton was exported to Great Britain, at the value of £6,685,340, and the total cotton export is estimated at over two millions and a half of quintals. Of beans, 480,357 arsebs were exported in 1875, of which, 326,912 were barley, 98,666 quintals. Mace, barley, flax, cotton, dates, hemp, and other produce form less important items in the list of exports. The total value of exports is estimated at between twelve and thirteen million pounds. The imports are estimated at about five millions and a half of pounds and consist chiefly of manufactured goods, coal, oil, wine, machinery, &c. Of the whole commerce about 25 per cent is with Great Britain. There is also a considerable transit trade, which, however, has necessarily diminished since the opening of the Suez Canal.

The Egyptian measures are— the foot, or space measured by the extension of the thumb and first finger; the cubit, or span; and the cubit (of three kinds, — 22 in, 25, and 26½ inches). The measure of land is the feddan, very nearly equal to the English acre, subdivided into 24 khebets, and each of these into 330 (formerly 3334) kashebs, or rods, the kasheb being a square measure with sides of 22 khebets, each equaling 6½ inches. The ardeb is equal to about 5 bushels, and is divided into 6 weybehs, and each weybeh into 24 rubas.

The weights are these:—

64 krombahs (or gruas of wheat), or 48 habbehs (or gruas of barley) = 1 durbah (= 4½ s 'Troy').
12 durbahs = 1 wukeh or vaceh (about 575 gr.)
12 wukeh ors = 1 ratl or pound (= 15 oz. 13 dr. avoirdupois.)
210 ratls = 1 wukkah or oke (= 22 lb.)
36 wukkahs = 1 kantar or quart (= 16 lb.)
24 keebas = 1 mithkal or weight of a demir (= 72 gr.)

The French metrical system has been established by the khedive, but it has not yet been generally adopted.

The standard unit of currency is the kharsh, or piastre (about 25 c.,) which is coined in gold pieces of 5, 10, 20, 25, 50, 100 piastres : silver of 1, 2½, 5, 10, 20 piastres.
Copper coins of 5, 10, 20 para (or faddals, 40 to the piastre) and 1 piastre are also coined. The kee, or para, of 800 piastres, is equal to about £4, 2s. 6d. The khamze, or treasury, consists of 1000 para. 97½ piastres are given for the English pound sterling. Besides the regular Egyptian currency, European coins of all kinds are commonly employed in Egypt, especially the English sovereign, the French Napoleon, the Venetian sequin, the Spanish doubloon and dollar, the 5-franc piece, and the Constantine coin.

INDEX TO ARTICLE EGYPT.

EHRBREITSTEIN, a small town in Prussia, in the circle of Coblenz, situated on the right bank of the Rhine, and connected with the town of Coblenz by a bridge of boats, is of importance as possessing a magnificent fortress erected upon a precipitous rock 401 feet above the boa.ts, is of importance as possessing a magnificent fortress.

Scientific Society of Göttingen, and in 1819 Oeheimer Justizrat of Hanover. His health was shattered by an attack of inflammation of the lungs in the year 1819, but he regularly continued his prelections to a large number of students until attacked by fever on the 14th June 1819. He died on the 27th of that month. Eichhorn is the author of a good many historical works, but it is as a biblical critic that he is best known. He may almost be said to have originated the science of biblical criticism, for he first properly recognized its scope and the problems it had to solve, and began many of its most important discussions. He was the first to see the necessity of finding a firm historical foundation for everything in Christianity that was to be accepted as fact. Preliminary to his endeavours towards this end, he took for granted that all the so-called supernatural facts relating to the Old and New Testaments were explicable on natural principles. He sought to judge them from the standpoint of the ancient world, and to account for them by the superstitious beliefs which were then generally in vogue. He did not perceive in the biblical books any religious ideas of much importance for modern times; they interested him merely historically, and for the light they cast upon the Old Testament and some of the Epistles, and he was the first to suggest that the Gospels were compiled by later writers from documents which have now perished. He did not appreciate as sufficiently as Strauss and the Tubingen critics the difficulties which a natural theory has to surmount, nor did he support his conclusions by such elaborate argumentation. Gott. He regarded as ungenuine many books of the Old Testament, and some of the Epistles, and he was the first to have found the necessity of finding a firm historical foundation for everything in Christianity that was to be accepted as fact. Gott.
both Icelanders and Norwegians. In the Old World the Eider breeds in suitable localities from Spitsbergen to the Parn Island, and the coast of Jutland—where it is known as St Catherines Duck. Its food consists of marine animals (mollusks and crustaceans), and hence the young are not easily reared in captivity. The Eider of the New World differs somewhat from our own, and has been described as a distinct species (S. drasseri), one of which (the latter) also inhabits the Arctic coast of Russia and East Finnmark and has twice reached England. The Labrador Duck (S. labradorica), which is now believed to be extinct (see Brans, vol. iii. p. 735), also belongs to this group. (A. N.)

EILENBERG, a town in the province of Saxony, government of Meissen, circle of Delitzsch, is situated on an island formed by the Mulde, about 29 miles north-east of Leipzig. The principal structures are the hospital, the infirmary, three churches, and the castle. From the last-mentioned, formerly known as Ilberg, and in the time of Henry the Fowler an important post of defence against the Sorbs and Wends, the town received its name. The industries include the manufacture of chemicals, cloth, quilting, calico, cigars, and agricultural implements, bleaching, dyeing, wax-refining, brick-making, and trade in cattle. In the neighbourhood is the iron-foundry of Finster.

ELLENBURG, a town in the west circle of the duchy of Saxo-Altenburg, in the province of Hainichen, government of Meissen, circle of Delitzsch, is situated on the Horsel, 39 miles north-east of Leipzig. The principal structures are a cathedral, a castle, the town-hall, hospitals, and a town-house, erected in 1641. Elsenach has a manufactory for cotton cloth, and a large woollen and several other mills. Population in 1875, 16,133.

ELSENACH, a town in the west circle of the duchy of Saxo-Altenburg, and 24 miles W.S.W. of Altenburg. It is old, and has changed possessors more than once, but was joined to Saxo-Altenburg in 1826. It possesses an old castle and a beautiful church. Its industries are principally woollen and porcelain manufactures, linen-weaving, and shoe-making. Population in 1875, 5,509.

It possesses an old castle and a beautiful church. Its industries are principally woollen and porcelain manufactures, linen-weaving, and shoe-making. Population in 1875, 5,509.

ELEICHA, the capital of the Eisenach circle and of the administrative department of Saxe-Weimar-Eisenach, lies in a romantic district at the north-west end of the Thuringian wood. It is situated on the Horsel, at the junction of the Thuringian and Werra railways, and 44 miles west from Weimar. In its neighbourhood is the Warburg, where Luther on his return from the Diet of Worms was imprisoned, and where from May 1521 to March 1522 he devoted himself to the translation of the Bible. On a high rock on the south side of the town are the ruins of the castle of Madelstein. Eisenach is the birth-place of Sebastian Bach, and he and Luther were educated at its gymnasium, then the Latin school. Among the public buildings may be mentioned the tower of St Nicholas, the castle; rebuilt in 1742, and the town-house, erected in 1641. Eisenach has a manufactory for cotton cloth, and a large woollen and several other mills. Population in 1875, 16,133.

EISENBERG, a town in the west circle of the duchy of Saxo-Altenburg, and 24 miles W.S.W. of Altenburg. It is old, and has changed possessors more than once, but was joined to Saxo-Altenburg in 1826. It possesses an old castle and a beautiful church. Its industries are principally woollen and porcelain manufactures, linen-weaving, and shoe-making. Population in 1875, 5,509.

It possesses an old castle and a beautiful church. Its industries are principally woollen and porcelain manufactures, linen-weaving, and shoe-making. Population in 1875, 5,509.
EIS—EIS

EISLEBEN (Latin, Isleba), the chief town of the Mansfield circle, in the government of Merseburg, province of Saxony, Prussia, is situated on the railway from Halle to Nordhausen and Cassel, 15 miles west from Halle. It consists of an old and a new town, the former being surrounded by walls. In the vicinity are extensive copper and silver mines, and the town itself possesses smelting furnaces, several breweries, and manufactories of linen, tobacco, and woollen.

Among its principal buildings are—the old castle, the church of St Andrews, which contains numerous monuments of the counts of Mansfield, the church of St Paul and St Peter, in which is the font where Luther was baptized; the Royal Gymnasium, founded by Luther shortly before his death in 1546, and the hospital. Eisleben is celebrated as the place where Luther was born and died. The house in which he was born was burned in 1689, but was rebuilt in 1693 as a free school for orphans; that in which he died has lately been renovated, and his death-chamber is still preserved.

The first mention of Eisleben dates from the 11th century. During the insurrection of the peasants in 1525, it was partly destroyed, and it was immediately after this that the new town was founded. In 1788, when the township of Mansfield House was extinct, Eisleben came into the possession of Saxony, and in 1815 of Prussia. The population in 1875 was 14,378.

EISTEDDFOD, Yn (plural Eisteddfodau), the national bardic congress of Wales, the objects of which are to encourage bardism and music and the general literature of the Welsh, to maintain the Welsh language and customs of the country, and to foster and cultivate a patriotic spirit amongst the people. This institution, so peculiar to Wales, is of very ancient origin. The term Eisteddfod, however, which means “a session” or “a sitting,” was probably not applied to bardic congresses before the 12th century.

The Eisteddfod in its present character appears to have originated in the time of Owain ap Maxen Wledig, who at the close of the 4th century was elected to the chief sovereignty of the Britons on the departure of the Romans. It was at this time, or soon afterwards, that the laws and usages of the Gorsedd were codified and remodelled, and its motto of “Y gwyr yn erbyn y byd” (“The truth against the world”) given to it. “Chairs” (with which the Eisteddfod as a national institution is now inseparably connected) were also established, or rather perhaps resuscitated about the same time. The chair was a kind of convention where disciples were trained, and bardic matters discussed preparatory to the great Gorsedd, each chair having a distinctive motto. There are now existing four chairs in Wales,—namely, the “royal chair of Powys,” whose motto is “A laddo a leddir” (“He that slayeth shall be slain”); that of Gwen and Glamorgan, whose motto is “Dduw a phob daimon” (“God and all goodness”); that of Dyfed, whose motto is “Calon wrth galon,” (“Heart with heart”); and that of Gwynedd, or North Wales, whose motto is “Gwen” or “O leu! ma’g gamwth” (“Jesus, or Oh Jesus! suffer not iniquity”).

The first Eisteddfod of which any account seems to have descended to us was one held on the banks of the Conway in the 6th century, under the auspices of Maelgwn Gwynedd, prince of North Wales. Maelgwn on this occasion, in order to prove the superiority of vocal song over instrumental music, as recorded to have offered a reward to such bards and minstrels as should swim over the Conway. There were several competitors, but on their arrival on the opposite shore, the harpers found themselves unable to play, owing to the injury their harps had sustained from the water, while the bards were in as good tune as ever.

Griffith ap Cynan, prince of North Wales, who had been born in Ireland, brought with him from that country many Irish musicians, who greatly improved the music of Wales. During his long reign of 56 years he offered great encouragement to bards, harpers, and minstrels, and framed a code of laws for their better regulation. He held an Eisteddfod about the beginning of the 12th century at Caerwys in Flintshire, “to which there repaired all the musicians of Wales, and some also from England and Scotland.” For many years afterwards the Eisteddfod appears to have been held triennially, and to have enforced the rigid observance of the enactments of Griffith ap Cynan. The places at which it was generally held were Aberffraw, formerly the royal seat of the princes of North Wales, Dynevor, the royal castle of the princes of South Wales, and Machynlleth, the royal palace of the princes of Powys, and in later times Caerwys in Flintshire received that honourable distinction, it having been the princey residence of Llewelyn the Last. Some of these Elbteddfodau were conducted in a style of great magnificence, under the patronage of the national princes. At Christmas 1197, Cadwgan, the son of Bleddyn ap Cynfyn, prince of Powys, held an Eisteddfod in Cardigan Castle, to which he invited the bards, harpers, and minstrels, “the best to be found in all Wales,” and “he gave them chairs and subjects of composition according to the custom of the feasts of King Arthur.” In 1175 Rhys ab Gruffydd, prince of South Wales, held an Eisteddfod in the same castle on a scale still greater magnificence, it having been proclaimed, we are told, a year before it took place, “over Wales, England, Scotland, Ireland, and many other countries.”

On the annexation of Wales to England, Edward I deemed it politic to sanction the bardic Eisteddfod by his famous statute of Rhuddlan. In the reign of Edward III for Hael, a South Wales chieftain, held one at his mansion. Another was held in 1431, with the permission of the king, by Griffith ab Nicholas at Carmarthen, in princely style, where Dafydd ab Edmund, an eminent poet, signalized himself by his wonderful powers of versification in the Welsh metres, and whence “he carried home on his shoulders the silver chair” which he had fairly won. Several Eisteddfodau were held one at least by royal mandate in the reign of Henry VII. In 1523 one was held at Caerwys before the chamberlain of North Wales and others, by virtue of a commission issued by Henry VIII. In the course of time, through relaxation of bardic discipline, the profession was assumed by unqualified persons, to the great detriment of the regular bards. Accordingly in 1567 Queen Elizabeth issued a commission for holding an Eisteddfod at Caerwys in the following year, which was duly held, when degrees were conferred on 55 candidates, including 20 harpers. From the terms of the royal proclamation we find that it was then customary to bestow “a silver harp” on the chief of the faculty of musicians, as it had been usual to reward the chief bard with “a silver chair.” This was the last Eisteddfod appointed by royal commission, but several others of some importance were held during the 16th and 17th centuries, under the patronage of the earl of Pembroke, Sir Richard Neville, and other influential persons. Amongst these the last of any particular note was one held in Bewyer Castle, Glamorgan, by Sir Richard Basset in 1681.

During the succeeding 100 years Welsh nationalty was at its lowest ebb, and no general Eisteddfod on a large scale appears to have been held until 1819. Though several
small ones were held under the auspices of the Gwynedd-digon Society, established in 1771,—the most important being those at Corwen (1769), St Asaph (1790), and Caerwy (1798). At the close of the Napoleonic wars, however, there was a general revival of Welsh nationality, and numerous Welsh literary societies were established throughout Wales, and in the principal English towns. A large Eisteddfod was held under distinguished patronage at Carmarthen in 1819, and from that time to the present day they have been held, almost without intermission, annually, several of them being held under royal patronage. The following is a list of the principal Eisteddfodau since that date:

1820, Wrexham; 1821, Carnarvon; 1822, Brecon; 1823, Carmarthen; 1824, Welshpool; 1825, Brecon; 1826, Denbigh, 1827, Beaumaris; 1828, Cardiff; 1829, Llanerchymedd; 1836, Liverpool; 1835, Merthyr; 1839, Liverpool; 1840, Aberavon; 1842, Swansea; 1845, Aberavon; 1849, Aberpenna; 1850, Rhuddlan; 1851, Tremadoc; 1852, Liverpool and Pembroke; 1854, Festiniog; 1855, Dyne Fawrddyr, Machynlleth, and Morriston, 1858, Llangollen (memorable for the ancient ceremonies and restoration of the ancient bardic traditions, bardic, bardoc), 1859, Meirion, 1859, Denbigh, 1860, Denbigh; 1861, Conway and Aberdare, 1862, Carnarvon; 1863, Swanses and Rhyl, 1864, Llandscnnt, 1865, Aberystwith; 1867, Chester; 1868, Carnarvon; 1869, Rhos; 1870, Llanerchymedd; 1870, Rhyl, 1871, Towyn; 1872, Pembroke; 1873, Mold; 1874, Bangor; 1875, Pwllhele, 1876, Wrexham; and 1877, Carnarvon.

Besides these, innumerable local Eisteddfodau have been held during the last 50 years. To constitute a provincial Eisteddfod it is necessary that it should be proclaimed by a graduated bard of a Gorsedd a year and a day before it takes place. A Gorsedd is a corporation about the beginning of the reign of Edward III, as a remedy to a lessee who for years had been ousted of his term. It was a writ of trespass, and 'carried damages, but in course of time the courts of common law added thereto 'a species of remedy neither warranted by the original writ nor demanded by the declaration, viz., a judgment to recover the term and a writ of possession upon.' The next step was to extend the remedy to cases of disputed title to freehold. This was done indirectly by the claimant entering on the land and there making a lease for a term of years to another person; for it was only a term that could be recovered by the action, and to create a term required actual possession in the grantor. The lease remained on the land, and the next person who entered even by chance was accounted a tenant, which was the title, and then served upon him a writ of trespass and ejectment. The case then went to trial as on a common action of trespass; and the claimant's title, being the real foundation of the lessee's right, was thus indirectly determined. These proceedings might take place without the knowledge of the person in possession; and to prevent the abuse of the action a rule was laid down that the plaintiff in ejectment must give notice to the party in possession, who might then come in and defend the action. When the action came into general use as a mode of trying the title to freehold, the actual entry, lease, and ouster which were necessary to found the action were attended with much inconvenience, and accordingly Lord Chief-Justice Rolle during the Protectorate substituted for them the fictitious averments already described. The action of ejectment is now only a curiosity of legal history. Its fictitious suitors were swept away by the Common Law Procedure Act of 1852. A form of writ was prescribed, in which the person in possession of the disputed premises by name and all persons entitled to defend the possession were informed that the plaintiff claimed the disputed property, and as the plaintiff was required to appear in court to defend the possession of the property or such part of it as they should think fit. In the form of the writ and in some other respects ejectment still differed from other actions. But now by the Judicature
Act, 1875, all actions are begun and carried on in the same manner, and an action for the recovery of land will, with very few exceptions, proceed in the same manner as any other action.

EKATERINBURG, or YEKATERNBURG, a town of Asiatic Russia, at the head of a department in the province of Perm, on the Siberian highway, about 238 miles to the south-east of Perm, in 56° 49' N. lat. and 60° 35' E. long. It is situated near the eastern skirt of the Ural Mountains, and occupies both banks of the Iset, which is there crossed by a dam and forms a valuable reservoir for industrial purposes. In 1834 it was made the seat of a suffragan bishop, and it has long been the head-quarters of the administration of the mines, not only for the immediate neighbourhood, but also for the big-gazol, Goroblaggodat, Perm, Zlatoostoff, and Kaban-Votkins districts. The streets are broad and regular, and several of the houses of patanal proportions. There are two cathedrals—St Catherine’s founded in 1785, and Epiphany in 1774, with more than a dozen churches and a monastery, two gymnasiunm, a departmental school, a city infirmary, a workmen’s hospital, an almshouse, a children’s home, a prison, a theatre, and a museum opened in 1853. Besides the Government mint for copper coinage, which dates from 1735, the Government engineering works, and the imperial factory for the polishing of malachite, jasper, marble, porphyry, and other ornamental stones, the industrial establishments comprise tallow-factories, soap-works, glue-works, rope-works, distilleries, potteries, and carriage factories. The trade is very extensive, especially in cattle, grain, iron, woolen and silk stuffs, and colonial wares; and besides a weekly market there are two annual fairs. The population in 1866 numbered 19,832, mostly belonging to the Greek Church, only 47 being Catholics, 198 Protestants, and 36 Mahometans, in 1871 it had increased to 25,323.

Ekaterinburg took its origin from the mining establishments founded on the spot by Peter I. in 1723, and received its name in honour of Catherine I. Its development was greatly promoted in 1763 by the Siberian highway, which till then had passed by Verkhnetobolsk, being diverted so as to pass through it; and the gradual extension of mining operations in the district has maintained its prosperity. In 1781 the town was transferred from the Tobolsk department to the government of Perm, and in 1833 passed from the jurisdiction of the Administration of Mines to the ordinary civil jurisdiction.

EKATERINODAR, the chief town of the Russian government of Kuban, on the right bank of the Kuban, near the confluence of the Karsau, in 45° 3' N. lat. and 35° 14' E. long, 1400 miles from St Petersburg and 555 miles north west of Tiflis. It is badly built on a swampy site exposed to the inundations of the river; and its houses, with few exceptions, are slight structures of wood and plaster. Six churches, a gymnasium, two schools, and a hospital are the principal public buildings. None of the industrial establishments, which comprise soap-works, tanneries, brick-works, and potteries, are of more than local importance; but there is a fair trade in horses, cattle, sheep, wool, and fish. In the neighbourhood is a large garden and orchard maintained by the Government for the encouragement of horticulture. The town dates from the reign of Catherine II., when in 1792 the Zaporogian Cossacks were transferred to the Kuban district. In 1860 the population amounted to 9620, mainly Cossacks; in 1871 it was 17,622.

EKATERNOSLOFF, or EKATERNOSLAVSKAYA GUBERNIA, a government of Southern Russia, which lies partly to the W. of the Don, stretches E. to the Donetz and the Kalmius, and in the S. reaches the Sea of Azoff between the mouths of the Berda and the Kalmius. It is watered by the Donieper for 200 miles, and bounded by the Donetz for 192. The district of Rostoff, lying round the head of the Gulf of Taganrog, though naturally a portion of the Country of the Don, is also assigned to Ekaternosloff. According to the military survey, the area of the government is 26,055 square miles, or 59,185 square versts; according to Schweizer, only 25,644 square miles, or 58,538 square versts. Its area is a steppe-like plain, relieved here and there by considerable elevations, and traversed by deep ravines and river courses. The most important range of hills, or those forming the water-shed between the tributaries of the Donetz and the independent affluents of the Sea of Azoff, attains no greater height than 530 feet above sea-level. A line drawn from near the mouth of the Orel parallel with the Dnieper as far as the town of Ekaternoslof, and thence to the village of Karakob on the Kalmius, divides the government into two geographical districts, of which the south-western is distinguished by crystalline and the north-eastern by sedimentary rocks.

Of the former the predominant variety is gneiss, interrupted by numerous upheavals of granite, syenite, diorite, and serpentine. The latter belong to several different formations. Carboniferous strata occupy the greater part of the districts of Slavianoosorsk and Bakhmout and part of Pavlograd and Alexandrof; Permian strata occur within a very limited area in Bakhmout. Cretaceous strata form a narrow strip along the northern boundary of the government from Bakhmout to the confluence of the Orelka and the Orel, and Tertiary strata extend through nearly all the district of Novomoskovsk and the southern part of Pavlograd. The mineral deposits of the government are of great value. Anthracite and coal are distributed along the northern Donetz, the Logun, the Miuschik, the Kalmius, and various other streams. The quantity of coal obtained in 1861 exceeded 1,200,100 puds. Iron ore is present in the same districts, and is successfully worked in several places, as at the Government establishments on the Logun. Excellent whetstone is procured in the Slaviansoorsk district, and transported throughout Russia. Asbestos, millstones, gypsum, marl, and rock salt, as well as building materials, are among the minor products. There are altogether about 200 lakes in the government, the largest, which is called the Solzian Liman or Salt Lagoon, though the water is brackish for an area of nearly three square miles; and next in size is the Temenitza lake near Rostoff. The soil is for the most part very fertile, and agriculture is the principal occupation. Wheat is the staple cereal, and forms an important article of export; but rye, barley, and millet are cultivated for local consumption and distillation. Since about 1850 the culture of flax has attained considerable importance; wild rye-seed is also exported, and in small quantities hemp and the sunflower are grown. The aloe thorn is very abundant, and the fruit is manufactured into a wine called Terevka. The German colonists of Khoritz and Alexandrovia and the Greeks of Marupol cultivate tobacco—the former principally a poor American variety for local consumption, the latter Turkish for export. Potatoes are grown only in gardens, as to plant them in the fields is regarded as prejudicial. Horticulture is poorly developed, but there are beautiful public gardens at Taganrog and Ekaterinodar, the Petrofisky park in the former city being also the oldest in the government. About 7,200,000 acres, or 46 per cent. of the territory of the government, is devoted to pasturage, and in 1861 there were 2,670,000 sheep, 730,000 neat, 200,000 horses. Only about two per cent. of the surface is occupied by wood, and even that is almost exclusively confined to the river courses, especially of the Samara and the Donetz. The trees are almost exclusively deciduous, oak being dominating, and elm, larch, black poplar, poplar, and aspen occurring.

VII. — 100
In 1860 the total population was 1,138,749, and in 1897, 1,281,482. At the former date there were about 26,000 Greeks, more than 30,000 Germans, 19,000 Russians, 9,000 Mahometans, 9,000 Davaras and Wallachians, 7,000 Poles, 7,000 Luthe­ranans, 500 Servians, and 500 Gipsies; while the Little Jews and the different sects stood to each other in the ratio of 23 to 17. Upwards of 5500 were Russian dissenters or Easkolins, 20,318 Protestants, and 7049 Catholics. Two cities only, Rostov on Don and Kadikoy, had upwards of 10,000; and several, such as Novorossiokof, Pavlograd, Murapol, and Anzef, had more than 5000.

EKATERINOSLAFF, a town of European Russia, capital of the above government, is situated on the right bank of the Dniester, at a height of 210 feet above the sea, 394 miles from St Petersburg and 600 from Moscow, in 49° 21' N. lat. and 34° 4' E. long. If the suburb of Novi Koundak, be included, it extends for upwards of four miles along the river, and its average breadth is about 1/4 miles. The oldest part lies very low, and is consequently much exposed to floods. Contiguous to the town on the north-west is the royal village of Novi Madzin or the New Factories, and in the south-east, Kazanay Madziekova. Only about 200 houses are built of stone. The bishop's palace, eight churches, a Raskolnik place of worship, a syna­agogue and four Jewish oratories, a gymnasium, a library, and several benevolent institutions, make up the list of the public buildings. The house now occupied by the Noble's Club was formerly occupied by Potemkin. Among the industrial establishments are brickworks, foundries, flour-mills, and numerous tallow-boilers and soap-works. The general trade is rather restricted by the position of the town above the rapid streams of the Dniester; but there is a very thick trade in wood. Three yearly markets are held, at the largest of which the movement amounts to upwards of 2,500,000 roubles. Population in 1861, 18,881, of whom 3472 were Jews; in 1871, 24,267.

On the site of the town of Ekaterrinoslaff there formerly stood the Polish castle of Koundak, built in 1635 by the French general Baudel. The Cossacks, having destroyed the castle, founded the villages of Old and New Koundak and Polvitsa. In 1765, the town was established by Potemkin, and in the following year the empress, Cathalina II., with her own hand laid the foundation stone of the Cathedral of the Transfiguration. The scheme of Potemkin for the extension of the city were neglected after his death, and Paul I. changed the very name into Novo Rosslesk. The original name was restored in 1809, and the city raised to its present rank in 1830. The cathedral was built on the site originally proposed, but according to a less extensive scale.

EKHMIN, or ARKHMIN, a town of Upper Egypt, a short distance from the right bank of the Nile, between two and three miles above Suheig. It is a place of about 3000 or 4000 inhabitants, has several mosques and two Coptic churches, maintains a weekly market, and manufactures shaws and checked cotton. Outside of the walls are the ruins of two ancient temples, one of which, identified by an inscription of the 12th year of the emperor Trajan as that of Pan, was regarded by Abulfeda as among the most important in Egypt.

Ekhmin, in Coptic Ekhnin or Shmin, is the ancient Chemmis or Panopolis, chief town of the Chemmis nome in the Thebais, and, according to Strabo, inhabited by skullful stone-cutters and huntmen. Ekhnin is one of the oldest cities in the country. Herodotus particularly mentions a temple of Perseus, and asserts that the inhabitants celebrated gymnastic games in honor of this hero; but it has not been ascertained to which of the Egyptians this account should be assigned. Panopolis, or Ekhmin, his probably decayed with the rise of Thebes, and long after it suffered greatly at the hands of the Arab invaders. At the time of Aume-Poocke's visit in 1738, it was still the seat of a powerful em­peror, who extended his protection to the Coptic Catholics, but the dynasty of which he was the last representative, having been transferred before its restoration to the Jesuites, its maintenance of a sanctuary to Beelzebub is mentioned in 2 Kings i. At the time of the Crusades it was still a large village; but now, according to Porter, it contains only 50 mud houses, and has no visible remains of antiquity except two finely built walls.

ELAGABALUS. See HELIOGABALUS.

ELAM. This is the name given in Scripture to the province of Peressa called Susiana by the classical geographers, from Sus or Shushan its capital. In one passage, however (Ezra iv. 9), it is confined to Elamis, the north-western part of the province, and its inhabitants distinguished from those of Shushan, which elsewhere (Dan. viii. 2) is placed in Elam. Strabo (vi. 3, 12, &c.) makes Susiana a part of Persia proper, but a comparison of his account with those of Ptolemy (vi. 3, 1, &c.) and other writers would limit it to the mountainous district to the east of Babylonia, lying between the Oritoas and Tigris, and stretching from India to the Persian Gulf. Along with this mountainous district went a fertile low tract of country on the western side, which also included the marshes at the mouths of the Euphrates and Tigris and the north-eastern coast land of the Gulf. This low tract, though producing large quantities of grain, was intensely hot in summer; the high regions, however, were cool and well watered. The whole country was occupied by a variety of tribes, all speaking agglutinative dialects allied to each other and to the so-called Accadian language of primitive Chaldeans, but in very different stages of civilization. The most important of the tribes were the natives of southern Susiana, called Anzan in the cuneiform inscriptions, who established their capital at Sus, and founded a powerful monarchy there at a very early date. Strabo (xi. 13, 3, 6), quoting from Nearchus, seems to include them under the Elamians, whom be associates with the Uxii, and places on the frontiers of Persia and Susa; but Pliny more correctly makes the Euxine the boundary between Susiana and Elam (N. H., vi. 31), as the Uxii are described as a robber tribe in the mountains adjacent to Media, and their name is apparently to be identified with the title given to the whole of Susiana in the Persian cuneiform inscriptions, Uxii, or “Aborigines.” Uwas the probably the origin of the modern Khuzistan, though Mordtmann would derive the latter from خیث “a sugar-reed.” Immediately bordering on the Persians were the Amardians or Mardians, in whom we may see the Aparashuntiches and Aparasities of Ezra iv. 9, as well as Khappiri or Khalpiri, the name given to Susiana in the Protomadic cuneiform texts, which are written in the agglutinative dialect of the Turanian Medes and northern Elamites. Khappiri appears as Apir in the inscriptions of Mal-Amir. Passing over the Mesababa, which inhabited a valley which may perhaps be the modern Mah-Sabadan, as well as the level district of Yamutbal and Yabtur (with its capital Duran or Deri) which separated Elam from Babylonia, and the smaller districts of the Arman, Cambodene, Chorian, and Getu, and their traditions and sepulchres behind. Nonnes, the Greek poet, was born at Chemmis in 410, and Nersonas died and were buried there about 447.

EKRON, in the Septuagint and Apocrypha Acrecor (Jerusalem), a royal city of the Philistines, identified with the modern Syrian village of Akir, five miles from Ramleh, on the southern slopes of a low ridge separating the plain of Philistia from Sharon. Though included by the Israelites within the limits of the tribe of Judah, and mentioned in Judges xix. as one of the cities of Dan, it was in Philistine possession in the days of Samuel, and apparently maintained its independence. According to the narrative of the Hebrew text, here differing from the Septuagint and Josephus, it was the last town to which the ark was transferred before its restoration to the Israelites. Its maintenance of a sanctuary to Beelzebub is mentioned in 2 Kings i.
important were they, that the whole of Susiana was sometimes called Cisnia after them as by Herodotus (iii. 91; v. 49, etc.). In fact, Susiana was only a late name for the country, dating from the time when Susa had been made a capital of the Persian empire. The Accadian name was Numa, "the highlands" (compare the Vogul name "high"), or Subarti, with the same meaning, and of this the Semitic Elamus (from ἐλαμ) was only a transliteration. Such was also the signification of the native Khapir or Aspir, also writing Khurb, which is synonymous with Subarti (comp. Eber, Gen. xi. 14). The Assyrian inscriptions have disposed of the suggestion, first made by J. Muller and Lassen, that Elam was a corrupt form of the Indo-European Airyama.

The principal mountains of Elam were on the north, called Charbanus and Cambalhus by Pline (vi. 27, 31), and belonging to the Parachotas chain. In the inscriptions they have the general name of "mountains of the east," which extended into Media, where "the mountain of Nize," or "the mountain of the world," the present mountain of ard, was believed to be the spot on which the ark had rested, and the cradle of mankind. There were numerous rivers flowing into either the Tagrus or the Persian Gulf. The most important were the Ulai or Elaeus (Kūran) with its tributary the Panitgiris, the Choaspe (Kerkhah), the Cappadus (River of Dua called Hute in the inscriptions), the Hedypus or Hedypnus (Jervul), and the Orotas (Hwylgan), besides the monumental Surappa and Uvki, or "white river," perhaps to be identified with the Hedyphon and Orotas, which fell into the sea in the neighbourhood of the Caldat of Bit-Yagina, of Khindar, and of the Gambulat, in the marshy region at the mouth of the river. Shushan or Susana (see "Shapur") of the capital, now marked by the mounds of Shush, stood near the junction of the Choaspes and Elaeus (see Susa); and Badada, Madaktu in the inscriptions, lay between the Shapur and the river of Dua. Among the other chief cities mentioned in the inscriptions, may be named Naditu, Khalitemas, Dim-sar, Babulu, Bit-imbi, Khalidu, and Nagutu on the sea coast. Here, in fact, lay some of the oldest and wealthiest towns, the sites of which have, however, been removed inland by the silting up of the shore. The monumental Dilvan, for instance, which according to Sargon was an island 90 ells from the land, is now probably represented by Buuder Dilvan.

The civilization of southern Elam was of very great antiquity. The Accadian or "Highlanders," who inhabited the south, possessed the cities and countries descending from its mountains, carrying with them the picture-writing which afterwards developed into the cuneiform syllabary. An examination of the animals with which they were acquainted was the sea, the ox, the sheep, the gazelle, the bear, the wild bull, the dove, the snake, the fly, the flea, the moth, the bee, and different species of fish, horses, called the "animals of the east," being a subsequent importation. Neither the palm nor the vine were known before their immigration into Babylon, indeed, Strabo states that the vine was first introduced into Susana under the Macedonians. The different tribes of the country were constantly invading Babylon, and from time to time imposed their domain upon it. About 2800 B.C. (according to the date furnished by Assur-bani-pal), the Elamite king Cudur-nankhundi carried away the mannasehs, etc., of the land, which lasted for two generations, his son Run-Agin or En-Aca (Arach) of Larsa being afterwards conquered by Khannun. Cudur was the son of dllamashu, who is identified with the "first Hurrian from Ushumana, who first established Babylon at a very early period of its history, and one of its kings, Aga-kak-nim, had restored the great temple of Bel at Babylon. The whole race represented for the overthrow of the second Cassite dynasty, Elamites from time to time appear as kings of Babylon, and about 1200 B.C. the whole country was ravaged and desolated by the Elamite chieftains. Revenge for this, however, was shortly afterwards taken by the Babylonian Nebuchadnezzar Subsequently, we find Elam and Babylon in alliance against the Medes, and the Assyrians, and in the 5th and 6th centuries B.C., when Babylon was alternately under the sway of the Assyrian princes and of Chaldea and other adversaries, Elam played a large part in its political history. Tuglath-Phileser II., in 740 B.C., first overran the sea-coast as far as the Ulai and Khumba, and in 721 Sargon met Khumbu at the battle of Dura, and drove him across the Assyrian frontier. After the overthrow of Babylon by the Assyrian empire in the west and north, the reduction of Babylonians to a dependent province became a necessity, and this involved the weakening and final conquest of the powerful kingdom of Elam, when itself. The struggle lasted through the reigns of four Assyrian kings, Sargon, Sennacherib, Esarhaddon, and Assur-bani-pal, and the overthrow of Elam was eventually effected by the help of a Medes, and eastward the Medes and Elamites were reduced to vassals. The language of the Hebrew prophets seems to have been allied. In fact, the late period Babyloman to a dependent province became a necessity, and this involved the weakening and final conquest of the powerful kingdom of Elam, when itself. The struggle lasted through the reigns of four Assyrian kings, Sargon, Sennacherib, Esarhaddon, and Assur-bani-pal, and the overthrow of Elam was eventually effected by the help of a Medes, and eastward the Medes and Elamites were reduced to vassals. The language of the Hebrew prophets seems to have been allied.
ELAND (Boedaphus orca) is the largest and most valuable member of the antelope family. It is fully equal to the horse in size, standing six feet high at the shoulders, and measuring nine feet from the nose to the root of the tail. In robustness of build it resembles the ox, and forms the type of the bovine subdivision of antelopes. Its neck is thick, and is furnished with a prominent dewlap, fringed with long hair. Except on the ridge of the back the fur is short, and is usually of a reddish fawn colour above, and white beneath. Its horns are about 20 inches in length, nearly straight, and in the male are surrounded throughout the greater part of their length with a spiral writh; in the female they are more slender, and the spiral ridge is indistinct or absent. The eland is a native of South Africa, where it roams in considerable herds over the open plains, and is usually found in the isolated groves of Acacia capensis, which, like islands in the ocean, are scattered over many of the stony and gravelly plains of the interior. It is slow in its movements as compared with the other antelopes, and is readily captured, while in disposition it is exceedingly gentle, and thus seems eminently adapted for domestication. It breeds readily in confinement, and herds of elands have already been introduced into various parks in Britain. Its flesh is highly prized as an article of food, resembling beef, it is said, in grain and colour, but being more delicate and better flavoured. The eland is remarkable for the quantity of animal food which, it is said, in grain and colour, but being more delicate and better flavoured. The eland was formerly abundant in the stony and gravelly plains of the interior.

... ELASTICITY...
4. The elasticity of shape of many solids is not perfect: it is not known whether it is perfect for any. It might be expected to be perfect for glass and rock crystal and diamond and other hard, brittle, homogeneous substances; but experiment proves that at all events for glass it is not so, and shows on the contrary a notable degree of imperfection in the torsional elasticity of glass fibres. It might be expected that in copper and soft iron and other plastic metals the elasticity of shape would be very imperfect; experiment shows, on the contrary, that in copper, brass, soft iron, steel, platinum, provided the distortion does not exceed a certain limit in each case, elasticity of shape is remarkably perfect, much more perfect than in glass. It is quite probable that even in the softer metals—zinc, tin, lead, cadmium, potassium, sodium, &c.—the elasticity of shape may be as perfect as in the metals mentioned above, but within narrower limits as to degree of distortion. Accurate experiment is utterly wanting; to discover what is the degree of imperfection, if any, of the elasticity of any metal or alloy, when tested within sufficiently narrow limits of distortion.

5. The "viscosity of metals" described below (sections 21–25) does not demonstrate any imperfectness of elasticity according to the definition of section 1, which is purely statistical. The viscosity of solids may (for all we yet know by means of experiment) depend upon a viscosity of fluids, upon a resistance varying with the velocity of the change, and vanishing when the velocity of the change is zero; that is to say, when the body is at rest in any configuration; if so, the elasticity of the substance concerned is perfect within the limits of the experiment in question. If, on the other hand (as the discovery of elastic fatigue described below seems to indicate may be to some degree the case), the loss of energy from the vibrations in the experiments described is due to a dependence of the elastic resilient force upon previous conditions of the substance in respect to strain, the "viscosity" would be continuous with a true imperfectness of strain elasticity. Here, then, we have a definite question which can be answered by experiment only:—Consider a certain definite stress applied to a solid substance, as, for example, a certain "couple" twisting a wire or rod; or a certain weight pulling it out, or compressing it lengthwise; or a certain weight placed on the middle of a beam supported by trebles under its ends. Let it be applied and removed a great many times, and suppose it to be seen that after each application and removal of the stress the body comes to rest in exactly the same configuration as after the previous application or removal of the stress. If now the body be left to itself with the stress removed, and if it be found to remain at rest in the same configuration for minutes, or hours, or days, or years after the removal of the stress, a part of the definition of perfect elasticity is fulfilled. Or, again, if the stress be applied, and kept applied with absolute constancy, and if the body remain permanently in a constant configuration, another item of the definition of perfect elasticity is proved. When any such experiment is made on any metal, unless some of the softer metals (section 4) is to be excepted, there is certainly very little if any change of configuration in the circumstances now supposed. The writer believes, indeed, that nothing of the kind has hitherto been discovered by experiment, provided the stress has been considerably less than that which would break or give a notable permanent twist, or elongation, or bend, to the body, that is to say, provided the distortion has been kept below any of the limits of the body's elasticity as commonly understood (sections 7–20). Mr J. T. Bottomley, with the assistance of a grant of money from the British Association, has commenced making arrangements for secular experiments on the elasticity of metals, in the tower of the university of Glasgow, to answer this question in respect to permanence or non-permanence through minutes, or hours, or days, or years, or centuries. If several gold wires are hung side by side, one of them bearing the smallest weight that will keep it approximately straight, another wire $\frac{1}{2}$ of the breaking weight, another wire $\frac{1}{5}$ of the breaking weight, and so on; the one of them bearing $\frac{1}{2}$ of the breaking weight will probably, in the course of a few hours or days, show very sensible elongation. Will it go on becoming longer and longer till it breaks, or will the time-curve of its elongation be asymptotic? Even with considerably less than $\frac{1}{2}$ of the breaking weight there will probably be a continually augmenting elongation, but with asymptotic time-curve indicating a limit beyond which the elongation never goes, but which it infinitely nearly reaches in an infinite time. It is not probable that a gold wire stretched by $\frac{1}{5}$ of its present breaking weight, or by $\frac{1}{4}$ of its present breaking weight, or even by $\frac{1}{3}$ of its present breaking weight, would break in a thousand or in a million years. The existence of gold ornaments which have been found in ancient tombs and cities, and have preserved their shapes for thousands of years without running down glacier-wise (as does brittle pitch or sealing-wax in the course of a few years in moderately warm climates), seems to prove that for gold (and therefore leaves no doubt also for many other metals) the time-curve is asymptotic, if indeed there is any slow change of shape at all after the application of a moderate stress well within the limits of elasticity. Egyptian and Greek statues, Etruscan vases, Egyptian obelisks, and other stone monuments with their engraved hieroglyphics, flint implements and moulders, and mountains with the geological evidence we have of their antiquity, prove for stones, and pottery, and rocks of various kinds, a permanence for thousands and millions of years of resistance to distorting stress.

6. The complete fulfilment of the definition of perfect elasticity is not proved by mere permanence of the extreme configurations assumed by the substance when a stated amount of the stress is alternately applied and removed. This condition might be fulfilled, and yet the amount of elastic force might be different with the same palpable configuration of the body during gradual augmentation and during gradual diminution of the stress. That it is so in fact is proved by the discovery of viscosity referred to below; but it is not yet proved that if, after increasing the stress to a certain definite amount, the body is brought to rest in the same palpable configuration as before it, the amounts of stress required to hold it in this configuration are different in the two cases. If they are (section 1) the elasticity is imperfect; if they are not the elasticity is perfect within the limits of the experiment (compare section 36 below).

7. LIMITS OF ELASTICITY—Elasticity of Shape.—The degree of distortion within which elasticity of shape is found is essentially limited in every solid. Within sufficiently narrow limits of distortion every solid shows elasticity of shape to some degree—some solids to perfection, so far as we know at present. When the distortion is too great, the body either breaks or receives a permanent bend (that is, such a molecular disturbance that it does not return to its original figure when the bending force is removed). If the first notable deviation from perfectness of elasticity is a breakage, the body is called brittle. A permanent bend, plastic or malleable or ductile. The metals are generally ductile; some metals and metallic alloys and compounds of metals with small proportions of other substances, are brittle; some of them brittle only in certain states of temper, others it seems essentially brittle. The steel of before the days of Bessemer and Siemens is a remarkable instance. When slowly cooled from a bright
ELASTICITY

red heat, it is remarkably tough and ductile. When heated
to redness and cooled suddenly by being plunged in oil or
water or mercury, it becomes exceedingly brittle and hard
(glass-hard, as it is called), and to ordinary observation
seems incapable of taking a permanent bend (though prob-
ably careful observation would prove it not quite so). The
definition of steel used to be approximately pure iron capa-
cible of being tempered glass-hard, the possibility of
brittleness supervening in the course of any treatment
which the metal may meet with, in its manufacture being
an objection against the use of what was formerly called
steel for ship's plates, ribs, strainers, etc., and for many
applications of land engineering, even if the material could
be had in sufficient abundance.

8. Limits of Elasticity (continued)—Elasticity of
Bulk. If we reckon by the amount of pressure, there is
probably no limit to the elasticity of bulk in the direction
of increase of pressure for any solid or fluid; but whether
continued augmentation produces continued diminution of
bulk towards zero without limit, or whether for any or
every solid or fluid there is a limit towards which it must
be reduced in bulk, but smaller than which no degree of
pressure, however great, can condense it, is a question
which cannot be answered in the present state of science.
Would any pressure, however tremendous, give to gold a
density greater than 19-9, or to copper a density greater
than 9-6, after the pressure is removed (section 3 above)?
But whether the body be fluid or a continuous non-
porous solid, it probably recovers the same density, how-
ever tremendously it may have been pressed, and probably
shows perfect elasticity of bulk (section 3 above) through
the whole range of positive pressure from zero to infinity.
Provided the pressure has been equal in all directions like
fluid pressure. As for negative pressure, we have no knowl-
edge of what limit, if any, there may be to the amount of
force which can be applied to a body pulling its surface
equal in all directions. The question of how to apply
the negative pressure is incomparably involved with that of
the body's power to resist. The upper part of the mercury
of a barometer adhering to the glass above the level cor-
responding to the atmospheric pressure is a familiar example
of what is called negative pressure in liquids. Water and
other transparent liquids show similar phenomena, another
of which is the warning of water above its boiling point
in an open glass or metal vessel varnished with shellac.
Attempts to produce great degrees of this so-called negative
pressure are baffled by what seems an instability of the
equilibrium which supervenes when the negative pressure
is too much augmented. It is a very interesting subject for
experimental inquiry to find how high mercury or water or
any other liquid can be got to stand above the level cor-
responding to the atmospheric pressure in a tall hermetically
sealed tube, and how many degrees a liquid can, with all
precautions, be warmed above its boiling point. In each case
it seems to be by a minute bubble forming and expanding
somewhere at the boundary of the liquid, where it is in
contact with the containing vessel, that the possible range
of the negative pressure is limited, judging from what we
see when we carefully examine a transparent liquid, or the
surface of separation between mercury and glass, in any
such experiment. The contrast of the amounts of the
negative pressure practically obtainable or obtained
lithester in such experiments on liquids (which are at the
most those corresponding to the weight of a few metres of
the substance), with that obtainable in the case of even the
weakest solids, is remarkable; and as for the strongest,
consider for instance (sec. 23 below) 17 nautical miles of
steel pianoforte wire hanging by one end. When a cord,
or rod, or wire of any substance hangs vertically,
the negative pressure (for example, 23,000 atmospheres in
the case just cited) in any transverse section is equal to
the weight of the part hanging below it. It is an interest-
ing question not to be answered by any experiment easily
made or even devised,—how much would the longitudinal pull
which can be applied to a cord, rod, or wire without break-
ing it be augmented (probably augmented, but possibly
diminished) by lateral pull applied all round the sides so as
to give equal negative pressure in all directions?

9. Limits of Elasticity (continued)—Elasticity of
Shape for Distortions not Uniform Through the Sub-
stance, and for Compound Distortions; and Elasticity cor-
responding to Co-existent Distortions and Change of Bulk:

Example 1.—A round wire twisted, or a cylindrical shaft trans-
mitting revolution motive in machinery, presents, as we shall see
(sec. 64), an instance of sample distortion, but to different degrees
in different parts of the substance, increasing from the axis where
it is zero, uniformly to the surface where it is greatest.

Example 2.—Elongation of a wire or rod by direct pull, is
(sec. 23) an instance of a compound distortion co-existing with
a radiation of the substance, both distortion and radiation uniform
throughout.

Example 3.—Shortening of a column by end pressure is an in-
stance of a similar compound distortion, but to different degrees
in different parts of the substance, increasing from the axis
where it is zero, uniformly to the surface where it is greatest.

Example 4.—Flexure of a round wire or of a bar, or beam,
or girder, of any shape of normal section, by opposite bending couple
applied at the two ends, is an instance in which one-half of the
substance is stretched, and the other half shortened with exactly the
same combination of distortions and changes of bulk as in examples
2 and 3. The strain is uniform along the length of the bar, but
varies in the cross section in simple ratio to the variation of the
same line (sec. 63) through the centre of gravity of the sectional
area, which, in the case of a round bar, is the diameter perpendicular
to the plane of curvature.

The limits of elasticity in the cases of these four examples
are subjects of vital importance in practical mechanics,
and a vast amount of careful and accurate observation and
experiment, which has given much valuable practical
information regarding them, has been gone through by
engineers, in their necessary dealings with questions regard-
ing strength of materials. Still there is great want of
definite scientific information on the subject of limits of
elasticity generally, and particularly on many elementary
questions (section 21 below), which force themselves
upon us when we endeavour to analyse the molecular
actions concerned in such cases as the four examples
before us. Some principles of much importance for guidance
in practical as well as theoretical deductions from observa-
tions and experiments on this subject were set forth twenty-
ine years ago by Professor James Thomson, in an article
published in the Cambridge and Dublin Mathematical
Journal for November 1848. Nothing is to be gained
either in clearness or brevity by any other way of dealing
with it than reproducing it in extenso. It is accordingly
given here, with a few changes made in it with its author's
concurrence.

It constitutes the following sections, 10—20.

"On the strength of materials, as influenced by the existence or
non-existence of certain mutual strains" among the particles com-
mposing them. By James Thomson, M.A., College, Glasgow.

10. "My principal object in the following paper is to show that the
absolute strength of any material composed of a substance posses-
sing ductility (and few substances, if any, are entirely devoid
of the property) may vary to a great extent, according to the
state of tension or relaxation, in which the particles have been made
to exist when the material as a whole is subject to no external strain.

11. "Let, for instance, a round bar of malleable iron, or a piece
of iron rod, be made red hot, and then be allowed to cool. Its

[Note added Nov. 1877.] More nearly what is now called stress than what is
now called strain is meant by "mutual strain" in this article, which was written in
1848 in connexion with the introduction of the word strain and the distinct definition of the word
strain (see chap. 1 of Mathematical Theory below).
ELASTICITY

particles may now be regarded as being completely relaxed. Let, next, one end of the bar be fixed, and the other be made to receive particles at the circumference of the bar are strained to the utmost extent of which they can admit, without undergoing a permanent alteration in their mutual connection. By the arrangement of the elements of the cross section of the bar afford resistances proportional to the distances of the elements from the centre of the bar; since the particles are displaced in the same direction, the circumstances will be such as to make the distances proportional to the distances of the particles from the centre. The couple which the bar now resists, and which is equal to the sum of the couples due to the resistances of all the elements of the section, is that which is commonly assumed as the measure of the torsional strength of the bar. For future reference, this couple may be denoted by $\tau$, and the angle through which it has twisted the loose end of the bar by $\theta$.

12. The twisting of the bar may, however, be carried still farther, and during the progress of this process the outer particles will yield in virtue of their ductility, those towards the interior subsequently reaching their elastic limits, until, when the twisting has been sufficiently continued, all the particles in the section, except those quite close to the centre, have been strained beyond their elastic limits. Hence, if we suppose $^1$ that no change in the hardness of the substance composing the material has resulted from the sliding of its particles past one another, and that therefore all small elements of the section of the bar afford the same resistance, no matter what their distances from the centre may be, it is easy to prove that the total torsional resistance of the bar is of what it was in its former state; or, according to the notation already adopted, it is $^\pi \tau L$.

13. If, after this, all external stress be removed from the bar, it will assume a new position of equilibrium in which the outer radius will be strained in the direction opposite to that in which it was twisted, and the inner ones in the same direction as that of the twisting, the two sets of opposite couples thus produced among the particles of the bar balancing one another. It is easy to show that the line of separation between the particles strained in one direction and those in the other is a circle whose radius is $\theta$ of the radius of the bar. The particles in this line are evidently subject to no strain $^4$ when no external couple is applied. The bar

...with its new molecular arrangement may now be subjected, as often as we please, to the couple $\pi L$ without undergoing any further alteration. Its strength to resist torsion, in the direction of the length of the couple $L$ has therefore been determined. Its strength to resist torsion in the opposite direction has, however, by the same process, been much diminished, for as soon as its free extremity has been made to rotate through an angle of $\theta$ from the position of equilibrium, the particles of the bar are strained beyond their elastic limits, and they will suffer the utmost distortion of which they can admit without undergoing permanent alteration. Now, it is easy to prove that the couple required to produce a certain angle of torsion is the same in both cases, the new state of the bar as in the old. Hence the ultimate strength of the bar when twisted backwards is represented by a couple amounting to $\pi L$. But, as we have seen, it is $\theta L$ when the wire is twisted forwards. This then, is, is that the force in its new state has twice as much strength to resist torsion in one direction as it has to resist it in another.

14. Principles quite similar to the foregoing, are applicable in regard to beams subjected to cross strain. As, however, our chief object at present is to point out the existence of such principles, to elucidate the mode in which they are to be applied, and to show the great practical importance in the determination of the strength of materials, I need not enter fully into their application in the case of cross strain. The investigation in this case closely resembles that in the case of torsion, but is more complicated on account of the different ultimate resistances afforded by any material to compression and to extension, and on account of the nature of the variations in the form of sections of beams which for different purposes it is found advisable to adopt. I shall therefore merely make a few remarks on this subject.

15. If a bent bar of wrought iron or other ductile material be straightened, its particles are strained in a manner in which the outer radius will be strained in the direction opposite to that in which it was twisted, and the inner ones in the same direction as that of the twisting, the two sets of opposite couples thus produced among the particles of the bar balancing one another. It is easy to show that the line of separation between the particles strained in one direction and those in the other is a circle whose radius is $\theta$ of the radius of the bar. The particles in this line are evidently subject to no strain when no external couple is applied. The bar

...with its new molecular arrangement may now be subjected, as often as we please, to the couple $\pi L$ without undergoing any further alteration. Its strength to resist torsion, in the direction of the length of the couple $L$ has therefore been determined. Its strength to resist torsion in the opposite direction has, however, by the same process, been much diminished, for as soon as its free extremity has been made to rotate through an angle of $\theta$ from the position of equilibrium, the particles of the bar are strained beyond their elastic limits, and they will suffer the utmost distortion of which they can admit without undergoing permanent alteration. Now, it is easy to prove that the couple required to produce a certain angle of torsion is the same in both cases, the new state of the bar as in the old. Hence the ultimate strength of the bar when twisted backwards is represented by a couple amounting to $\pi L$. But, as we have seen, it is $\theta L$ when the wire is twisted forwards. This then, is, is that the force in its new state has twice as much strength to resist torsion in one direction as it has to resist it in another.

14. Principles quite similar to the foregoing, are applicable in regard to beams subjected to cross strain. As, however, our chief object at present is to point out the existence of such principles, to elucidate the mode in which they are to be applied, and to show the great practical importance in the determination of the strength of materials, I need not enter fully into their application in the case of cross strain. The investigation in this case closely resembles that in the case of torsion, but is more complicated on account of the different ultimate resistances afforded by any material to compression and to extension, and on account of the nature of the variations in the form of sections of beams which for different purposes it is found advisable to adopt. I shall therefore merely make a few remarks on this subject.

15. If a bent bar of wrought iron or other ductile material be straightened, its particles are strained in a manner in which the outer radius will be strained in the direction opposite to that in which it was twisted, and the inner ones in the same direction as that of the twisting, the two sets of opposite couples thus produced among the particles of the bar balancing one another. It is easy to show that the line of separation between the particles strained in one direction and those in the other is a circle whose radius is $\theta$ of the radius of the bar. The particles in this line are evidently subject to no strain when no external couple is applied. The bar

...with its new molecular arrangement may now be subjected, as often as we please, to the couple $\pi L$ without undergoing any further alteration. Its strength to resist torsion, in the direction of the length of the couple $L$ has therefore been determined. Its strength to resist torsion in the opposite direction has, however, by the same process, been much diminished, for as soon as its free extremity has been made to rotate through an angle of $\theta$ from the position of equilibrium, the particles of the bar are strained beyond their elastic limits, and they will suffer the utmost distortion of which they can admit without undergoing permanent alteration. Now, it is easy to prove that the couple required to produce a certain angle of torsion is the same in both cases, the new state of the bar as in the old. Hence the ultimate strength of the bar when twisted backwards is represented by a couple amounting to $\pi L$. But, as we have seen, it is $\theta L$ when the wire is twisted forwards. This then, is, is that the force in its new state has twice as much strength to resist torsion in one direction as it has to resist it in another.
Elasticity

cause of an important fact observed by Mr Eaton Hodgkinson in his valuable researches in regard to the stress of cast iron (Report of the British Association for 1857, p. 361.) He has shown that, contrary to what had been previously supposed, a strain, however small in comparison to that which would occasion rupture, which is called a set, or permanent change of the beam, or strain, and the beams on which he experimented. Now this is just what should be expected in accordance with the principles which I have brought forward for the explanation of the causes already pointed out, viz., the parts of a beam previously to the application of an external force have been strained to the utmost, when, by the application of any force, however small, they are still further displaced from their positions of rest, and must necessarily undergo a permanent alteration in their connexion with one another, an alteration permitted by the ductility of the material; or, in other words, the beam as a whole must take a set.

18. In accordance with this explanation of the fact observed by Mr Hodgkinson, I do not think we are to conclude with him that 'the utmost of loading bodies within the elastic limit has no foundation in fact.' It appears to me that the defect of elasticity, which he has shown to occur even with very slight strains, exists only when the strain is applied for the first time; or, in other words, that if a beam has already been subjected to a considerable strain, it may again be subjected to any smaller strain in the same direction without its taking a set. It will readily be seen, however, from Mr Hodgkinson's experiments, that the beam 'elastic limit,' as commonly employed, is entirely vague, and must tend to lead to erroneous results.

19. The considerations adduced seem to me to show clearly that there really exist two elastic limits for any material, between which the displacements or deflexions, or what may in general be termed changes of form, must be confined, if we wish to avoid giving the material a set, or, in case of variable strains, if we wish to avoid giving it a continuous succession of sets which would gradually bring about its destruction; and that these two elastic limits are usually attained one on the one side and the other on the opposite side of the position which the material assumes when subjected to an external strain, though they may be both on the same side of this position of relaxation, and that they may therefore with propriety be called the superior and the inferior limits of the material for the particular arrangement which has been given to its particles; that these two limits are fixed for any given material, but that, if the change of form be continued beyond the limits of the two new limits, by means of an alteration in the arrangement of the particles of the material, be given to it in place of those which it previously possessed; and lastly, that the process employed in the manufacture of materials are usually such as to place the two limits in close contiguity with one another.

20. The introduction of new, though necessary, elements into the consideration of the strength of materials may, on the one hand, seem annoying from rendering the investigations more complicated. On the other hand, their introduction will really have the effect of obviating difficulties, by removing erroneous modes of viewing the subject, and preventing contradictory or incongruous results from being obtained. Thus, the alteration of the section in the beam, which, as before stated, is an actual position assumed by each of the two limits are determined by the peculiar strains which are subsequently applied to the material.

21. Passing now to homogeneous material (sec. 38), homogeneously strained (chap. ii, of Math. Theory below), we are met by physical questions of great interest regarding limits of elasticity. Supposing the solid to be homogeneously distorted in any particular way to nearly the limit of its elasticity for this kind of distortion, with the limits be widened or narrowed by the superposition of negative or positive pressure equal in all directions producing a dilatation or a condensation 1. It seems probable that a dilatation would narrow the limits of elasticity, and a condensation widen them. This, however, is a mere guess: experiment alone can answer the question. Taking a somewhat less simple case. A wire is stretched by a weight to nearly its limits of longitudinal elasticity; a couple twisting it is applied to its lower end—will this either cause the weight to run down and give the wire a permanent set, or break it? Probably—yes; but experiment only can decide. The corresponding question with reference to a column loaded with a weight may have the same answer, but not necessarily so. Experiment again in wanting. A wire hanging stretched by a light weight, merely to steady it, is twisted to nearly its limit of torsional elasticity by a couple of given magnitude applied to its lower end: the stretching weight is increased.—Will this cause it to yield to the couple and take a permanent set 1 Probably—yes. (Certainly yes, for steel piano-forte wire experimented on by Mr M'Farlane to answer this question since it was put in type for this edition 2.) If so, the limits of torsional elasticity of a wire bearing a heavy weight are widened by diminishing or taking off the weight; and no doubt it will follow continuously that a column twisted by opposing couples at its two ends will have its limits of torsional elasticity widened by the application of forces to its two ends, pressing them towards one another. Experiments to answer these questions would certainly reward the experimenter with definite and interesting results.

22. Narrowness of Limits of Elasticity—Solids.—The limit of elasticity of metals, stones, crystals, woods, are so narrow that the distance between any two neighbouring points of the substance never alters by more than a small proportion of its own amount without the substance either breaking or experiencing a permanent set, and therefore the angle between two lines meeting in any point of the substance and passing always through the same matter is never altered by more than a very slight difference, as illustrated in the diagram (Fig. 1.)

! For further information regarding Mr Hodgkinson's views and experiments see his 'Remarks on the Sections of the British Association for the years 1852-3' (29 April 1854, p. 86), and a week by him entitled 'Experimental Researches on the Strength and other Physical Qualities of Cast Iron,' on the Royal Institute of Science at the British Association for 1851.

2 Thus if the section of a beam be of such form that strain in either of the sectioning figures, the one rib or the other, as the case may be, being very weak in comparison to the other part of the beam, it may readily occur that the two sections will be strained exactly on the same side of the position assumed by the base when the external force is free of the beam, though it may have been subject to the action of strain and then loaded or unloaded, or employed as to make all its parts exert their utmost forces, and if the beam be not compressed, the particle as it may come to be compressed to the utmost before the load has been entirely removed.
where the continuous lines represent a portion of the unpulled wire, and the dotted lines the same portion of the wire when pulled. The change in each of the angles would be $\frac{1}{\sqrt{\text{rad}}}$ of the radian in virtue of the elongation were there no lateral shrinking, and about $\frac{1}{\sqrt{\text{rad}}}$ of the radian in virtue of the lateral shrinking were there no elongation. The whole change experienced by each of the right angles is therefore actually (section 37) $\frac{1}{\sqrt{\text{rad}}} + \frac{1}{\sqrt{\text{rad}}}$ or about $\frac{1}{\sqrt{\text{rad}}}$ of the radian, or $0.84$. This is an extreme case. In all other cases of metals, stones, glasses, crystals, the substance either breaks or takes a permanent bend, probably before it experiences any very great angular distortion as a degree; and except in the case of steel we may roughly regard the limits of elasticity as being something between $\frac{1}{\sqrt{\text{rad}}}$ and $\frac{1}{\sqrt{\text{rad}}}$ in respect to the linear elongation or contraction, and from $\frac{1}{\sqrt{\text{rad}}}$ of a degree to half a degree in respect to angular distortion.

24. On the other hand, gelatinous substances, such as india-rubber and elastic jellies, have very wide limits of elasticity. A vulcanized india-rubber band, for instance, is capable of being stretched, again and again, to eight times its length, and returning always to nearly its previous condition when the stress is removed. A shape of transparent jelly presents a beautiful instance of great degrees of distortion with seemingly very perfect elasticity. All these instances, india-rubber and jellies, show with great changes of shape but slight changes of bulk. They have, in fact, all, as nearly as experiment has hitherto been able to determine, the same compressibility as water.

25. Cork, another body with very wide limits of elasticity (very imperfect elasticity it is true) is singular, among bodies seeming homogenous to the eye, in its remarkably easy compressibility. It is, in fact, the only seemingly homogenous solid which shows to the unaided eye any sensible change of bulk under any practically applicable forces. A small homogenous piece torn out of a cork may, by merely pressing it between the fingers, be readily compressed to half its bulk, and a large slab of cork in a Branah press may be compressed to $\frac{1}{\sqrt{\text{rad}}}$ of its bulk. An ordinary bottle cork loaded with a small piece of metal presents a very interesting appearance in an Oersted glass compressing vessel; first floating, and when compressed to 20 or 30 atmospheres sinking, and shrivelling in bulk very curiously; then on the pressure being removed, expanding again, but not quite to previous bulk, and floating up or remaining down according to the amount of its load.

The diverseness presented by cork and gelatinous bodies in opposite directions from the regular elasticity of hard solids form an interesting subject, to which we shall return later (section 48).

26. Liquids.—In respect to liquids, there are no limits of elasticity so far as regards the magnitude of the positive pressure applied or conceivably applicable; but in respect to the magnitude of negative pressure, and in respect to the magnitude of the change of bulk, whether by negative or positive pressure, there are probably very decided and not very wide limits. Thus water, though condensed to $\frac{1}{\sqrt{\text{rad}}}$ of its bulk by 2000 atmospheres in Perkins’ experiments corrected roughly for the compressibility of his glass “piezometer,” which is very nearly at the rate of $1.77$ per atmosphere found (section 75) more accurately by subsequent experiments for moderate pressures up to 20 or 30 atmospheres, may be expected to be compressed by much less than $\frac{1}{\sqrt{\text{rad}}}$ of its volume under a pressure of 7000 atmospheres. How much it or any other liquid is condensed by a pressure of 10,000 atmospheres, or by 20,000 atmospheres, is an interesting subject for experimental investigation.

27. Gases.—In respect to rarefaction, and in respect to proportionate condensation, gases present enormously wider limits of elasticity than any liquids or solids,—in fact no limit in respect to dilatation, and in respect to condensation a definite limit only when the gas is below Andrew’s “critical temperature.” If the gas be kept at any temperature above that critical temperature, it remains homogeneous, however much it be condensed, and therefore for a fluid above the critical temperature there is, in respect to magnitude of pressure, no superior limit to its elasticity. On the other hand, if a fluid be kept at any constant temperature less than its critical temperature, it remains homogeneous, and presents an increasing pressure until a certain density is reached; when its bulk is further diminished it divides into two parts of less and greater density (the part of less density being called vapour, that of greater density being called liquid, if it is not solid) and presents no further increase of pressure until the vaporous part shrinks to nothing, and the whole becomes liquid (that is to say, homogenous fluid at the greater of the two densities) or else becomes solid—the question whether the more dense part is liquid or solid depending on the particular temperature below the critical temperature at which the whole substance is kept during the supposed experiment.

28. The thermo-dynamic reasoning of Professor James Thomson, which showed the effect of change of pressure in altering the freezing point of a liquid, leads to analogous considerations regarding the effect of continuous increase or decrease of pressure upon a gas consisting of the same substance partly in the liquid and partly in the solid state at one temperature. The three cases of transition from gas to liquid, from gas to solid, and from liquid to solid, present us with perfectly definite limits of elasticity, the only perfectly definite limits of elasticity in nature of which we have any certain knowledge.

29. Viscosity of Fluids and Solids.—Closely connected with limits of elasticity, and with imperfectness of elasticity, is viscosity, that is to say, resistance to change of shape depending on the velocity of the change. The full discovery of the viscosity of liquids and gases is due originally to Stokes; and his hypothesis that in fluids the force of resistance is in simple proportion to the velocity of change of shape has been subsequently confirmed by the experimental investigations of Helmholtz, Maxwell, Meyer, Kundt, and Warburg. The definition of a fluid given in section 2 above may, by section 1, be transformed into the following:—A fluid is a body which requires no force to keep it in any particular shape, or—A fluid is a body which exercises no permanent resistance to a change of shape. The resistance to a change of shape presented by a fluid, evanescent as it is when the shape is not being changed (or vanishing when the velocity of the change vanishes), is essentially different from that permanent resistance to change of shape, the manifestation of which in solids constitutes elasticity of shape as defined in section 1.

Maxwell’s admirable kinetic theory of the viscosity of gases points to a full explanation of viscosity, whether of gases, liquids, or solids, in the consideration of configurations and arrangements of relative motions of molecules, permanent in a solid under distorting stress, temporary in fluids or solids while the shape is being changed, in

1 Transactions of Royal Society, June 1836, “On the Progressive Compression of Water by high degrees of force, with some trials of its effects on other liquids,” by J. Perkins. Communicated by W. H. Woolaston, M. D., V. P. B. S.
ELASTICITY

virtue of which elastic forces in the quiescent solid, and viscous resistance to change of shape in the non-quiescent fluid or solid, are produced.

30. Viscosity of Metals and Fatigue of their Elasticity.—Experimental exercises performed by students in the physical laboratory of the university of Glasgow during the session 1864-65, brought to light some very remarkable and interesting results, proving a loss of energy in elastic vibrators (sometimes as much as two or three per cent. of energy lost in the course of a single vibration in our direction) incomparably greater than anything that could be due to imperfections in their elasticity (section 1), and showing also a very remarkable fatigue of elasticity, according to which a wire which had been kept vibrating for several hours or days through a certain range came to rest much quicker when left to itself than when set in vibration after it had been at rest for several days and then immediately left to itself. Thus it was found that the rates of subsidence of the vibrations of the several wires experimented on were generally much less rapid on the Monday mornings, when they had been at rest since the previous Friday, than on other days of the week, or than after several series of experiments had been made on a Monday. The following statement (sections 31-34) is extracted from a short article by W. Thomson, in the Proceedings of the Royal Society for May 18, 1865, containing some of the results of these observations.

31. „Viscosity. — By induction from a great variety of observed phenomena, we are compelled to conclude that no change of volume or of shape can be produced in any kind of matter without dissipation of energy. Even in dealing with the absolutely perfect elasticity of volume presented by every fluid, and possibly by some solids, as for instance, homogeneous crystals, dissipation of energy is an inevitable result of every change of volume, because of the accompanying change of temperature, and consequent dissipation of heat by conduction or radiation. The same cause gives rise necessarily to some degree of dissipation in connection with every change of shape of an elastic solid. But estimates founded on the thermodynamic theory of elastic solids, which I have given elsewhere,¹ have sufficed to prove that the loss of energy due to this cause is small in comparison with the whole loss of energy observed in many cases of vibration. I have also found, by vibrating a spring alternately in air of ordinary pressure and in the exhausted receiver of an air-pump, that there is an internal resistance to its motions immensely greater than the resistance of the air. The same conclusion is to be drawn from the observation made by Kupffer in his great work on the elasticity of metals, that his vibrating springs subsided much more rapidly in their vibrations than rigid pendulums supported on knife-edges. The subsidence of vibrations is probably more rapid in glass than in some of the most elastic metals, as copper, iron, silver, aluminium;² but it is much more rapid than in glass, marvellously rapid indeed, in some metals (as for instance zinc),³ and in india-rubber, and even in homogenious jellyes.

32. „The fractional resistance against change of shape must in every solid be infinitely small when the change of shape is made at an infinitely slow rate, since, if it were finite for an infinitely slow change of shape, there would be infinite rigidity, which we may be sure¹ does not exist in nature. Hence there is in elastic solids a molecular friction which may be properly called viscosity of solids, because, as being an internal resistance to change of shape depending on the rapidity of the change, it must be classed with fluid molecular friction, which by general consent is called viscosity of fluids. But, at the same time, it ought to be remarked that the word viscosity, as used hitherto by the best writers, when solids or heterogeneous semi-solid semi-fluid masses are referred to, has not been distinctly applied to molecular friction, especially not to the molecular friction of a highly elastic solid within its limits of high elasticity, but has rather been employed to designate a property of slow continual yielding through very great, or altogether unlimited, extent of change of shape, under the action of continued stress. It is in this sense that Forbes, for instance, has used the word in stating that † viscous theory of glacial motion,' which he demonstrated by his grand observations on glaciers. As, however, he and many other writers after him have used the words plasticity and plastic, both with reference to homogeneous solids (such as wax or pitch even though at brittle, soft metals, &c.) and to heterogeneous semi-solid semi-fluid masses (as mud, moist earth, mortar, glacial ice, &c.), to designate the property common to all cases of experiencing, under continued stress, either quite continued and unlimited change of shape, or gradually very great change at a diminishing (asymptotic) rate through infinite time, and as the use of the term plasticity implies no more than does viscosity any physical theory or explanation of the property, the word viscosity is without inconvenience left available for the definition I propose.

33. „To investigate the viscosity of metals, I have in the first place taken them in the form of round wires, and have chosen torsional vibrations, after the manner of Coulomb, for observation, as being much the easiest way to arrive at definite results. In every case one end of the wire was attached to a rigid vibrator with sufficient firmness (thorough and smooth soldering I find to be always the best plan when the wire is thick enough); and the other to a fixed rigid body, from which the wire hangs, bearing the vibrator at its lower end. I arranged sets of observations to be made for the separate comparison of the following cases:—

(a) The same wire with different vibrators of equal weights to give equal stretching-tractions but different moments of inertia (to test the relation between viscous resistances against motions with different velocities through the same range and under the same stress).

(b) „The same wire with different vibrators of equal moments of inertia but unequal weights (to test the effect of different longitudinal tractions on the viscous resistance to torsion under circumstances similar in all other respects).

(c) „The same wire and the same vibrator, but different initial ranges in successive experiments (to test an effect unexpectedly discovered, by which the subsidence of vibrations from any amplitude takes place at very different rates according to the immediately previous molecular condition, whether of quiescence or of recurring changes of shape through a wider range).

(d) „Two equal and similar wires, with equal and similar vibrators, one of them kept as continually as possible in a state of vibration, from day to day; the other kept at rest, except when vibrated in an experiment once a day (to test the effect of continued vibration on the viscosity of a metal).

34. „Results.—(a) It was found that the loss of energy in

¹ Those who believe in the existence of indivisible, infinitely strong and infinitely rigid, very small bodies (finite hard atoms!) deny this.

ELASTICITY

a single vibration through one range was greater the greater the velocity (within the limits of the experiments); but the difference between the losses at low and high speeds was much less than it would have been had the resistance been, as Stokes has proved it to be, in fluid friction, approximately as the rapidity of the change of shape.

The irregularities in the results of the experiments which up to this time I have made seem to prove that much smaller vibrations (producing less absolute amounts of distortion in the part of the wires most strained) must be observed before any simple law of relation between molecular friction and velocity can be discovered.

(b) "When the weight was increased, the viscosity was always at first much increased; but then day after day it gradually diminished and became as small in amount as it had been with the lighter weight. It has not yet been practicable to continue the experiments long enough in any case to find the limit to this variation.

(c) "The vibration subsided in aluminium wires much more rapidly from amplitude 20 to amplitude 10, when the initial amplitude was 40, than when it was 20. Thus, with a certain aluminum wire, and vibrator No. 1 (tune of vibration one way 1 757 second), the number of vibrations counted were in three trials—

<table>

<tr>
<th>Subsidence from initial amplitude</th>
<th>Vibration</th>
</tr>
</thead>
<tbody>
<tr>
<td>to 10.</td>
<td>86 94 94</td>
</tr>
<tr>
<td>From 20 (in course of the same experiments)</td>
<td>98 98 98</td>
</tr>
<tr>
<td>No. 1</td>
<td></td>
</tr>
</tbody>
</table>

And the same wire and the vibrator showed—

<table>
<thead>
<tr>
<th>Subsidence from initial amplitude</th>
<th>Vibration</th>
</tr>
</thead>
<tbody>
<tr>
<td>to 10.</td>
<td>96 98 98</td>
</tr>
<tr>
<td>From 20 to 10.</td>
<td>90 90</td>
</tr>
</tbody>
</table>

Again, the same wire, with vibrator No. 2 (tune of vibration one way 1 395), showed, in two trials—

<table>
<thead>
<tr>
<th>Subsidence from initial amplitude</th>
<th>Vibration</th>
</tr>
</thead>
<tbody>
<tr>
<td>to 10.</td>
<td>54 53</td>
</tr>
<tr>
<td>From 20 to 10.</td>
<td></td>
</tr>
</tbody>
</table>

This remarkable result suggested the question (d).

(d) "In a wire which was kept vibrating nearly all day, from day to day, after several days very much molecular friction was found than in another kept quiescent except during each experiment. Thus two equal and similar pieces of copper wire were put up about the 26th of April, hanging with equal and similar lead weights, the upper and lower ends of the two wires being similarly fixed by soldering. No. 2 was more frequently vibrated than No. 1 for a few days at first, but no comparison of velocities was made till May 15. Then No. 1 subsided from initial range to 10 in 97 vibrations. No. 2 gave the same subsidence in 77 vibrations.

During the greater part of May 16 and 17, No. 2 was kept vibrating and No. 1 quiescent, and late on May 17 experiments with the following results were made:—

<table>
<thead>
<tr>
<th>Time per Vibration</th>
</tr>
</thead>
<tbody>
<tr>
<td>No. 1 subsided from 20 to 10 after 99 vibrations in 237 sec.,</td>
</tr>
<tr>

</tr>
</tbody>
</table>

35. The investigation was continued with much smaller degrees of maximum angular distortion, to discover, if possible, the law of the molecular friction, the existence of which was demonstrated by these experiments. Two questions immediately occurred.—What is the law of subsidence of range in any single series of oscillations, the vibrator being undisturbed by external forces (question (a) of § 33 above); what is the relation between the law of subsidence in two sets of oscillations having different periods, with the same elastic body in the same circumstances of elastic force, as for instance the same or similar metallic wires with equal weights hung upon them, performing torsional oscillations in different times on account of the moments of inertia of the suspended masses being different?

36 So far as the irregularities depending on previous conditions of the elastic substance allowed any simple law to be indicated, the experimental answer to the first question for degrees of angular distortion much smaller than the palpable limits of elasticity was the COMPOUND INTEREST LAW, that is to say,—The diminishments of range per equal intervals of time or per equal numbers of oscillations bore a constant proportion to the diminishing range, or, The differences of the logarithms of the ranges were proportional to the intervals of time.

The only approach to an answer to the second question yet obtained is that the proportionate losses of amplitude in the different cases are not such as they would be if the molecular resistance were simply proportional to the velocity of change of shape in the different cases. If the molecular friction followed this simple law, the proportionate diminutions of range per period would be inversely as the periods, or per equal intervals of time they would be inversely as the squares of the periods. Instead of the proportion being so, the loss was greater than the longer periods than that calculated according to the law of square roots from its amount in the shorter periods. It was in fact as it would be if the result were wholly or partially due to imperfect elasticity, or "elastische Nach-wirkung" — elastic after-working — as the Germans call it (compare section 6 above). To form a rough idea of the results, irrespectively of the ultimate molecular theory (which is to be looked for in the proper extension of Maxwell's kinetic theory of viscosity of gases), consider a perfectly elastic vesicular solid, whether like a sponge with communications between the vesicles, or with each vesicle separately inclosed in elastic solid: imagine its pores and interstices filled up with a viscous fluid, such as oil. Statical experiments will show perfect elasticity of bulk and shape; kinetic experiments will show losses of energy such as are really shown by vibrators of india-rubber, jelly, glass, metals, or other elastic homogeneous solids, but more regular, and following more closely the compound interest law for single series and the law of relation to square roots of periods stated above for sets of oscillations in different periods. In short, according to Stokes's law of viscosity of fluids, our supposed vesicular vibrator would follow the law of subsidence of a simple vibrator experiencing a resistance simply proportional to the velocity of its motion, while no such simple law is applicable to the effects of the internal molecular resistance in a vibrating elastic solid.

37. Hooke's Law.—A law expressed by Hooke with Latin terseness in the words Ut tensio sic vis is the foundation of the mathematical theory of the elasticity of hard solids. By tensio here is meant not force (as is generally meant by the English word tension), but an elongation produced by force. In English, then, Hooke's law is that elongation (understood of an elastic solid) is proportional to the force (or tension) acting on it. It is clear, however, to be extended continuously from elongation to contraction in respect to the effect, and from pull to push in respect.
to the cause; and the experiments on which it is founded prove a perfect continuity from the pulling force to a smaller force in the same direction, and from the less force to zero, and from zero of pulling force to different degrees of push or positive pressure, or negative pull. Experimental proof merely of the continuance of the phenomena through zero of force suffices to show that, for infinitely small positive or negative pull, positive or negative elongation is simply proportional to the positive or negative pull; or, in other words, positive or negative contraction is proportional to the positive or negative pressure producing it. But now must be invoked minutely accurate experimental measurement to find how near, as the force, is one proportion of the force, and this through finite ranges of contraction and elongation. The answer happily for mathematicians and engineers is that Hook's law is fulfilled, as accurately as any experiments hitherto made can tell, for all metals and hard solids each through the whole range within its limits of elasticity; and for woods, cork, india-rubber, jellies, when the elongation is not more than two or three per cent., or the angular distortion not more than a few hundredths of the radian (or not more than about two or three degrees). The same law holds for the condensation of liquids up to the highest pressures under which their compressibility has hitherto been accurately measured. [A decided but small deviation from Hooke's law has been found in steel pianoforte wire under combined influence of tension and longitudinal pull by Mr. Farlane in experiments made for the present article after this section was in type. See § 81.] Boyd's law of the "spring of air" shows that the augmentation of density of a gas is simply proportional to the augmentation of the pressure, through the very wide ranges of pressure through which that law is approximately enough fulfilled. Hence the infinitesimal diminution of volume produced by a given infinitesimal augmentation of pressure varies as the square of the volume, and this proportionate diminution of volume (that is to say, the ratio of the diminution of volume to the volume) is proportional to the volume, or inversely proportional to the density. Andrews's experiments on the compressibility of a fluid, such as carbonic acid, at temperatures slightly above the critical temperature, and of the gas and of liquids at temperatures slightly below the critical temperature, are intensely interesting, not merely in respect to the natural history of elasticity, but as opening vistas into the philosophy of molecular action.

We cannot expect to find any law of simple proportionality between stress and change of dimensions, or proportionate change of dimensions, in the case of any elastic or semi-elastic "soft" solids, such as cork on one hand or india-rubber or jellies on the other, when strained to large angular distortions, or to large proportionate changes of dimensions. The exceedingly imperfect elasticity of all these solids, and the want of definiteness of the substances of many of them, renders accurate experimenting unavailing for obtaining any very definite or consistent numerical results; but it is interesting to observe roughly the forces required to produce some of the great strains of which they are capable without any total break down of elastic quality; for instance, to hang weights successively on an india-rubber band and measure the elongations. This any one may readily do, and may be surprised to find the enormous increase of resistance to elongation presented by the attenuated band before it breaks.

38. Homogeneity Defined.—A body is called homogeneous when any two equal, similar parts of it, with corresponding lines parallel and turned towards the same parts, are undistinguishable from one another by any difference in quality. The perfect fulfilment of this condition, without any limit as to the smallness of the parts, though conceivable, is not generally regarded as probable, for any of the real solids or fluids known to us, however seemingly homogeneous. It is held by all naturalists that there is a molecular structure, according to which, in compound bodies such as water, ice, rock-crystal, &c., the constituent substances lie side by side, or arranged in groups of finite dimensions, and form in bodies called simple (that is those not known to be chemically resolvable into other substances) there is no ultimate homogeneity. In other words, the prevailing belief is that every kind of matter with which we are acquainted has a more or less coarse-grained texture, whether (as great masses of solid brick-work or stonework, or as natural sandstones or granite rocks) having visible molecules, or (as seemingly homogeneous metals, or continuous crystals, or liquids, or gases) having molecules too small to be directly visible, or measurable but not discoverably small,—really, it is to be believed, of dimensions to be accurately determined in future advances of science. Practically the definition of homogeneity may be applied on a very large scale to masses of building or coarse-grained conglomerate rock, or on a more moderate scale to blocks of common sandstone, or on a very small scale to seemingly homogeneous metals; on a scale of extremely undiscovered fineness, to vitreous bodies, continuous crystals, solidified gums, as india-rubber, gum-arabic, &c., and fluids.

39. Isotropic and Anisotropic Substances Defined.—The substance of a homogeneous solid is called isotropic when a spherical portion of it, tested by any physical agency, exhibits no difference in quality however it is turned, which amounts to the same, a cubical portion, cut from any position in an isotropic body, exhibits the same qualities relatively to each pair of parallel faces. Or two equal and similar portions cut from any positions in the body, not subject to the condition of parallellism (section 38), are undistinguishable from each other. A substance which is not isotropic, but exhibits differences of quality in different directions, is called anisotropic. The remarks of section 38 relative to homogeneity in the aggregate, and the supposed ultimately heterogeneous texture of all substances, however seemingly homogeneous, indicate corresponding limitations and non-rigorous practical interpretations of isotropy and anisotropy.

40. Isotropy and Anisotropy of Different Sets of Properties.—The substance of a homogeneous solid may be isotropic in one quality or class of qualities, but anisotropic in others. Or a transparent substance may transmit light at different velocities in different directions through it (that is, be doubly-refracting), and yet a cube of it may (and does in many natural crystals) show no sensible difference in its absorption of white light transmitted across it perpendicularly to any of its three pairs of faces. Or (as a crystal which exhibits dichroism) it may be sensibly anisotropic relatively to the absorption of light, but not sensibly doubly-refracting, or it may be dichroic and double-refracting, and yet it may conduct heat equally in all directions. Still, as a rule, a homogeneous substance which is anisotropic for one quality must be more than infinitesimally anisotropic for every quality which has directional character adorning of a corresponding anisotropy.

41. Moduli of Elasticity.—A modulus of elasticity is the number obtained by dividing the number expressing a stress by the number expressing the strain which it produces. A modulus is called a principal modulus when
the stress is such that it produces a strain of its own type.

(1) An isotropic solid has two principal moduluses—a modulus of compression and a rigidity.

(2) A crystal of the cube class (fluor-spar, for instance) has three principal moduluses—one modulus of compression and two rigidities.

(3) An anisotropic solid having (what no natural crystal has, but what a drawn wire has) perfect isotropy of physical qualities relative to all lines perpendicular to a certain axis of its substance has three principal moduluses, two determinable from its different compressibilities along and perpendicular to the axis, or from one compressibility and the "Young's modulus" (section 42) of an axial bar of the substance, or determinable from two compressibilities; and one rigidity determinable by measurement of the torsional rigidity of a round axial bar of the substance.

(4) A crystal of Iceland spar has four principal moduluses, three like those of case (3), and another rigidity depending on (want of complete circular symmetry, and possession of triaxial symmetry of form, involving sextuple elastic symmetry, round the crystalline axis.

(5) A crystal of the rectangular parallelepiped (or "teessarid") class has six distinct principal moduluses which, when the directions of the principal axes are known, are determinable by six single observations,—three of the three (generally unequal) compressibilities along the three axes; and three of the three rigidities (no doubt generally unequal) relatively to the three simple distortions of the parallelepipeds, in any one of which one pair of parallel rectangular faces of the parallelepiped become oblique parallelograms.

(6) An anisotropic solid generally has six principal moduluses, which, when a piece of the solid is presented without information, and without any sure indication from its appearance of any particular axis or axes of symmetry of any kind, require just twenty-one independent observations for the determination of the fifteen quantities specifying their types, and the six numerical values of the moduluses themselves.

42. "Young's Modulus," or Modulus of Simple Longitudinal Stress.—Thomas Young called the modulus of elasticity of an elastic solid the amount of the end-pull or end-thrust required to produce any infinitesimal elongation or contraction of a wire, or bar, or column of the substance multiplied by the ratio of its length to the elongation or contraction. In this definition the definite article is clearly missing. There are, as we have seen, two moduluses of elasticity for an isotropic solid,—one measuring elasticity of bulk, the other measuring elasticity of shape. An interesting and instructive illustration of the confusion of ideas so often rising in physical science from faulty logic is to be found in an Account of an Experiment on the Elasticity of Ice: By Benjamin Bevan, Esq., in a letter to Dr Thomas Young, Foreign Sec. R. S.," and in Young's "Note" upon it, both published in the Transactions of the Royal Society for 1826. Bevan gives an interesting account of a well-designed and well-executed experiment on the flexure of a bar, 3.97 inches thick, 10 inches broad, and 100 inches long, of ice on a pond near Leighton Buzzard (the bar remaining attached by one end to the rest of the ice, but being cut free by a saw along its sides and across its other end), by which he obtained a fairly accurate determination of "the modulus of ice," and says that he repeated the experiment in various ways on ice bars of various dimensions, some remaining attached by

one end, others completely detached, and found results agreeing with the first as nearly as "the admission of the thickness could be ascertained." He then proceeds to compare "the modulus of ice" which he had thus found with "the modulus of water," which he quotes from Young's Lectures as deduced from Canton's experiments on the compressibility of water. Young in his "Note" does not point out that the two moduluses were essentially different, and that the modulus of his definition, the modulus determinable from the flexure of a bar, is essentially zero for every fluid. We now call "Young's modulus" the particular modulus of elasticity defined as above by Young, and so avoid all confusion.

43. Modulus of Rigidity.—The "modulus of rigidity" of an isotropic solid is the amount of tangential stress divided by the deformation it produces,—the former being measured in units of force per unit of the area to which it is applied in the manner indicated by the annexed diagram (fig. 3), and the latter by the variation of each of the four right angles reckoned in fraction of the radian. By drawing either diagonal of the square in the diagram we see that the deforming stress represented by it gives rise to a normal traction on every surface of the substance perpendicular to the square and parallel to one of its diagonals, and an equal normal pressure on every surface of the solid perpendicular to the square and parallel to the other diagonal, and that the amount of each of these normal forces per unit of area is equal to the amount per unit area of the tangential forces which the diagram indicates. The corresponding geometrical proposition, also easily proved, is as follows: A strain compounded of a sample extension in one set of parallels, and a sample contraction of equal amount in any other set perpendicular to those, is the same as a simple shear in either of the two sets of planes cutting the two sets of parallels at 45°, and the numerical measuring of this shear or simple distortion is equal to double the amount of the elongation or contraction, each reckoned per unit of length.

Hence we have another definition of "modulus of rigidity" equivalent to the preceding:—The modulus of rigidity of an isotropic substance is the amount of normal traction or pressure per unit of area, divided by twice the amount of elongation in the direction of the traction or contraction in the direction of the pressure, when a piece of the substance is subjected to a stress producing uniform distortion.

44. Conditions fulfilled in Elastic Isotropy.—To be elastically isotropic, a spherical or cubical portion of any solid, if subjected to uniform normal pressure (positive or negative) all round, must, in yielding, experience no deformation, and therefore must be equally compressed (or dilated) in all directions. But, further, a cube cut from any position in it, and acted on by tangential or distorting stress in planes parallel to two pairs of its sides, must experience simple deformation, or "shearing" parallel to either pair of these sides, unaccompanied by condensation or dilatation, 6

6 The directions of these forces are called the "axes" of the stress. The corresponding directions in the corresponding strain are called the "axes of the strain.

6 Mathematical Theory, chap. vi.

7 This, with several of the following sections, 44-51, is borrowed, with but slight change, from the first edition of Thomson and Tait's Natural Philosophy, by permission of the authors.

8 It must be remembered that the changes of figure and volume we are concerned with are so small that the principle of superposition is
and the same in amount for all the three ways in which a stress may be thus applied to any one cube, and for different cubes taken from any different positions in the solid. Hence the elastic quality of a perfectly elastic, homogeneous, isotropic solid is fully defined by two elements,—its resistance to distortion and its resistance to compression. The first has been already considered (section 43). The second is measured by the amount of uniform pressure in all directions per unit area of its surface required to produce a stated very small compression. The numerical reckoning of the first is the compressing pressure divided by the diminution of the bulk of a portion of the substance which, when uncompressed, occupies the unit volume. It is sometimes called the "elasticity of bulk," or sometimes the "modulus of bulk-elasticity," sometimes the "modulus of the longitudinal dilatation," sometimes the "cubic dilatation," and sometimes the "modulus of longitudinal dilatation," each reckoned as usual per unit of linear measure. One specimen of the fallacious mathematics referred to in chap. xvi. of the mathematical theory below is a celebrated conclusion of Navier's and Poisson's that the ratio of lateral contraction to elongation by pull without transverse force is \( \frac{1}{2} \). This would require the rigidity to be \( \frac{1}{2} \) of the resistance to compression, for all solids; which was first shown to be false by Stokes in many obvious observations, proving enormous discrepancies from it in many well-known bodies, and rendering it most improbable that there is any approach to a constancy of ratio between rigidity and resistance to compression in any class of solids. Thus clear elastic jellies and India-rubber present familiar specimens of isotropic homogeneous solids which, while differing very much from one another in rigidity ("stiffness"), are probably all of very nearly the same compressibility as water, which is about \( \frac{1}{6000} \) per atmosphere. Their resistance to compression, measured by the reciprocal of this, is obviously many hundred times the absolute amount of the rigidity of the stiffest of those substances. A column of any of them, therefore, when pressed together or pulled out, within its limits of elasticity, by balancing forces applied to its ends (or an India-rubber band when pulled out), experiences no sensible change of volume, though very sensible change of length. Hence the proportionate extension or contraction of any transverse diameter must be sensibly equal to half the longitudinal contraction or extension; and such substances may be practically regarded as incompressible elastic solids in interpreting all the phenomena for which they are most remarkable. Stokes gave reasons for believing that metals also have in general greater resistance to compression, in proportion to their rigidities, than according to the fallacious theory, although for them the discrepancy is very much less than for the gelatinous bodies. This probable conclusion was soon experimentally demonstrated by Wertheim, who found the ratio of lateral to longitudinal change of lineal dimensions, in columns acted on solely by longitudinal force, to be about \( \frac{1}{2} \) for glass and brass; and by Kirchhoff, who, by a well-devised experimental method, found \( \frac{877}{500} \) as the value of that ratio for brass, and \( \frac{234}{500} \) for iron. For copper it is shown to lie between \( \frac{236}{500} \) and \( \frac{441}{500} \), by experiments quoted below, measuring the torsional and longitudinal rigidities of copper wires.

45. Strains produced by a single Longitudinal Stress (subject of Young's Module.)—Any stress whatever may be made up of simple longitudinal stresses. Hence, to find the relation between any stress and the strain produced by it, we have only to find the strain produced by a simple longitudinal stress, which, for an isotropic solid, we may do at once thus:—A single longitudinal stress \( P \) is equivalent to a uniform dilating tension \( \frac{1}{2} P \) in all directions, compounded with two distorting stresses, each equal to \( \frac{1}{2} P \), and having a common axis in the line of the given longitudinal stress, and their other two axes any two lines at right angles to one another and to it.

The diagram (fig. 4), drawn in a plane through one of the latter lines and the former, sufficiently indicates the synthesis,—the only forces not shown being those perpendicular to its plane.

Hence if \( n \) denote the rigidity, and \( k \) the modulus of compressibility, or the modulus of bulk-elasticity (being the same as the reciprocal of the compressibility), the effect will be an equal dilatation in all directions, amounting, per unit of volume, to

\[
\frac{1}{k}
\]

and having (section 43, footnote) their axes in the directions just stated for the axes of the distorting stresses.

46. The dilatation and shears thus determined may be conveniently reduced to simple longitudinal strains by following the indications of section 43, thus:—The two shears together constitute an elongation amounting to \( \frac{1}{2} P \) in the direction of the given force \( P \), and equal contraction amounting to \( \frac{1}{k} \) in all directions perpendicular to it. And the cubic dilatation \( \frac{1}{k} \) implies a linear dilatation, equal in all directions, amounting to \( \frac{1}{k} \).

On the whole, therefore, we have

- Linear elongation \( \frac{1}{k} \) in the direction of the applied stress, and
- Linear contraction \( \frac{1}{k} \) in all directions perpendicular to the applied stress.

47. Hence "Young's Modulus" = \( \frac{1}{k} \), and when the ends of a column, bar, or wire of isotropic material are acted on by equal and opposite forces, it experiences a lateral linear contraction equal to \( \frac{1}{k} \) of the longitudinal dilatation, each reckoned as usual per unit of linear measure. One specimen of the fallacious mathematics referred to in chap. xvi. of the mathematical theory below is a celebrated conclusion of Navier's and Poisson's that the ratio of lateral contraction to elongation by pull without transverse force is \( \frac{1}{2} \). This would require the rigidity to be \( \frac{1}{2} \) of the resistance to compression, for all solids; which was first shown to be false by Stokes in many obvious observations, proving enormous discrepancies from it in many well-known bodies, and rendering it most improbable that there is any approach to a constancy of ratio between rigidity and resistance to compression in any class of solids. Thus clear elastic jellies and India-rubber present familiar specimens of isotropic homogeneous solids which, while differing very much from one another in rigidity ("stiffness"), are probably all of very nearly the same compressibility as water, which is about \( \frac{1}{6000} \) per atmosphere. Their resistance to compression, measured by the reciprocal of this, is obviously many hundred times the absolute amount of the rigidity of the stiffest of those substances. A column of any of them, therefore, when pressed together or pulled out, within its limits of elasticity, by balancing forces applied to its ends (or an India-rubber band when pulled out), experiences no sensible change of volume, though very sensible change of length. Hence the proportionate extension or contraction of any transverse diameter must be sensibly equal to half the longitudinal contraction or extension; and such substances may be practically regarded as incompressible elastic solids in interpreting all the phenomena for which they are most remarkable. Stokes gave reasons for believing that metals also have in general greater resistance to compression, in proportion to their rigidities, than according to the fallacious theory, although for them the discrepancy is very much less than for the gelatinous bodies. This probable conclusion was soon experimentally demonstrated by Wertheim, who found the ratio of lateral to longitudinal change of lineal dimensions, in columns acted on solely by longitudinal force, to be about \( \frac{1}{2} \) for glass and brass; and by Kirchhoff, who, by a well-devised experimental method, found \( \frac{877}{500} \) as the value of that ratio for brass, and \( \frac{234}{500} \) for iron. For copper it is shown to lie between \( \frac{236}{500} \) and \( \frac{441}{500} \), by experiments quoted below, measuring the torsional and longitudinal rigidities of copper wires.

48. All these results indicate rigidity less in proportion to the compressibility than according to Navier's and Poisson's theory. And it has been supposed by many naturalists who have seen the necessity of abandoning that theory as inapplicable to ordinary solids that it may be regarded as the proper theory for an ideal perfect solid, and as indicating an amount of rigidity not quite reached in any real substance, but approached to in some of the

---

1 Mathematical Theory, chap. xvi.
3 "On the Elasticity and Viscosity of Metals" (W. Thomson), Proc. R. S., May 1865.
most rigid of natural solids (as, for instance, iron). But it is scarcely possible to hold a piece of cork in the hand without perceiving the fallaciousness of the last attempt to maintain a theory which never had any good foundation. By careful measurements on columns of cork of various forms (among them, cylindrical pieces cut in the ordinary way for bottles), before and after compressing them longitudinally in a Brann's press, we have found that the change of lateral dimensions is inelastic both with small longitudinal contractions and return dilations, within the limits of elasticity, and with such enormous longitudinal contractions as to $\frac{1}{4}$ or $\frac{1}{2}$ of the original length. It is thus proved decisively that cork is much more rigid, while metals, glass, and gelatinous bodies are all less rigid, in proportion to resistance to compression, than the supposed "perfect solid"; and the practical invalidity of the theory is experimentally demonstrated. By obvious mechanism of jointed bars a solid may be compressed, in one direction, and with such enormous lateral contractions as to $\frac{1}{4}$ or $\frac{1}{2}$ of the original length. Thus we have

**ELASTICITY**

It is to be understood that the vibrations in question are so much spread out through the lengths and the breadth of the body that mass does not enter...
veniently large numbers expressing moduli in grammes weight per square centimetre, but it is much better to reckon in millions of grammes per square centimetre.

52. "Resilience" is a very useful word, introduced about forty years ago (when the doctrine of energy was beginning to become practically appreciated) by Lewis Gordon, first professor of engineering in the university of Glasgow, to denote the quantity of work that a spring (or elastic body) gives back when strained to some stated limit and then allowed to return to the condition in which it rests when free from stress. The word "resilience" used without special qualification may be understood as meaning extreme resilience, or the work given back by the spring after being strained to the extreme limit within which it can be strained again and again without breaking or taking a permanent set. In all cases for which Hooke's law of simple proportionality between stress and strain holds, the resilience is obviously equal to the work done by a constant force of half the amount of the extreme force acting through a space equal to the extreme deflection.

53. When force is reckoned in "gravitation measure," resilience per unit of the spring's mass is simply the height that the spring itself, or an equal weight, could be lifted against gravity by an amount of work equal to that given back by the spring returning from the stresses over which it has been strained. Hence when we imagine the bar divided lengthwise and let the stress for which its resilience is allowed to return to the condition in which it rests when free from stress. The word "resilience" used without special qualification may be understood as meaning extreme resilience, or the work given back by the spring after being strained to the extreme limit within which it can be strained again and again without breaking or taking a permanent set. In all cases for which Hooke's law of simple proportionality between stress and strain holds, the resilience is obviously equal to the work done by a constant force of half the amount of the extreme force acting through a space equal to the extreme deflection.

54. Let the elastic body be a long homogeneous cylinder or prismatic with flat ends (a bar as we may call it for brevity), and let the stress for which its resilience is reckoned be *positive* normal pressures on its ends. The resilience per unit mass is equal to the greatest height from which the bar can fall with its length vertical, and impinge against a perfectly hard horizontal plane without suffering stress beyond its limits of elasticity. For in this case (as in the case of the direct impact of two equal and similar bars meeting with equal and opposite velocities, discussed in Thomson and Tait's *Natural Philosophy*, section 502), the kinetic energy of the translational motion proceeding the impact is, during the first half of the collision, wholly converted into potential energy of elastic force, which during the second half of the collision is wholly reconverted into kinetic energy of translational motion in the reverse direction. During the whole time of the collision the stopped end of the bar experiences a constant pressure, and at the middle of the collision the whole substance of the bar is for an instant at rest in the same state of compression as it would have permanently if in equilibrium under the influence of that pressure and an equal and opposite pressure at the other end. From the beginning to the middle of the collision the compression advances at a uniform rate through the bar from the stopped end to the free end. Every particle of the bar which the compression has not reached continues moving uniformly with the velocity of the waves before the collision until the compression reaches it, when it instantaneously comes to rest. The part of the bar which at any instant is all that is compressed remains at rest till the corresponding instant in the second half of the collision.

55. From our preceding view of a bar impinging against an ideal perfectly rigid plane, we see at once all that takes place in the real case of any rigorously direct longitudinal collision between two equal and similar elastic bars with flat ends. In this case the whole of the kinetic energy which the bodies had before collision reappears as purely translational kinetic energy after collision. The same would be approximately true even for any two bars, provided the time taken by a pulse of simple longitudinal stress to run through their lengths are equal. Thus if the two bars be of the same substance, or of different substances having the same value for Young's modulus, the lengths must be equal, but the diameters may be unequal. Or if the Young's modulus be different in the two bars, their lengths must (Math. Theory, chap. xvii.) be inversely as the square roots of its values. To all such cases the laws of "collision between two perfectly elastic bodies," whether of equal or unequal masses, as given in elementary dynamical treatises, are applicable. But in every other case part of the translational energy which the bodies have before collision is left in the shape of vibrations after collision, and the translational energy after collision is accordingly less than before collision. The losses of energy observed in common elementary dynamical experiments on collision between solid globes of the same substance are partly due to this cause. If they were wholly due to it they would be independent of the substance, when two globes of the same substance are used. They would bear the same proportion to the whole energy in every case of collision between two equal globes, or again, in every case of collision between two globes of any stated proportion of diameters, provided in each case the two which collide are of the same substances; but the proportion of translational energy converted into vibrations would not be the same for two equal globes as for two unequal globes. Hence when differences of proportionate losses of energy are found in experiments on different substances, as in Newton's on globes of glass, iron, or compressed wool, this must be due to imperfect elasticity of the material. It is to be expected that careful experiments upon hard well-polished globes striking one another with such gentle forces as not to produce even at the point of contact any stress approaching to the limit of elasticity, will be found to give results in which the observed loss of translational energy can be almost wholly accounted for by vibrations remaining in the globes after collision.

56. Examples of Resilience.—Example 1.—In respect to simple longitudinal pull, the extreme resilience of steel pianoforte wire of the gauge and quality referred to in section 22 above (calculated by means of the breaking weight into half the elongation produced by it according to the experimental data of section 22) is 6056 metre-grammes (gravitation measure) per ten metres of the wire. Or, whatever the length of the wire, its resilience is equal to the work required to lift its weight through 172 metres.

Example 2.—The torsional resilience of the same wire, twisted in either direction as far as it can be without giving it any notable permanent set, was found to be equal to the work required to lift its weight through 13 metres.

Example 3.—The extreme resilience of a vulcanized india-rubber band weighing 12·3 grammes was found to be equal to the work required to lift its weight through 1200 metres. This was found by stretching it by gradations of weights up to the breaking weight, representing the results by aid of a curve, and measuring its area to find the integral work given back by the spring after being stretched by a weight just short of the breaking weight.

57. Flexure of a Beam or Rod.—In the problem of simple flexure a bar or uniform rod or wire, straight when free from stress, is kept in a circular form by equal opposing couples properly applied to its ends. The parts of the bar on the convex side of the circle must obviously be stretched longitudinally, and those on the concave side contracted longitudinally, by the flexure. It is not obvious, however, what are the conditions affecting the lateral shrinkings and swellings of ideal filaments into which we may imagine the bar divided lengthwise. Earlier writers had assumed with perfect reason that each filament, bent as it is in its actual position in the bar, is elongated or contracted by the same amount as it would be if it were detached, and subjected to the same end pull or end compression with its sides quite free to shrink or
ELASTICITY

expand, but they had taken no account of the lateral shrinking or swelling which the filament must really experience in the bent bar. The subject first received satisfactory mathematical investigation from St Venant. He proved that the old supposition is substantially correct, with the important practical exception of the flat spring referred to in section 59 below. His theory shows that, in fact, if we imagine the whole rod divided parallel to its length into infinitesimal filaments, each of these shrinks or swells laterally with sensibly the same freedom as if it were separated from the rest of the substance and subjected to end pull or end compression, lengthening or shortening it in a straight line to the same extent as it is really lengthened or shortened in the circular arc which it becomes in the lateral with sensibly the same freedom as if it were.

The importancy of the angular beam, or a rectangular area in the normal section of a beam of any figure, is indicated, but too far to be included in the diagram of section 57. For unless the planed bar (or diameter perpendicular to the plane of flexure) be very small in comparison with the mean proportional between the radius OH and the thickness AB the distances from YY to the corners A', C', would fall short of the half thickness, OE, and the distances to B', D', would exceed it, by differences comparable with its own amount. This would give rise to sensibly less and greater shortenings and stretchings in the filaments towards the corners than those supposed in the ordinary calculation of flexural rigidity (article 61), and so vitiate the result. Unhappily, mathematicians have not hitherto succeeded in solving, possibly not even tried to solve, the beautiful problem thus presented by the flexure of a broadly thin band (such as a watch spring) into a circle of radius comparable with a third proportional to its thickness and its breadth.

60. But, provided the radius of curvature of the flexure is not only a large multiple of the greatest diameter, but also of a third proportional to the diameters in and perpendicular to the plane of flexure; then, however great may be the ratio of the greatest diameter to the least, the preceding solution is applicable, and it is remarkable that the necessary distortion of the normal section (illustrated in the diagram of article 57) does not sensibly impede the free lateral contractions and expansions in the filaments, even in the case of a broad thin lamina (whether of precisely rectangular section, or of unequal thicknesses in different parts). No. 61.

Flexural Rigidities of a Rod or Beam.-The example required to give unit curvature in any plane to a rod or beam is called its flexural rigidity for curvature in that plane. When the beam is of circular cross section and of isotropic material, the flexural rigidity is clearly the same, whatever be the plane of flexure through the axis, and the plane of the bending couple coincides with the plane of flexure. It might be expected that in a round bar of isotropic material, such as a wooden rod with the annual woody layers sensibly plane and parallel to a plane through its axis, would show different flexural rigidities in different planes,—in the case of wood, for example, different according as the flexure is in a parallel or perpendicular to the annual layers. This is not so, however; on the contrary, it is easy to show, by an extension of St Venant's theory, that in the case of the wooden rod the flexural rigidity is equal in all planes through the axis, and that the plane of flexure always agrees with the plane of the bending couple, and to prove generally that the flexure of a bar of isotropic substance, and composed it may be of longitudinal filaments of heterogeneous materials, is precisely the same as if it were isotropic, and that its flexural rigidities are calculated by the same rule from its Young's modulus, provided that the anisotropy is not such as (section 81) to give rise to alteration of the angle between the length and any diameter perpendicular to the length when weight is hung on the rod, or on any longitudinal filament cut from it. Excluding then all cases in which there is any such oblique anisotropy, we have a very simple theory for the flexure of bars of any substance, whether isotropic or anisotropic, and whether homogeneous or not homogeneous through the cross section.

62. Principal Flexural Rigidities and Principal Planes of Flexure of a Beam.—The flexural rigidity of a rod is generally not equal in different directions, and the plane of flexure does not generally coincide with the plane of the bending couple. Thus a flat ruler is much more easily bent in a plane perpendicular to its breadth than in the plane of its breadth; and if we apply opposing couples to its two ends in any plane through its axis not either perpendicular or parallel to its breadth, it is obvious that the plane in which the flexure takes place will be more inclined to the plane of the breadth than to the plane of the bending couple. Very elementary statical theory, founded on St.
Venant's conclusions of section 57, shows that, whatever the shape and the distribution of matter in the cross section of the bar, there are two planes at right angles to one another such that if the bar be bent in either of these planes the bending couple will coincide with the plane of those planes, and the rigidity of the bar for flexure in these planes are called its principal flexural rigidities. When the principal flexural rigidities are known the flexure of the bar in any plane oblique to the principal planes is readily found by supposing to be bent in one of the principal planes and simultaneously in the other, and calculating separately the couples required to produce these two component flexures. The positions of the principal planes of flexure, the relative flexural rigidities, and the law of elongation and contraction in different parts of the cross section, are found according to the following simple rules:

(1) Imagine an infinitely thin plane disc of the same shape and size as the cross section loaded with matter in simple proportion to the Young's modulus in different parts of the disc. Then the quantity of matter per unit area on any point of the disc be equal to the Young's modulus on the corresponding point of the rod when the material is homogeneous; on the other hand, when the material is homogeneous it is more convenient to call the quantity of matter unity per unit area of the disc. Considering different axes in the plane of the disc through the centre of inertia, find the two principal axes of greatest and least moments of inertia, and find the moments of inertia round them.

(2) In whatever plane the bar be bent it will experience neither elongation nor contraction in the filament which passes through the centre of inertia of the cross sections found according to rule (1), nor in the diameter of the cross section perpendicular to the plane of flexure.

(3) Thus all the particles which experience neither elongation nor contraction lie in a surface cutting the plane of flexure perpendicularly through the centres of inertia of the cross sections. All the material on the outside of this cylindrical surface is elongated, and all on the interior of it is contracted, in simple proportion to distance from it: the amount of the elongation or contraction being in fact equal to distance from this neutral surface divided by the radius of its curvature.

(4) Hence it is obvious that the portions of the solid on the two sides of any cross section most experience mutual normal forces, pulling them towards each other in the stretched part, and pressing them from one another in the condensed part, and that the amount of this negative or positive normal pressure per unit of area would be equal to the Young's modulus at the place, multiplied into the ratio of its distance from the neutral line of the cross section to the radius of curvature.

The sum of these positive and negative forces over the whole area of the cross section is zero in virtue of condition (3). Their couple resultant has its axis perpendicular to the plane of curvature when this line is either of the principal axes (3) of the cross section; and its moment is clearly equal to the moment of inertia of the material disc (1) divided by the radius of curvature. Hence the principal flexural rigidities are simply equal to the principal moments of inertia of this disc; and the principal flexural planes are the planes through its principal axes and the length of the bar; or taking the quantity of matter per unit area of the disc unity for the case of a homogeneous bar, we have the rule that the principal rigidities are equal to the product of the Young's modulus into the principal moments of inertia of the cross sectional areas, and the principal planes of flexure are the longitudinal planes through the principal axes of this area.

53. Law of Torsion.—One of the most beautiful applications of the general equations of internal equilibrium of an elastic solid hitherto made is that of M. de St Venant to "the torsion of prisms." In this work the mathematical methods invented by Fourier for the solution of problems regarding conduction of heat have been most ingeniously and happily applied by St Venant to the problem of torsion. To reproduce St Venant's mathematical investigation here would make this article too long (it occupies 237 quarto pages of the Mémoires des Savants Étrangers); but a statement of some of the chief results is given (sections 65–72), not only on account of their strong scientific interest, but also because they are of great practical value in engineering; and the reader is referred to Thomson and Tait's *Natural Philosophy*, sections 700–710, for the proofs and for further details regarding results, but much that is valuable and interesting is only to be found in St Venant's original memoir.

64. Torsion Problem stated and Torsional Rigidity defined.—To one end of a long, straight prismatic rod, wire, or solid or hollow cylinder of any form, a given couple is applied in a plane perpendicular to the length, while the other end is held fast: it is required to find the degree of twist produced, and the distribution of strain and stress throughout the prism. The moment of the couple divided by the amount of the twist per unit length is called the torsional rigidity of the rod or prism. This definition is founded simply on the extension of Hooke's law to torsion discovered experimentally by Coulomb, according to which a rod or wire when twisted within limits of torsional elasticity exerts a reactive couple in simple proportion to the angle through which one end is turned relatively to the other. The integral of the external conditions to be satisfied in the torsion problem are that the resultant action between the two sides of any normal section is a couple, in the normal plane, equal to the given couple. This problem has not hitherto been attacked for anisotropic solids. Even such a case as that of the round wooden rod (section 61) with annular layers sensibly parallel to a plane through its length, will, when twisted, experience a distribution of strain complicated much by its anisotropy. The following statements of results are confined to rods of isotropic material.

65. Torsion of Circular Cylinder.—For a solid or hollow circular cylinder, the solution (given first, we believe, by Coulomb) obviously is that each circular normal section remains unchanged in its own dimensions, figure, and internal arrangement (so that every straight line of its particles remains a straight line of unchanged length), but is twisted round the axis of the cylinder through such an angle as to give a uniform rate of twist equal to the applied couple divided by the product of the moment of inertia of the circular area (whether annular or complete to the centre) into the modulus of rigidity of the substance.

For, if we suppose the distribution of strain thus specified to be actually produced, by whatever application of stress is necessary, we have, in every part of the substance, a simple shear parallel to the normal section, and perpendicular to the radius through it. The elastic reaction against this requires, to balance it (section 43), a simple distorting stress consisting of forces in the normal section, directed as the shear, and others in planes through the axis, and directed parallel to the axis. The amount of the shear is, for parts of the substance at distance \( r \) from the axis, equal obviously to \( \tau r \), where \( \tau \) be the rate of twist reckoned in radians per unit of length of the cylinder. Hence the amount of the tangential force in either set of planes is numerically equal to the rigidity of the substance. Hence there is no force between parts of the substance lying on the two sides of any element of any circular cylinder coaxal with the bounding cylinder or cylinders; and consequently no force is required on the cylindrical boundary to maintain the supposed state of strain. And the mutual section between the parts of the substance on the two sides of any normal plane section consists of force in this plane, directed perpendicular to the radius through each point, and amounting to \( \tau r \) per unit of area. The moment of this distribution of force round the axis of the cylinder is (if \( d \) denote an element of the area) \( \tau dA \), or the
product of \( r \) into the moment of inertia of the area round the perpendicular to its plane through its centre, which is therefore equal to the moment of the couple applied at any end.

66. Prisms of any shape constrained to a Simple Torsion.—Further, it is easily proved that if a cylinder or prism of any shape be compelled to take exactly the state of strain above specified (section 65) with the line through the centres of inertia of the normal sections, taken instead of the axis of the cylinder, the mutual action between the parts of \( r \) on the two sides of any normal section will be a couple of the moment of inertia of the section round its centre, the two sides of any normal section will be a couple of the moment of inertia of the section round its centre. But for any other shape of prism than a solid or symmetrical hollow circular cylinder, the supposed state of strain requires, besides the terminal opposed couples, force parallel to the length of the prism, distributed over the prismatic boundary, in proportion to the distance of each in the tangent, from each point of the surface, to the point in which this line is cut by a perpendicular to \( r \) from \( O \) the centre of inertia of the normal section. To prove this let a normal section of the prism be represented in the annexed diagram (fig. 6) by \( PK \), representing the shear at any point \( P \), close to the prismatic boundary, be resolved into \( FN \) and \( PT \) parallel to the normal and tangent respectively. The whole, shear \( PK \) being equal to \( r \), its component \( FN \) is equal to \( r \) \( \sin \theta \) or \( r \) \( PE \). The corresponding component of the required stress is \( r \) \( PE \), and involves equal forces in the plane of the diagram, and in the plane through \( TP \) parallel to \( r \), each amounting to \( r \) \( PE \) per unit of area.

An application of force equal and opposite to the distribution thus found over the prismatic boundary, would of course alone produce in the prism, otherwise free, a state of strain which, compounded with that supposed above, would give the state of strain actually produced by the sole application of balancing couples to the two ends. The result, it is easily seen, consists of an increased twist, together with a warping of normally plane normal sections, by infinitesimal displacements perpendicular to themselves, into certain surfaces of antileastic curvature, with equal opposite curvatures. In bringing forward this theory, St Venant pointed out the falsity of the assumption admitted by several previous writers, and used in practice fallaciously by engineers, that Coulomb’s law holds for other forms of prism than the solid or hollow circular cylinder, but he discovered fully the nature of the requisite correction, reduced the determination of its action to a problem of pure mathematics, worked out the solution for a great variety of important and curious cases, compared the results with observation in a manner satisfactory and interesting to the naturalist, and gave conclusions of great value to the practical engineer.

67. Hydrokinetic Analogue to Torsion Problem.—We take advantage of the identity of mathematical conditions in St Venant’s torsion problem, and a hydrokinetic problem first solved a few years earlier by Stokes, to give the following statement, which will be found very useful in estimating deficiencies in torsional rigidity below the amount calculated from the fallacious extension of Coulomb’s law:

“Conceive a liquid of density \( \rho \) completely filling a closed infinitely light prismatic box of the same shape within as the given elastic prism and of length unity, and let a couple be applied to the box in a plane perpendicular to its length. The effective moment of inertia of the liquid will be equal to the correction by which the torsional rigidity of the elastic prism, calculated by the false extension of Coulomb’s law, must be diminished to give the true torsional rigidity. Further, the actual shear of the solid, in any infinitely thin plate of \( r \) between two normal sections, will at each point be, when reckoned as a differential sliding (section 43) parallel to their planes, equal to and in the same direction as the velocity of the liquid relatively to the containing box.”

68. Solution of Torsion Problem.—To prove these propositions and investigate the mathematical equations of the problem, the process followed in Thomson and Tait’s Natural Philosophy, section 706, is first to show that the conditions of sections 63 are verified by a state of strain compounded of (1) a simple twist round the line through the centre of inertia, and (2) a distortion of each normal section by infinitesimal displacements perpendicular to its plane; then find the interior and surface equations to determine this warping, and lastly, calculate the actual moment of the couple to which the mutual action between the matter on the two sides of any normal section is equivalent.

In the following are selected...

(1) Elliptic Cylinder.—The plane and dotted curvilinear area are (fig. 7) “contour lines” (coupes topographiques) of the section as warped by torsion; that is to say, lines in which it is cut by a series of parallel planes, each perpendicular to the axis. The arrows indicate the direction of rotation in the part of the prism above the plane of the diagram.
(2.) Contour lines for St Venant's "étoile à quatre points arrondis."—This diagram (fig. 8) shows the contour lines, in all respects as in case (1), for the case of a prism having for section the figure indicated. The portions of curves outside the continuous closed curve are merely indications of mathematical extensions irrelevant to the physical problem.

(3.) Contour lines of normal section of triangular prism, as warped by torsion, shown as in case (1) (fig. 9).

(4.) Contour lines of normal sections of square prisms, as warped by torsion (fig. 10).

(5.) Diagram of St Venant's curvilinear squares for which torsion problem is algebraically soluble.—This diagram (fig. 11) shows the series of lines represented by the equation \( z^2 + y^2 - \alpha(z^2 - 6z^2 + y^2) = 1 - \alpha \), with the indicated values for \( \alpha \). It is remarkable that the values \( \alpha = 0.5 \) and \( \alpha = -\frac{1}{2}(\sqrt{2} - 1) \) give similar but not equal curvilinear squares (hollow sides and acute angles), one of them turned through half a right angle relatively to the other.

70. Torsional Rigidity less in proportion to sum of principal Flexural Rigidity than according to false extension (section 66) of Coulomb's Law.—Inasmuch as the moment of inertia of a plane area about an axis through its centre of inertia perpendicular to its plane is obviously equal to the sum of its moments of inertia round any two axes through the same point at right angles to one another in its plane, the fallacious extension of Coulomb's law, referred to in section 66, would make the torsional rigidity of a bar of any section equal to the product of the ratio of the modulus of rigidity to the Young's modulus into the sum of its flexural rigidities (section 61) in any two planes at right angles to one another through its length.

The true theory, as we have seen (section 67), always gives a torsional rigidity less than this. How great the deficiency may be expected to be in cases in which the figure of the section presents projecting angles, or considerable prominences (which may be imagined from the hydrokinetic analogy given in section 67), has been pointed out by M. de St Venant, with the important practical application, that strengthening ribs, or projections (see, for instance, the second of the annexed diagrams), such as are introduced in engineering to give stiffness to beams, have the reverse of a good effect when torsional rigidity or strength is an object, although they are truly of great value in increasing the flexural rigidity, and giving strength to bear ordinary strains, which are always more or less flexural.

With remarkable ingenuity and mathematical skill he has drawn beautiful illustrations of this important practical principle from his algebraic and transcendental solutions.

Thus, for an equilateral triangle, and for the rectilinear and three curvilinear squares shown in the diagrams (fig. 12), he finds for the torsional rigidities the values stated. The number immediately below the diagram indicates in each case the fraction which the true torsional rigidity is of the old fallacious estimate (section 65)—the latter being the product of the rigidity of the substance into the moment of inertia of the cross section round an axis perpendicular to its plane through its centre of inertia. The second number indicates in each case the fraction which, the torsional rigidity is of that of a solid circular cylinder of the same sectional area.

71. Places of greatest Distortion in Twisted Prisms.—M. de St Venant also calls attention to a conclusion from his solutions which to many may be startling, that in his simpler cases the places of greatest distortion are those points of the boundary which are nearest to the axis of the twisted prism in each case, and the places of least distortion those farthest from it. Thus in the elliptic cylinder the
ELASTICITY

813

substance is most strained at the ends of the smaller principal diameter, and least at the ends of the greater. In the equilateral triangular and square prisms there are two lines of maximum strain through the middle of the sides. In the oblong rectangular prism there are two lines of greater maximum strain through the middle of the broader pair of sides, and two lines of less maximum strain through the middle of the narrower sides. The strain is, as we may judge from the hydrokinetic analogy, excessively small, but not evanescent, in the projecting ribs of a prism of the figure shown in (2) of section 69. It is quite evanescent infinitely near the angle, in the triangular and rectangular prisms, and in each other case, as (3) of section 69, in which there is a finite angle, whether acute or obtuse, projecting part of the edge; and generally bounded by any surfaces presenting acute or obtuse, cannot experience any finite stress or strain.

The solution shows that when the solid is continuous from the circular cylindrical surface to its axis, as in (4), (5), (6), the strain is zero or infinite according as the angle between the bounding planes of the solid is less than or greater than two right angles as in cases (4) and (6) respectively.

73. Changes of Temperature produced by Compressions or Dilatations of a Fluid and Stresses of any kind in an Elastic Solid.—From thermodynamic theory it is concluded that cold is produced whenever a solid is strained by opposing, and heat when it is strained by yielding to, any elastic force of its own, the strength of which would diminish if the temperature were raised; but that, on the contrary, heat is produced when a solid is strained against, and cold when it is strained by yielding to, any elastic force of its own, the strength of which would increase if the temperature were raised. When the strain is a condensation or dilatation, uniform in all directions, a fluid may be included in the statement. Hence the following propositions:

(1.) A cubic compression of any elastic fluid or solid in an ordinary condition causes an evolution of heat, but, on the contrary, a cubic compression produces cold in any substance, solid or fluid, in such an abnormal state that it would contract if heated while kept under constant pressure. Water below its temperature (3°9 Cent.) of maximum density is a familiar instance. (See table of section 76.)

(2.) If a wire already twisted be suddenly twisted further, always, however, within its limits of elasticity, cold will be produced; and if it be allowed suddenly to untwist, heat will be evolved from itself (besides heat generated externally by any work allowed to be wasted, which it does in untwisting). It is assumed that the torsional rigidity of the wire is diminished by an elevation of temperature, as the writer of this article had found it to be for copper, iron, platinum, and other metals (compare section 78).

(3.) A spiral spring suddenly drawn out will become lower in temperature, and will rise in temperature when suddenly allowed to draw in. (This result has been experimentally verified by Joule ("Thermodynamic Properties of Solids," Trans. Roy. Soc., 1858) and the amount of the effect found to agree with that calculated, according to the preceding thermodynamic theory, from the amount of the weakening of the spring which he found by experiment.)

(4.) A bar or rod or wire of any substance with or without a weight hung on it, or experiencing any degree of end thrust, to begin with, becomes cooled if suddenly elongated by end pull or by diminution of end thrust, and warmed if suddenly shortened by end thrust or by diminution of end pull, except abnormal cases in which with constant end pull or end thrust elevation of temperature produces shortening; in every such case pull or diminished thrust produces elevation of temperature, thrust or diminished pull lowering of temperature.

(5.) An india-rubber band suddenly drawn out (within its limits of elasticity) becomes warmer; and when allowed to contract, it becomes colder. Any one may easily verify this curious property by placing an india-rubber band in slight contact with the edge of the lips, then suddenly extending it—it becomes very perceptibly warmer: hold it for some time stretched nearly to breaking, and then suddenly allow it to shrink—it becomes quite startlingly colder, the cooling effect being sensible not merely to the lips but to the fingers holding the band. The first published statement of this curious observation is due to Gough (Memorials of the Literary and Philosophical Society of Manchester, 2d series, vol. i. p. 288), quoted by Joule in his paper on "Thermodynamic Properties of Solids" (Transactions of Royal Soc., 1858). The thermodynamic conclusion from it is that an india-rubber band, stretched by a constant weight of sufficient amount hung on it, must, when heated, pull up the weight, and, when cooled, allow the weight to descend; this Gough, independently of thermodynamic theory, had found to be actually the case. The experiment any one can make with the greatest ease is by hanging a few pounds weight on a common india-rubber band, and taking a red-hot coal in a pair of tongs, or a red-hot poker, and moving it up and down close to the band. The way in which the weight rises when the red-hot body is near, and falls when it is removed, is quite startling. Joule experimented on the amount of shrinking per degree of elevation of temperature, with different weights hung on a band of vulcanized india-rubber, and found that they closely agreed with the amounts calculated by Thomson's theory from the heating effects of pull, and cooling effects of ceasing to pull, which he had observed in the same piece of india-rubber.
ELASTICITY

74. The thermodynamic theory gives one formula by which the change of temperature in every such case may be calculated when the other physical properties are known:—

\[ \theta = \frac{t}{F P} ; \]

where \( \theta \) denotes the elevation of temperature produced by the sudden application of a stress \( P \);

\( t \), the temperature of the substance on the absolute thermodynamic scale, the change of temperature \( \theta \) being supposed to be but a very small fraction of \( t \);

\( e \), the geometrical effect (expansion or other strain) produced by an elevation of temperature of one degree when the body is kept under constant stress;

\( K \), the specific heat of the substance per unit mass under constant stress;

\( p \), the density;

and \( J \), Joule's equivalent (taken as 42400 centimetres).

In using the formula for a fluid, \( p \) must be normal pressure equal in all directions, or normal pressure on a set of parallel planes, or tangential traction on one or other of the two sets of mutually perpendicular parallel planes which (section 43) experience tangential traction when the body is subjected to a simple distorting stress; or, quite generally, \( p \) may be the proper numerical reckoning (Mathematical Theory, chap. x.) of any stress, simple or compound. When \( p \) is pressure uniform in all directions, \( e \) must be expansion of bulk, whether the body expands equally in all directions or not. When \( p \) is tangential to a set of parallel planes, \( e \) must be expansion in the direction opposed to this pressure, irrespective of any change of shape not altering the distance between the two planes of the solid perpendicular to the direction of \( p \). When \( p \) is a simple tangential stress, reckoned \( \pm \) as in section 43, \( e \) must be the change, reckoned in fraction of the radius, of the angle, infinitely nearly a right angle, between the two sets of parallel planes in either of which there is the tangential traction denoted by \( p \). In each of these cases \( p \) is reckoned simply in units of force per unit of area. Quite generally \( p \) may be any stress, simple or compound, and \( e \) must be the component (Math. Th., chap. viii. and ix.) to the type of \( p \), of the strain produced by an elevation of temperature of one degree when the body is kept under constant stress. The constant stress for which \( K \) and \( e \) are reckoned ought to be the mean of the stresses which the body experiences with and without \( p \). Mathematically speaking, \( p \) is to be infinitesimal, but practically it may be of any magnitude moderate enough not to give any sensible difference in the value of either \( K \) or \( e \), whether the "constant stress" be with \( p \) or without \( p \), or with the mean of the two: thus for air \( p \) must be a small fraction of the whole pressure, for instance a small fraction of one atmosphere for air at ordinary pressure, for water or watery solutions of salts or other solids, for mercury, for oil, and for other known liquids \( p \) may, for all we know, amount to twenty atmospheres or one hundred atmospheres without transgressing the limits for which the preceding formula is applicable. When the law of variation of \( K \) and \( e \) with pressure is known, the differential formula is readily integrated to give the integral amount of the change of temperature produced by greater stress than those for which the differential formula is applicable. For air and other permanent gases Boyle's law of compression and Charles's law of thermal expansion supply the requisite data with considerable accuracy up to twenty or thirty atmospheres. The result is expressed by the formula:

\[ \frac{t + \theta}{t} = \left( \frac{P + P_{0}}{P} \right)^{1/\gamma} \]

where \( k \) denotes the ratio of the thermal capacity, pressure constant, to the thermal capacity, volume constant, of the gas, a number which thermodynamic theory proves to be approximately constant for all temperatures and densities, for any fluid approximately fulfilling Boyle's and Charles's laws;

\( P \) and \( t \) the initial pressure and temperature of the gas;

\( P_{0} \) the sudden addition to the pressure;

and, as before, \( \theta \) the elevation of temperature.

For the case of \( p \) a small fraction of \( P \) the formula gives:

\[ \theta = (k - 1) \frac{P}{t} \]

It is by an integration of this formula that (1) is obtained.

For common air the value of \( k \) is very approximately 1.41. Thus if a quantity of air be given at 15° C. (\( t = 289^\circ \)) and the ordinary atmospheric pressure, and if it be compressed gradually up to 23 atmospheres, or diluted to \( \gamma \) of an atmosphere, and perfectly guarded against gain or loss of heat from or to without, its temperature at several different pressures, chosen for example, will be according to the following table of excesses of temperature above the primitive temperature, calculated by (1).

### TABLE SHOWING EFFECTS OF PRESSURE ON TEMPERATURE.

</table>

But we have no knowledge of the effect of pressures of several thousand atmospheres in altering the expansibility or specific heat in liquids, or in fluids which at less heavy or at ordinary pressures are "gases."

75. When change of temperature, whether in a solid or a fluid is produced by the application of a stress, the corresponding modulus of elasticity will be greater in virtue of the change of the temperature than what may be called the static modulus defined as above, on the understanding that the temperature if changed by the stress is brought back to the primitive temperature, calculated by (1).

**Elasticity**

\[ p = \frac{e}{L} \]

Dividing \( p \) by this expression we find for the kinetic modulus

\[ M' = \frac{1}{\frac{e}{L}} \]

Hence

\[ M' = \frac{1}{e} \]

76. For any substance, fluid or solid, it is easily proved, without thermodynamic theory, that

\[ M' = \frac{K}{N} \]

where \( K \) denotes the thermal capacity of a stated quantity of the substance under constant stress, and \( N \) its thermal capacity under constant strain (or thermal capacity when the body is prevented from change of shape or change of volume). For permanent gases, and generally for fluids approximately fulfilling Boyle’s and Charles’s laws as above, \( K \) is proved by thermodynamic theory to be approximately constant. Its value for all gases for which it has been measured differs largely from unity, and probably also for liquids generally (except water near its temperature of maximal density).

On the other hand, for solids whether the stress considered be uniform compression in all directions or of any other type, the value of \( M' \) or \( K \) differs but very little from unity; and both for solids and liquids it is far from constant at different temperatures (in the case of water it is zero at \( 3^\circ \) Cent., and varies as the square of the difference of the temperature from \( 3^\circ \) at all events for moderate differences from this critical temperature, whether above or below it). The following tables show the value of \( M' \) or \( K \), and the value of \( \theta \) by the formula of sec. 74, for different fluid and solid substances at the temperature 15° Cent. (289° absolute scale). The first table is for compression uniform in all directions, the second, necessarily confined to solids, is for the stress dealt with in “Young’s Modulus,” that is, normal pressure (positive or negative) on one set of parallel planes, with perfect freedom to expand or contract in all directions in these planes. A wire or rod pulled longitudinally is a practical application of the latter

77. Experimental Results.—The following tables show determinations of moduluses of compression, of Young’s modulus, and of moduluses of rigidity by various experimenters and various methods. It will be seen that the Young’s moduluses obtained by Wertheim by vibrations, longitudinal or transverse, are generally in excess of those which he found by statics, but the differences are enormously greater than those due to the heating and cooling effects of elongation and contraction (section 76), and are to be certainly reckoned as errors of observation. It is probable that his moduluses determined by static elongation are minutely accurate, the discrepancies found by vibrations are probably due to imperfections of the arrangements for carrying out the vibrational method:

*Values in grammea per centimetre, and in terms of 10000000 ft.*
78. A question of great importance in the physical theory of the elasticity of solids, "What changes are produced in the modulus of elasticity by permanent changes in its molecular condition," has occupied the attention, no doubt, of every "naturalist" who has studied the subject, and valuable contributions to its answer by experiment had been given by Wertheim and other investigators, but solely with reference to Young's modulus. In 1865 an investigation of the effect of the torsional rigidity of wires of different metals, produced by stretching them longitudinally beyond their limits of elasticity, was commenced in the physical laboratory of the university of Glasgow in its old buildings in 1865. The following description of experiments is extracted from the paper by W. Thomson "On the Elasticity and Viscoelasticity of Metals," already quoted (section 30), with reference to viscosity and fatigue of elasticity.

"To determine rigidity by torsional vibrations, taking advantage of an obvious but most valuable suggestion made to me by Dr Joule, I used as vibrator in each case a thin cylinder of brass, of 1 inch in diameter. The cylinder was placed in a crucible filled with water and distilled. The water was repeatedly raised to a boil and allowed to cool slowly, so that it could carefully be touched without breaking it, and which had been found to be reduced in density by this process to as low as 0.767. The 1865 experiments, therefore, are all commercial specimens—those of copper being all, or nearly all, cut from bars supplied by the Giffard, Latour, and Son Company, having been selected as of high electrical conductivity, and of good mechanical quality, for submarine cables.

It ought to be remarked that the change of molecular condition produced by permanently stretching a wire or solid cylinder of metal is a certain change from a condition which, if originally isotropic, becomes anisotropic as to some qualities, and that the changed conditions may be presumed to be so anisotropic as to elasticity. If so, the rigidity corresponding to the direct and diagonal directions (indicated by No. 1 and No. 2 in fig. 14) must in all probability become different from one another when a wire is permanently stretched, instead of being equal as they must be when the substance is isotropic. It becomes, therefore, a question of extreme interest to find whether rigidity No. 2 is not increased by this process, which, as is shown by the experiments above described, diminishes, to a very remarkable degree, the rigidity No. 1. The most obvious experiment, and indeed the only practicable experiment, adapted to answer this question, for a wire or round bar is that of Cagniard-Lattre, in which an accurate determination of the difference produced in the volume of the substance as made by applying and removing longitudinal traction within its limits of elasticity. With the requisite apparatus, which must be much more accurate than that of Cagniard-Lattre, a most important and interesting investigation might be made. The results, along with an accurate determination of the Young's modulus for the particular case, give (sec 47) the modulus of compression, and the rigidity

Remarks.
1. Only forty vibrations from initial arc of convenient amplitudes could be counted. Had been stretched considerably before this experiment.
2. So minute that only twenty vibrations could be counted.
3. In the preceding stretch.
4. A piece of the preceding stretched.
5. The preceding made red-hot in a crucible filled with powdered charcoal and allowed to cool slowly, became very brittle a part of it with difficulty saved for the experiment.
6. Another piece of the long (2450 centim.) wire; stretched by successive simple tractions.
7. A new gauge copper wire, stretched with successive tractions.
8. A fine gauge copper wire, suffered by being heated to redness and plunged in water. A length of 250 centimeters cut from this, suspended, and elongated by successive simple tractions.
9. Another length of 250 centimeters cut from the same, and similarly treated.
10. One piece, successively elongated by simple tractions till it broke.

The above results are from Wertheim’s “Mémoires” on Elasticity, Ann. de Chem. et Phys., tom xii. (1844).

The change in the rigidity-modulus produced by change of temperature was investigated by Kohlschütz. He found that it is expressed by the formula \( a = n \alpha - \beta c \), where \( n \) denotes the value of the rigidity-modulus at \( 0 \)° C, \( \alpha \), \( \beta \), coefficients the values of which for iron, copper, and brass are as follows:

80. Tempering soft iron by long-continued stress.

Preliminary experiments by Mr J. T. Bottomley towards the investigation promised in section 5 above have discovered a very remarkable property of soft iron wire respecting its ultimate tensile strength. Eight different specimens, tested by the gradual application of more and more weight within ten minutes of time in each case until the wire broke, bore from 45 1/2 to 46 1/2 lb (average 45 1/2) just before breaking, with elongations of from 17 per cent to 25 per cent. Another specimen left with 43 lb hanging on it for 24 hours, and then tested by the gradual addition of weights during 25 minutes till it broke, bore 49 1/2 lb before breaking, with elongation of 15 per cent. Another left for 3 days 11 hours 40 minutes with 43 lb hanging on it, and then tested by the gradual addition of weights during 31 minutes till it broke, bore 51 1/2 lb just before breaking, with elongation of 14 1/4 per cent. Another specimen of the same wire was set up with 40 lb hanging on it on the 5th of July 1867, on the 6th of July 3 lb were added, on the 9th 4 lb more, and on the 10th 3 lb more, making in all on this date 45 lb. Thereupon continued day by day, with occasional intervals of two days or three days, the weight was increased first by half a pound at a time, and latterly by a quarter of a pound at a time, until on the 3d of September the wire broke with 57 1/2 lb (elongation not recorded). This gradual addition of weight therefore had increased the tensile strength of the metal by 20 7/8 per cent.

81. Experiments made for this article.—There are many subjects in the theory of elasticity regarding which information to be obtained by experiment only is greatly wanted. Several of these have been pointed out above (section 21), and while this article was being put in type, experiments were made in the university of Glasgow with a view of answering some of the questions proposed. Mr Donald Macfarlane, besides making the experiments referred to in sections 3 and 21, investigated the effects of applying different amounts of pull to a steel pianoforte wire which had been twisted to nearly its limits of elasticity, and which was kept twisted by means of a couple. The results proved a deviation from Hooke’s law by showing a diminution of the torsional rigidity, of about 1.6 per cent., produced by hangmg a weight of 112 lb on the wire. Of this 1.2 per cent. is accounted for by elongation and by shrinkage of the diameter, leaving 4 per cent. of diminution of the rigidity-modulus.

It was also found that when the wire was twisted far beyond its limits of elasticity, and then freed from torsional stress, a weight hung on it caused it to untwist slightly. When the weight was removed and reapplied again and again, the lower end of the wire always turned in the same direction as the permanent twist when the weight was removed, and in the opposite direction when it was applied. This result shows the development of molotropism in the substance of the wire, according to which a small cube cut from any part of it far out from the axis, with two sides of the cube parallel to the length, and the other two pairs of sides making angles of 45° with the length, would show different compressibilities in the directions perpendicular to the last-mentioned pairs of sides.

Another very interesting result, discovered in the course of these experiments, was that when a length of five metres of the steel wire, with a weight of 39 lb hung upon it, was twisted to the extent of 95 turns, it became gradually elongated to the extent of \( \frac{1}{2} \) of the length of the wire; when further twisted it began to shorten till, when 25 turns had been given (in all 120 turns), the weight had risen from its lowest position through nearly \( \frac{1}{8} \) of the length of the wire, so that the previous elongation had been diminished by about \( \frac{1}{4} \) of its amount.

Experiments were also made by Mr Andrew Gray and Mr Thomas Gray for the purpose of determining the effects of various amounts of permanent twist in altering the rigidity-modulus and the Young’s modulus of wires of copper, iron, and steel. A copper wire, of 3.15 metres in length and 154 centimetre diameter, No. 17 B.W.G., which had a rigidity-modulus of 442 million grammes per square centimetre to begin with, was found to have 420 after 10 turns, showing a diminution in the modulus of \( \frac{1}{4} \) of its original value. There was little further change until 150 turns had been given, when the modulus began to increase. At 1525 turns its value was 373, and at 1625 it was 377. Twenty turns more broke the wire before the torsional elasticity had been again determined.

A piece of iron wire of nearly the same length, about three metres, but of smaller diameter (087 centimetre), showed continued diminution of torsional rigidity as far as
1350 turns of permanent twist, when the diminution had amounted to 14 per cent. of the primitive value, 36 turns more broke the wire, and another determination of torsional rigidity had been made.

The steel pianoforte wire also showed a diminution of torsional rigidity with permanent twist, and (as did the copper wire) showed first a diminution and then a slight augmentation of the amount which had been discovered in the copper wire, and the ultimate augmentation was considerably greater in the steel than what it had been in the copper before rupture. Thus after 473 turns of permanent twist the torsional modulus had diminished from 751 million grammes per square centimetre to 414 1 95 more turns of permanent twist augmented the rigidity from 414 to 430, and when further twisted the wire broke before another observation had been made. The vibrator used in these experiments was a cylinder of lead weighing 56 lb., which was kept hanging on the wire while it was being twisted, and in fact during the whole of about 100 hours from the beginning of the experiment till the wire broke, except on two occasions for a few minutes, while the top fastening which had given way was being replaced. The period of vibration was augmented from 39-375 seconds to 51-9 seconds by the twist. The wire took the twist very irregularly, some parts not beginning to show much signs of permanent twist till near the end of the experiment.

In two specimens of copper wire of the same length and gauge, one of which was drawn about the Young's modulus was found to be increased 10 per cent by 100 turns of permanent twist.

Five metres of the steel pianoforte wire, bearing a weight of 39 lb., was in one of Mr. McFarlane's experiments twisted 1290 turns, and then allowed to untwist, and 384 turns came out, leaving the wire in equilibrium with 81 2 turns of permanent twist. Its Young's modulus was then found not to differ as much as 1/2 per cent, from the value it had before the wire was twisted.

MATHEMATICAL THEORY OF ELASTICITY.

PART I—On Stressess and Stresses 2

I. Definitions and Explanations

Def. An stress is an equilibrating application of force to a body.

Cor. The stress on any part of a body in equilibrium will thus signify the force which it experiences from the matter touching that part and that matter, whether elastic or inelastic with itself, or only across a portion of its bounding surface.

Def. A strain is any definite alteration of form or dimensions experienced by a solid.

Examples.—Equal and opposite forces acting at the two ends of a wire or rod of any substance will elongate a string upon it. A body pressed equally all round—for instance, any mass touched by air on all sides—will experience a stress. A stone in a load will experience a stress if it is pressed upon by another stone, or by any parts of the structure, in contact with it. Any part of a continuous solid must simply set up on a solid base, experience stress from the surrounding parts in consequence of its weight. The different parts of a ship in a heavy sea experience stresses from both which they are except when the water is smooth.

If a rod of any substance becomes either longer or shorter, it is said to experience a strain. If a stone, a beam, or any mass of metal in a building, or in a piece of furniture, be of large dimensions or inclined, or twisted, or distorted in any way, it is said to experience a strain, to become strained, or often in common language simply "to strain." A ship may be said to "strain" if it is heeling, or when working in a heavy sea, the different parts of it experience relative motions.

CHAPTER II—Homogeneous Stressess and Homogeneous Strains

Def. A stress as equal and simultaneous through a body when equal and similar portions of the body, with corresponding lines parallel, experience equal and parallel forces or tensions on corresponding elements of their surfaces.

Cor. When a body is subjected to any homogeneous stress, the mutual tension or pressure between the parts of it on two sides of any plane amounts to the same per unit of surface as that between the parts on the two sides of any parallel plane, and the former tension or pressure is parallel to the latter.

A strain is said to be homogeneous throughout a body, or the body is said to be homogeneously strained, when equal and similar portions, with corresponding lines parallel, experience equal and similar alterations of dimensions.

Cor. All the particles of the body in parallel planes remain in parallel planes, when the body is homogeneously strained in any way.

Examples.—A long uniform rod, if pulled out, or a pillar loaded with a weight, will experience a uniform stress, even at its ends. There will be a sensible resistance to the attempt of flattening the ends of the pillar, or of causing the two top plates of a cylindrical vessel to press against each other in consequence of the ends being extended in the same extent as the middle does.

A piece of steel held in a plane and distorted so that a webby and wool instead of being perpendicular to this, is, by some two planes parallel cutting one another obliquely, experiences a homogeneous strain. The strain is homogeneous as it respects to the area of the web in the same extent as the middle does.

CHAPTER III—On the Equilibrium of Forces in a Strain

Theorem.—In every homogeneous stress there is a system of three rectangular planes, each of which is perpendicular to the direction of the mutual force between the parts of the body on its two sides.

For let P(X), P(Y), P(Z) denote the components, parallel to X, Y, Z, any three rectangular lines of reference of the force experienced per unit of surface at any portion of the solid bounded by a plane parallel to (Y, Z), Q(X), Q(Y), Q(Z), the corresponding components of the force experienced by any surface of the solid parallel to (Z, X), and R(X), R(Y), R(Z), those of the force at a surface parallel to (X, Y).

Now, by considering the equilibrium of a cube of the solid with faces parallel to the planes of reference (fig 15), we see that the couple of forces Q(Z) on its two faces perpendicular to Y is balanced by the couple of forces R(Y) on the faces perpendicular to Z. Hence we must have

\[ Q(Z) = R(Y) \]

Similarly, it is seen that

\[ R(X) = P(Z) \]

and

\[ P(Y) = Q(X) \]

For the case of brevity, these pairs of equal quantities (being tangential forces respectively perpendicular to X, Y, Z) may be denoted by T(X), T(Y), T(Z).

Consider a tetrahedral portion of the body surrounded it may with continuous solid) contained within three planes A, B, C, through a point O parallel to the planes of lines of reference, and a third plane K cutting these at angles a, b, c respectively, so that as regards the areas of the different sides we shall have

\[ A = \cos a + \cos b \cos c + \cos \gamma \cos \theta \]

The forces actually experienced by the sides A, B, C have nothing to balance them except the force actually experienced by K. Hence those three forces must have a single resultant, and the force on K must be equal and opposite to it. If, therefore, the force on K per unit of surface is denoted by F, and its direction comes by i, m, n, we have

\[ F \sin i = T(X) \sin m = T(Z) \sin n \]

and, by the relations between the cases stated above, we deduce

\[ F = T(X) \sin m = T(Z) \sin n \]

Hence the problem of finding (a, b, g), so that the force F (i, m, n) may be perpendicular to it can be solved by substituting cos a, cos b, cos c, cos \( \gamma \) for i, m, n in those equations. By the elimination of cos a, cos b, cos \( \gamma \) from the three equations thus obtained, we have the well-known cubic determinant equation, of which the roots necessarily real, lead, when two of them are equal, to one and only one system of three rectangular axes having the stated property.
Def. The three lines thus proved to exist for every possible homogeneous strain are called the axes of the strain, or the strain-normals; their planes are called its normal planes; the mutual forces between parts of the body separated by these planes, or the forces on portions of the body parallel to them, are called the principal tensions.

Cor. 1. The Principal Tensions of the strain are the roots of the determinant cubic referred to in the demonstration.

Def. If the notation \( F(x, y, z) \), etc., explained above, its normal planes are the principal planes of the surface of the second degree whose equation is

\[
F(x^2 + y^2 + z^2) + 2F'x'y'z' + F''x'^2 + F''y'^2 + F''z'^2 = 0,
\]

and the principal tensions are equal to the reciprocals of the squares of the lengths of the semi-principal-axes of the same surface (quantities which are negative of course for the principal axis or axes which cut the surface when the surface is a hyperboloid of one or of two sheets).

Cor. 3. The ellipsoid whose equation, referred to the rectangular axes of a strain

\[
g - 2F'x'y'z' = 2F''x'^2 + 2F''y'^2 + 2F''z'^2 = 1,
\]

where \( F, G, H \) denote the principal tensions, and \( e \) any infinitely small quantity, represents the strain, in the following manner.

From any point \( P \) in the surface of the ellipsoid draw a line in the tangent plane half-way to the point where this plane is cut by a perpendicular to it through the centre; and from the end of the first-mentioned line draw a radial line to meet the surface at a sphere of unit radius concentric with the ellipsoid. The tension at this point of the surface of the solid is in the line from it to the point \( P \); and its amount per unit of surface is equal to the length of a small line, divided by \( e \).

Cor. 4. Any stress is fully specified by six quantities, viz., its three principal stresses \( (F, G, H) \), and three angles \( \theta, \phi, \psi \) or three numerical quantities equivalent to the nine direction cosines specifying its axes.

CHAPTER IV.—On the Distribution of Displacements in a Strain.

Prop. In every homogeneous strain any part of the solid bounded by an ellipsoid remains bounded by an ellipsoid.

For all particles of the solid in a plane remain in a plane, and two parallel planes parallel. Consequently every system of equiangular diametral planes of an ellipsoid of the solid retain the property of equiangular diametral planes with reference to the altered surfaces containing the same particles. Thus altered surface is therefore an ellipsoid.

Prop. There is a single system (and only a single system, except in the cases of symmetry) of three rectangular planes for every homogeneous strain, which remain at right angles to one another in the altered solid.

Def. 1. These three planes are called the normal planes of the strain, or simply the strain-normals. Their lines of intersection are called the axes of the strain. The elongations of the solid per unit of length along these axes are termed the normal elongations; to these planes are called the Principal Elongations of the strain.

Remark. The preceding propositions and definitions are not limited simply to ellipsoids, but are applicable to whatever extent the body may be strained.

Prop. If a body, while experiencing an infinitely small strain, be held in position, its plane fixed, and the normal planes of two parallel to three fixed rectangular planes through the point \( O \), a sphere of the solid of unit radius having this point for its centre becomes, when strained, an ellipsoid, whose equation, referred to the strain-normals through \( O \), is

\[
(1 - 2F) = 0 + (2F - 1) + (2F' - 1) = 0,
\]

if \( x, y, z \) denote the elongations of the solid per unit of length, in the directions respectively perpendicular to these three planes, and \( F, F', F'' \) on the surface of this ellipsoid, attains by any particular point of the solid, is such that if a line be drawn in the tangent plane, half-way to the point of intersection of this plane with a perpendicular from the centre, a radial line drawn through its extremity cuts the primitive spherical surface in the primitive position of that point.

Cor. 1. For every stress, there is a certain infinitesimally small strain, and conversely, for every infinitesimally small strain, there is a certain stress, namely if, while the strain in being acquired, the centre and the strain-normals through it are unmoved, the absolute displacements of particles belonging to a spherical surface of the solid of unit intensity (according to a definite convention as to units for the representation of force by lines) and in direction, the forces (reckoned as to intensity, in amount per unit of area) experienced by the enclosed sphere of the solid, at the different parts of its surface, when subjected to the stress.

Cor. 2. Any strain is fully specified by six quantities, viz., its three principal elongations, and three numerical quantities equivalent to three independent quantities specifying its axes.

Def. 2. A stress and an infinitely small strain related in the manner defined in Cor. 1, is to be of the same type, or to be of the same kind, that ellipsoid by means of which the distribution of force over the surface of a sphere of unit radius is represented in one case, and by means of which the displacements of particles from the spherical surface are shown in the other, may be called the geometrical type of either.

Cor. Any stress or strain-type is fully specified by six quantities, viz., two ratios between its principal strains or elongations and three quantities specifying the angular position of its axes.

CHAPTER V.—Conditions of Perfect Concurrency between Strains and Strains.

Def. 1. Two stresses are said to be concurrent in direction, or to be perfectly concurrent, when they only differ in absolute magnitude. The same relative designations are applied to two strains differing from one another only in magnitude, and not in type.

Def. 2. When a homogeneous stress is such that the normal component of the mutual force between the parts of the body on the two sides of any plane whatever, across it, is proportional to the augmentation of distance between the same plane and another parallel to it and initially at unit of distance, due to a certain strain experienced by the same body, the stresses so caused are said to be perfectly concurrent; also to be coincident in direction. The body is said to be yielding directly to a stress applied to it. But it is as if the strain was varying from the time it was acquired a strain directly opposed to the stress; and in the same circumstances, the matter round the body is said to be yielding directly to the reactive stress of the body upon it.

CHAPTER VI.—Orthogonal Strains and Strains.

Def. 1. A stress is said to act across a strain, or to act orthogonally to a strain, or to be orthogonal to a strain, if work is neither done upon nor by the body in virtue of the action of the stress upon it while it is acquiring the strain.

Def. 2. Two stresses are said to be orthogonal when either coincides in direction with a strain orthogonal to the other.

Def. 3. Three stresses are said to be orthogonal when either coincides in direction with a stress orthogonal to the other.

Example.—(1) A uniform central compression, and any strain involving no alteration of volume, are orthogonal to one another.

(2) A simple extension of contraction in parallel lines unaccompanied by any transverse extension or contraction, that is, "a simple longitudinal strain," is orthogonal to any similar strain in lines so situated as to be conjugate in a simple diagonal.

(3) A simple longitudinal strain is orthogonal to a "simple tangential strain," 1 in which the sliding is parallel to its direction of action.

(4) Two infinitely small simple tangential strains in the same plane, with diametral planes of sliding mutually perpendicular, are orthogonal to one another.

(5) An infinitely small simple tangential strain is orthogonal to every infinitely small simple tangential strain, in a plane either parallel to its plane of sliding or perpendicular to its line of sliding.

CHAPTER VII.—Composition and Resolution of Strains and their Relations with each other.

Any number of simultaneously applied homogeneous strains are equivalent to a single homogeneous stress which is called their resultant. Any number of superposed homogeneous strains are equivalent to a single homogeneous resultant strain. Infinitesimal small strains may be independently superposed; and in what follows it will be uniformly assumed that all strains spoken of are infinitely small, unless the contrary is stated.

Example.—(1) A strain consisting simply of elongation in one set of parallel lines, and a strain consisting of equal reduction in another set of parallel lines, either of these being acquired, the centre and the strain-normals through it are unmoved, the absolute displacements of particles belonging to a spherical surface of the solid of unit intensity (according to a definite convention as to units for the representation of force by lines) and in direction, the forces (reckoned as to intensity, in amount per unit of area) experienced by the enclosed sphere of the solid, at the different parts of its surface, when subjected to the stress.

Cor. 1. For every stress, there is a certain infinitesimally small strain, and conversely, for every infinitesimally small strain, there is a certain stress, namely if, while the strain in being acquired, the centre and the strain-normals through it are unmoved, the absolute displacements of particles belonging to a spherical surface of the solid of unit intensity (according to a definite convention as to units for the representation of force by lines) and in direction, the forces (reckoned as to intensity, in amount per unit of area) experienced by the enclosed sphere of the solid, at the different parts of its surface, when subjected to the stress.

Cor. 2. Any strain is fully specified by six quantities, viz., its three principal elongations, and three numerical quantities equivalent to three independent quantities specifying its axes.

1. That is, a homogeneous strain in which all the particles in one plane remain in their places, and other particles are displaced in the directions of angles \( (\theta, \phi, \psi) \), or three direction cosines, equivalent to three independent quantities specifying its axes.
ELASTICITY

Chapter XII.—On the Measurement of Stresses and Strains

Def. Strains of any type are said to be to one another in the same ratio as stresses of the same type respectively, when any particular plane of the solid acquires, relatively to another plane parallel to it, motions in virtue of the strains which are to one another in the same ratio as the normal components of the forces between the parts of the solid on the two sides of either plane due to the respective stresses.

Def. The magnitude of a stress and of a strain of the same type are quantities which, multiplied one by the other, give the work done upon unit of volume of a body solid on by the strain while acquiring the strain.

Cor. 1. If \( x, y, z, \xi, \eta, \zeta \) denote orthogonal components of a certain strain, and if \( P, Q, K, S, T, U \) denote components, of the same type respectively, of a stress applied to a body while acquiring that strain, the work done upon it per unit of its volume will be

\[
Ap = Pr + Qy + &c
\]

Each member must be equal to

\[
F^2 + \eta^2 + \xi^2
\]

and also equal to

\[
F^2 + \eta^2 + \xi^2
\]

When

\[
F^2 = \eta^2 + \xi^2
\]

Hence

\[
F^2 = \eta^2 + \xi^2
\]

or

\[
F^2 = \eta^2 + \xi^2
\]

or

\[
F^2 = \eta^2 + \xi^2
\]

Now we have, to express the proportionality of the stresses and strains,

\[
F = \frac{P}{x} = \frac{Q}{y} = \frac{K}{z}
\]

and the several components will be \( P, Q, K, \) &c., and therefore referring to types of reference. The

the resultant of any strain whatever belonging to the others.

Def. A normal system of types of reference is that in which the strains or stresses of the different types are all mutually orthogonal (fifteen conditions). A normal system of types of reference may also be called an orthogonal system. The elements specifying, with reference to such a system, any stress or strain, will be called orthogonal components or orthogonal coordinates.

The six types described in Example (1) of Chapter XII would, clearly orthogonal, if the parallelepiped referred to is rectangular. Those three types of strain specify the strains at the centres of the edges of the parallelepiped. The remaining three are plane distortions parallel to the three pairs of opposite faces. They constitute the system of types of reference uniformly used hitherto on the theory of elasticity.

The six strains in which a spherical portion of the solid is changed into ellipsoids having the following equations:

\[
\begin{align*}
& (1) \quad 2 (x + y + z) = 1 + \xi^2 + \eta^2 + \zeta^2

& (2) \quad x + y + z = 1 + \xi^2 + \eta^2 + \zeta^2

& (3) \quad x + y + z = 1 + \xi^2 + \eta^2 + \zeta^2

& (4) \quad x + y + z = 1 + \xi^2 + \eta^2 + \zeta^2

& (5) \quad x + y + z = 1 + \xi^2 + \eta^2 + \zeta^2

& (6) \quad x + y + z = 1 + \xi^2 + \eta^2 + \zeta^2
\end{align*}
\]

are of the same kind as those considered in the preceding example, and therefore constitute a normal system of types of reference. The ratio of the magnitude of the stress to the unit of area normal to it, will be called a stress of unit magnitude, and will be reckoned as positive when it is tension, and negative when it is compression.

Each member must be equal to

\[
F^2 + \eta^2 + \xi^2
\]

when pressure in any direction is exerted, or which is the same thing, a stress component of single longitudinal strain in planes at angles of 45° to the direction of those forces, and at right angles to one another is equal to

\[
F^2 + \eta^2 + \xi^2
\]

(2) A strain component of a simple longitudinal extension, which is a strain having the ratio \( \xi = \eta = \zeta \), and is therefore identical with the number that would be produced by a single distortion.

(3) A strain component of a simple longitudinal extension, which is a strain having the ratio \( \xi = \eta = \zeta \), and is therefore identical with the number that would be produced by a single distortion.

(4) A strain component of a simple longitudinal extension, which is a strain having the ratio \( \xi = \eta = \zeta \), and is therefore identical with the number that would be produced by a single distortion.

(5) A strain component of a simple longitudinal extension, which is a strain having the ratio \( \xi = \eta = \zeta \), and is therefore identical with the number that would be produced by a single distortion.

(6) A strain component of a simple longitudinal extension, which is a strain having the ratio \( \xi = \eta = \zeta \), and is therefore identical with the number that would be produced by a single distortion.
**ELASTICITY**

Component strains, according to the orthogonal system of types described in Example 3 (1) of Chap. IX., the resultant strain equivalent to them will be one in which a square of radius 1 in the solid becomes an ellipsoid whose equation is

\[(1 - \sigma_1^2)x^2 + (1 - \sigma_2^2)y^2 + (1 - \sigma_3^2)z^2 = \sigma_1 \sigma_2 \sigma_3 - 1,
\]

and its magnitude will be

\[\sqrt{\sigma_1^2 + \sigma_2^2 + \sigma_3^2 + \sigma_1 \sigma_2 + \sigma_2 \sigma_3 + \sigma_3 \sigma_1}.
\]

(7) The specifications, according to the system of reference used in the preceding Example, of the unit strains of the six orthogonal types defined in Example 6 of Chap. IX., are as follows:

<table>
<thead>
<tr>
<th>( x )</th>
<th>( y )</th>
<th>( z )</th>
<th>( \xi )</th>
<th>( \eta )</th>
<th>( \zeta )</th>
</tr>
</thead>
<tbody>
<tr>
<td>(I)</td>

</tbody>
</table>

where \( x, m, n, r, s, \) and \( t, m', n', r' \) denote quantities fulfilling the following conditions:

\[-n^2 + \sigma_1^2 = 1, \]
\[m^2 + n^2 = \sigma_1, \]
\[n^2 + m^2 = \sigma_2, \]
\[m^2 + n^2 = \sigma_3, \]
\[m^2 + n^2 = \sigma_1 \sigma_2, \]
\[m^2 + n^2 = \sigma_1 \sigma_3, \]
\[m^2 + n^2 = \sigma_2 \sigma_3, \]
\[m^2 + n^2 = \sigma_1 \sigma_2 \sigma_3.
\]

If \( (1 - 13)X^2 + (2 - 2)Y^2 + (2 - 2)Z^2 = \sigma_1 \sigma_2 \sigma_3 - 1, \)

and

\[2X^2 + (1 - 2)YZ + (1 - 2)ZX + (1 - 2)XY = \sigma_1 \sigma_2 \sigma_3 - 1, \]

and the corresponding coefficients \( s, t, u, \) and \( v, w, x, y, z, \) are those functions transformed to \( x', y', z', d', e', f, \) and \( g, h, k, \) respectively.

The direction of any strain is specified by the values of the components \( x, y, z, \) chosen to be the directions of reference, and the stress is specified by the values of the components \( \xi, \eta, \zeta, \)

where \( x, m, n, r, s, \) and \( t, m', n', r' \) denote the concurrences of one of them with six orthogonal types of reference, and \( r, s, n, m, \) \( \) of the other.

**Cor. 7.** The most convenient specification of a type for stresses or strains, being in general a statement of the components, according to the types of reference, of a unit strain or stress of the type to be specified, becomes a statement of its concurrences with the types of reference when these are orthogonal.

**Examples.**—(1) The mutual concurrence of two simple longitudinal strains or stresses, inclined to one another at an angle \( \theta, \) is \( \cos \theta \)

(2) The mutual concurrence of two simple distortions in the same plane, whose axes are inclined at an angle \( \theta \) to one another, is \( \cos \theta \) and \( \cos (\theta - \phi) \), or \( \cos \theta \) and \( \cos (\theta + \phi) \), or \( \cos \theta \) and \( \cos (\theta - \phi) \), respectively, if \( \theta \) be the angle between the axes of elongation in the given distortion and in the first component type.

(3) The mutual concurrence of a simple longitudinal stress and a simple distortion is

\[\cos \theta \cos \phi \]

where \( \alpha \) and \( \beta \) be the angles at which the direction of the longitudinal stress is inclined to the axes of the distortion.

(4) The mutual concurrence of a simple longitudinal stress and of a uniform dilatation is

\[\sqrt{1 + \phi^2} \cos \theta \cos \phi.
\]

(5) The mutual concurrence of a simple stress or strain with reference to one system of types into \( x_1, x_2, x_3, x_4, x_5, x_6, \) with reference to another system of types, \( y_1, y_2, y_3, y_4, y_5, y_6, \) be the components, according to the original system, of a unit strain or the first type of the new system; let \( (e_1, e_2, e_3, e_4, e_5, e_6, \) be the corresponding specification of the second type of the new system, and let \( a, b, c, \) be the required transformation formula.

\[x_1 = a_1 e_1 + a_2 e_2 + a_3 e_3 + a_4 e_4 + a_5 e_5 + a_6 e_6,
\]

\[x_2 = b_1 e_1 + b_2 e_2 + b_3 e_3 + b_4 e_4 + b_5 e_5 + b_6 e_6,
\]

\[x_3 = c_1 e_1 + c_2 e_2 + c_3 e_3 + c_4 e_4 + c_5 e_5 + c_6 e_6.
\]

**Chapter XII.**—On the Transformation of Types of Reference for Stresses or Strains

To transform the specification of three strains of any type, \( x, y, z, \) of a stress or strain with reference to one system of types into \( x_1, x_2, x_3, x_4, x_5, x_6, \) with reference to another system of types, \( y_1, y_2, y_3, y_4, y_5, y_6, \) be the components, according to the original system, of a unit strain or the first type of the new system; let \( (e_1, e_2, e_3, e_4, e_5, e_6, \) be the corresponding specification of the second type of the new system, and let \( a, b, c, \) be the required transformation formula. Then we have:

\[x_1 = a_1 e_1 + a_2 e_2 + a_3 e_3 + a_4 e_4 + a_5 e_5 + a_6 e_6,
\]

\[x_2 = b_1 e_1 + b_2 e_2 + b_3 e_3 + b_4 e_4 + b_5 e_5 + b_6 e_6,
\]

\[x_3 = c_1 e_1 + c_2 e_2 + c_3 e_3 + c_4 e_4 + c_5 e_5 + c_6 e_6.
\]

**Example.**—The transforming equation is to pass from a specification (\( x, y, z, \) \( u, v, w, \)) in terms of the system of reference used in Examples (8) and (9), Chapter X., to a specification (\( x_1, y_1, z_1, u_1, v_1, w_1, \)) in terms of the new system described in Example (8) of Chap. IX., with the ordinary system, Examples (1) and (9), Chap. IX.

**Chapter XIII.**—On the Dynamical Relations between Stresses and Strains Experienced by an Elastic Solid.

**Interpretation of the Differential Equation of Energy.**

In a paper on the Thermo-elastic Properties of Matter, published in the first number of the Quarterly Mathematical Journal, April 1855, and republished in the Philosophical Magazine, 1877, second half year, it was proved, from general principles in the theory of the Transformation of Energy, that the amount of work (\( w \)) required to reduce an elastic solid, keep at a constant temperature, from one stated condition of internal strain to another depends solely on these two conditions, and not at all on the cycle of varied states through which the body may have been made to pass in effecting the change, provided always there has been no failure in

---
the elasticity under any of the strains it has experienced. Thus for a homogeneous solid homogeneously strained, it appears that $w$ is a function of six independent variables $x, y, z, t, u, \xi$ by which the condition of the solid as to strain is specified. Hence to strain the body to the infinitely small extent expressed by the variation from $(x, y, z, t, u, \xi)$ to $(x + dx, y + dy, z + dz, t + dt, u + du, \xi + d\xi)$, the work required to be done upon it is

$$\frac{\partial w}{\partial x}dx + \frac{\partial w}{\partial y}dy + \frac{\partial w}{\partial z}dz + \frac{\partial w}{\partial t}dt + \frac{\partial w}{\partial u}du + \frac{\partial w}{\partial \xi}d\xi$$

The stress which must be applied to its surface to keep the body in equilibrium in the state $(x, y, z, t, u, \xi)$ must therefore be such that it would do this amount of work if the body, under its action, were to acquire the arbitrary strain $dx, dy, dz, dt, du, d\xi$, that is, it must be the resultant of six stresses—one orthogonal to the five strains $dx, dy, dz, dt, du$, and of such a magnitude as to do the work $\frac{\partial w}{\partial x}dx + \frac{\partial w}{\partial y}dy + \frac{\partial w}{\partial z}dz + \frac{\partial w}{\partial t}dt + \frac{\partial w}{\partial u}du + \frac{\partial w}{\partial \xi}d\xi$ when the body acquires the strain $dx, dy, dz, dt, du, d\xi$, and so on.

If $a, b, c, f, g, \theta$ denote the respective components of these six stresses, with the types of reference used in the specification $(x, y, z, t, u, \xi)$ of the strains, the amount of the six stresses which fulfill those conditions will (Chapter XI) be given by the equations

$$F=ax + bx + cy + dy + ez + dz + tw + u = 0$$

and the types of these component stresses are determined by being orthogonal to the five of the strain-tensions, wanting the first, the second, \&c., respectively.

Cor. If the types of reference used in expressing the strain of the body constitute an orthogonal system, the types of the component stresses will coincide with them, and each of the components will be unity. Hence the equations of equilibrium of an elastic solid referred to six orthogonal types are simply

$$F = ax + bx + cy + dy + ez + dz + tw + u = 0$$

**Chapter XIV.—Reduction of the Potential Energy, and of the Equations of Equilibrium, of an Elastic Solid to their Simplest Forms**

If the condition of the body from which the work denoted by $w$ is reckoned to be that of equilibrium under no stress from without, and if $x, y, z, t, u, \xi$ be chosen each zero for this condition, we shall have, by Macaulay's theorem,

$$w=H_x x + H_y y + H_z z + H_t t + H_u u + H_{\xi} \xi$$

where $H_x, H_y, H_z, H_t, H_u, H_{\xi}$ denote homogeneous functions of the second order, third order, \&c., respectively. Hence $H_xdx + H_ydy + H_zdz + H_tdt + H_udu + H_{\xi}d\xi$, will each be a linear function of the strain coordinates, together with functions of higher orders derived from $H_x, H_y, H_z, H_t, H_u, H_{\xi}$. Its expression shows (section 37 above) that, within the elastic limits, the stresses are very nearly not quite proportional to the strains they are capable of experiencing, and therefore $H_x, H_y, H_z$, may be neglected, and we have simply

$$w=H_x x + H_y y + H_z z + H_t t + H_u u + H_{\xi} \xi$$

Now in general there will be twenty-one terms, with independent coefficients, in this function, but by a choice of types of reference, that is, by a linear transformation of the independent variables, we may, in an infinite variety of ways, reduce it to the form

$$w=F_{x}x + F_{y}y + F_{z}z + F_{t}t + F_{u}u + F_{\xi} \xi$$

the simplest possible form under which they can be presented.

This condition can be expressed as follows

**Prop.** An infinite number of systems of six types of strains or stresses exist in any given elastic solid such that, if a strain of any one of these is produced, the elastic reaction is balanced by a stress system of the five others of the same system.

**Chapter XV.—On the Six Principal Strains of an Elastic Solid.**

To reduce the twenty-one coefficients of the quadratic terms in the expression for the potential energy to six by a linear transforma-

...
ELASTICITY

other strain of equal amount; and the principal type to which the last corresponds is that of a strain which is manifested by a lateral shear than any other strain of equal amount in the same body. The stresses corresponding to the four other principal strain-types have each the maximum magnitude of stress, and to an amount equal to $R$, the stress required to maintain it in this state will be equal to $\pi$, where

$\Omega = (A_{\pi} + B_{\pi} + C_{\pi} + D_{\pi} + E_{\pi} + F_{\pi})$,

and will be of a type of which the concurrences with the principal types are respectively

$A_{\pi} = B_{\pi} = C_{\pi} = D_{\pi} = E_{\pi} = F_{\pi}$,

Prop. A homogeneous elastic solid, crystalline or non-crystalline, subject to magnetic force or free from magnetic force, has neither any right-handed or left-handed, nor any dipolar, properties dependent on elastic forces simply proportional to strains.

Cor. The elastic forces concerned in the luminiferous vibrations of a solid or fluid medium possessing the right- or left-handed property, whether axial or rotatory, such as quartz crystal, or tartaric acid, or solution of sugar, either depend on the heterogeneousness or on the magnitude of the strains experienced. Hence as they do not depend on the magnitude of the strains, they do depend on its heterogeneity through the portion of a medium containing a source.

Cor. There cannot possibly be any characteristic of elastic forces simply proportional to the strains in a homogeneous body, corresponding to certain peculiarities of crystalline form which have been observed,—for instance corresponding to the plagiodal faces discovered by Sir John Herschel to indicate the optical character, whether right-handed or left-handed, in different specimens of quartz crystal, or corresponding to the distinguishing characteristics of the crystals of the right-handed and left-handed tartaric acids obtained from Dr. Pasteur from racemous crystal, or corresponding to the dipolar characteristics of form and shape to have been discovered in electric crystals.

CHAPTER XVI.—Application of Conclusions to Natural Crystals.

It is easy to demonstrate that a body, homogeneous when regarded on a large scale, may be constructed to have twenty-one arbitrarily prescribed values for the coefficients in the expression for its potential energy in terms of any prescribed system of strain coordinates. This proposition was first enunciated in the paper on the Thermo-elastic Properties of Solids, published April 1855, in the Quarterly Mathematical Journal alluded to above. We may therefore subdivide the following.

Prop. A solid may be constructed to have arbitrarily prescribed values for its six Principal Elasticities and an arbitrary orthogonal system of six types, specified by fifteen independent elements, for its principal strains: for instance, five arbitrarily chosen systems of three rectangular axes, for the normal axes of five of the Principal Types; those of the sixth consequently in general distinct from all the others, and determinate, and the six times two ratios between the three stresses or strains of each type, also determinate. The fifteen equations expressing (Chap. VI.) the mutual orthogonality of the six types determine the twelve ratios for the six types, and the three quantities specifying the axes of the sixth type in the particular case here suggested: or generally the fifteen equations determine fifteen out of the thirty quantities (viz. twelve ratios and eighteen angular coordinates) specifying six Principal Types.

Cor. There is no reason for believing that natural crystals do not exist for which there are six unequal Principal Elasticities, and six distinct strain-types for which the three normal axes constitute six distinct sets of three principal rectangular axes of elasticity.

It is easy to give arbitrary illustrative examples relative to Principal Elasticities; also, to investigate the principal strain-types and the equations of elastic force referred to them or to other natural types, for a body possessing the kind of symmetry as to elastic forces that is possessed by a crystal of Iceland spar, or by a crystal of the "tesseral class," or of the included "eubel class." Such illustrations and developments, though proper for a student's text-book of the subject, are unnecessary here.

For applications of the Mathematical Theory of Elasticity to the question of the earth's rigidity and elasticity as a whole, and to the equilibrium of elastic solids in general, which are beyond the scope of the present article, the reader is referred to Thomson and Tait's Natural Philosophy, §§ 555, 740, 823, 849, and Appendix C.

CHAPTER XVII.—Plane Waves in a Homogeneous Isotropic Solid.

A plane wave in a homogeneous elastic solid is a motion in which every line of particles in a plane parallel to one fixed plane ex-
ELATERICUM, a drug consisting of a sediment deposited by the juice of the fruit of *Eclatium Elaterium*, the squiring cucumber (see vol. vi. p. 698.) To prepare it, the fruit is sliced lengthwise and slightly pressed; the gummy and slightly turbid juice thus obtained is strained and set aside; and the deposit of elaterium formed after a few hours is collected on a linen filter, rapidly drained, and dried on porous tiles at a gentle heat. Elaterium is met with in commerce in light, thin, friable, and curved opaque cakes, of a greyish-green colour, bitter taste, and teasel-like smell. The best kind is the English, prepared at Hitchin, Market Deeping, Mitcham, and elsewhere; the Maltese is generally very inferior. Elaterium is an exceedingly powerful hydrogogue and purgative, and not unfrequently produces vomiting.

Its active principal is *elaterin*, a crystallizable body of the formula $C_8H_9O_8$.

ELBA, the *Aphalea* of the Greeks, and Iva of the Romans, is an island in the Mediterranean Sea, forming part of the Italian province of Livorno, and lying about 6 miles from the mainland of Italy, from which it is separated by the channel of Piombino, and about 34 miles E. of Corsica. It has a very irregular coast outline, 18 1/2 miles long and 23 to 10 1/2 miles broad, and has a total area of nearly 90 square miles. It is throughout mountainous, and the highest point, Monte Capanee, is 2935 feet above sea-level. The western portion of the island is granitic, the eastern consists mainly of the sandstone locally known as *erroneo*, which in some places passes into a tale slate. In the vicinity of Porto Ferrajo the cliffs are cactaceous. The climate is mild, and, except at some spots on the coast, healthy. Springs are numerous, and the soil is not infertile; but agriculture and cattle-rearing are neglected, and there are no manufactures. Wine, wheat, aloe, dyer's lichen, and olives and other fruits are produced. The sardine and tunny fisheries, and the manufacture of sea-salt are of some importance; but the principal industry is mining. The iron mines are mostly in the vicinity of Rio Inferiore, and yield abundance of ore, chiefly hematite, of excellent quality. On account of the lack of fuel the ore is not smelted on the island, but is shipped direct to Follonica on the neighbouring coast of Italy, and to the port of Florence and England, A. Marble, alabaster, sulphur, and ores of tin, lead, and silver are among the other mineral products. The principal places in Elba are the chief town Porto Ferrajo, with about 5000 inhabitants, the residence of Napoleon from May 4, 1814, to February 26, 1815, Rio Ferrajo, San Petro, Porto Longone, and the village of Capoliveri. The population of the island in 1871 was 21,755.

The Argonauts, in quest of Circe are said to have loaded at Portus Aegon (Argaeum Lycaon), now Porto Ferrajo, in Elba. The island was early famous for the richness of its mines, alluded to by Virgil (Eg., x. 178). It was attacked by Phaëthon with a Syracusan fleet, 453 m. o., and subsequently by Apelles, who is stated to have sung it. In the 10th century it became a possession of Fussia, from whom it was taken by the Genoese in 1596. It fell eventually into Spanish hands, came in 1776 under the jurisdiction of Naples, and in 1801 was ceded to the king of Etruria by the Treaty of Ermens on the cession of Elba. It was united to France in 1807, restored to Napoleon by the Treaty of Paris in 1814, restored to Tuscany in the following year, and in 1860 annexed to Italy.

ELBE, the All of the Romans and the Labe of the Bohemians, a large river of Germany, with a total length of 705 miles, and a drainage area of about 55,000 square miles. It rises in Bohemia not far from the frontiers of Saxony, on the southern side of the Riesengebirge or Giants' Mountains, in $50^0 46' W$. lat. and $15^0 39' E$. long., and discharges into the Elbe at Radebeul. The numerous small streams (Seifen or Flessen, as they are named in the district) whose confluent waters compose the infant river, the most important are the Weisswasser, or White Water, and the Elbselzen; the former runs to the S.W. of the Schneekuppe in the White Meadow, and in a stone fountain in the Elbe Meadow. Augmented successively by the Adler, the Iser, the Moldau, and the Eger, it cuts its way through the Mittelgebirge of Bohemia, traverses the sandstone mountains of Saxon Switzerland, and with a general N.W. direction continues to meander through Saxony, Anhalt, and Hanover, until at length it falls into the German Ocean about $53^0 5' N.$ lat. and $8^0 50'$ E. long. The principal towns on its banks are Leitmeritz, Pirna, Dresden, Meissen, Torgau, Wittenberg, Magdeburg, Wittenbergs, Harburg, Hamburg, and Altona. A short distance above Hamburg the stream divides into a number of branches, but they all reunite before reaching the ocean. At its source the Elbe is about 4600 feet above the level of the sea; after the first 40 miles of its course it is still 698 feet; but at Dresden it is only 279, and at Arnsberg in Brandenburg only 176. At Rouge grants the width is about 100 feet, at the mouth of the Moldau about 300, at Dresden 960, and at Magdeburg over 1000. The tide is perceptible almost to Geesthacht. Of the fifty and more tributaries belonging to the system the most important are the Moldau, the Eger, the Mulde, and the Saale,—the Moldau having a course of 267 miles, the Eger of 235, the Mulde of 185, and the Saale of 229. Though the channel in some places, and especially in the estuary, is encumbered with sandbanks and shallows, the Elbe is of great importance as a means of communication, steamboats being able to ascend the main stream as far as Melnicz, and to reach Prague by means of the Moldau. Some idea of the extent of its traffic may be obtained from the statement that in 1870 at Schandau 489 passenger steamers and 2658 vessels and barges of various kinds passed up the stream, and 409 passenger steamers, 2965 ships, and 1505 rafts down the stream. By one line of canal it communicates with Lübeck, by another with Bremen, and by others with the great network of Mecklenburg and Brandenburg; and several new lines are projected, by which a direct way will be opened up to Hanover, Leipzig, and various other important cities.

For further see Dr Th. H. Schunké’s "Die Schiffahrts-Kanale im Deutschen Reich," in Petermann’s *Mittheil*, 1877.

VII. - 104
ELBERFELD, a manufacturing town of Rhenish Prussia in the government of Düsseldorf, situated in the narrow valley of the Wupper, about 19 miles E. of the town of Düsseldorf on the Berg and Mark railway. Though for the most part of modern erection, it has a large number of irregular and narrow streets, and altogether presents rather an unprepossessing appearance; the very river, polluted as it is with the refuse of dye-works and factories, rather incrasing the unsomeness. The newer quarters, however, must be excepted from this description, and many of the public buildings are large and handsome. Of these the most important are the town-house, in the modern Renaissance style, the provincial court, the exchange, the post office, the orphanage, the lunatic asylum, St Joseph's hospital, the infirmary, the Female Society's hospital, the railway company's offices, the gymnasium, and the technical school. The educational institutions include 27 popular schools where no fees are paid, and the whole system of relief for the poor is so well arranged that it has excited imitation in several towns in Germany. A great variety of textile fabrics in cotton, wool, and silk are manufactured on an extensive scale; and besides dye-works and chemical works of proportionate importance, there may be mentioned button-factories, lace-factories, a brewery, a foundry, and soap-works. The town is the seat of a considerable number of industrial, philanthropic, intellectual, and religious institutions, among which the most noticeable are the public library, the museum, and the Berg Bible Society. The inhabitants are mainly Protestants, with a strong tendency towards Pietism; but the Roman Catholics number upwards of 14,000, and the Jewish community has recently erected a new synagogue. The Elberfelder Zeitung and several other newspapers are published in the town. In 1840 the population was 31,614; in 1864, 63,300; and in 1875, 80,599.

The site of Elberfeld was marked in the 13th century by a castle belonging to the lords of Elverfeld, which was afterwards united with the Berg possessions, and held in connexion with the Low Elbe. But it was not till the fourth century that the nucleus of the present industrial development was formed by the establishment on the banks of the Wupper of the Elberfelder Verein, a manufacturing corporation in 1832. Municipal rights were granted in 1819, a great increase of the manufactories ensued in the beginning of the 19th century, silk-weaving introduced in 1765, and the dyers of Turkey red commenced in 1778. The old town was probably occupied from the end of the 14th century. It continued until the 18th century to be the scene of a considerable commerce. A suspension bridge communicates with St Aubin, and steam-boats ply regularly to Rouen. The population, which was only about 4,600 in the end of last century, amounted in 1851 to 10,238, and in 1872 to 22,563. In the quasi-suburban towns of Candehec-lès-Elbeuf, Saint-Pierre-lès-Elbeuf, and Saint Aubin-jouxe-Boulleng be included, this great industrial congeries will comprise upwards of 39,000 inhabitants.

Elbeuf, a town of France in the department of Seine-Inferieure, 13 miles S. of Rouen, on the left bank of the Seine, with a station on the railway between Oissel and Serquigny. It has three parish churches, a Protestant place of worship, a town-house with a natural history museum, a public library, a hospital, an industrial society, and a chamber of arts and sciences. The churches of St Etienne and St Jean are both of some antiquity, and preserve stained glass of the 15th and 16th centuries. The town is one of the principal seats of the woolen manufacture in France: more than half of the inhabitants are directly maintained by the staple industry, and numbers more by the auxiliary crafts. As a river-port it has a brisk trade in the produce of the surrounding district as well as in the raw materials of its manufactures. A suspension bridge communicates with St Aubin, and steam-boats ply regularly to Rouen. The population, which was only about 4,600 in the end of last century, amounted in 1851 to 10,238, and in 1872 to 22,563. In the quasi-suburban towns of Candehec-lès-Elbeuf, Saint-Pierre-lès-Elbeuf, and Saint Aubin-jouxe-Boulleng be included, this great industrial congeries will comprise upwards of 39,000 inhabitants.

Elbing, a seaport town of Prussia, at the head of a circle in the government of Danzig, 36 miles E.S.E. of the city of that name, on the Elbing, a small river which flows into the Frische Haff about four miles from the town, and is united with the Nogat or eastern arm of the Vistula by means of the Krafold canal. The old town was formerly surrounded by fortifications, but of these only a few fragments remain. There are seven Evangelical, one Roman Catholic, and two Mennonite churches, a synagogue, a gymnasium founded in 1536, with a public library of
E L C — E L D

22,000 volumes, an orphan-asylum, several hospitals, and numerous charitable institutions. Of these last a number owe their existence to the bequests of an Englishman, Richard Cowles, who settled in the town in 1810 and died at Dartmouth in 1821. The manufacturing industry is extensive and varied, producing, among the rest, many goods, iron ships, and machinery, sailcloth, woollen cloth, leather, paper, tobacco, starch, vitriol, and vinegar, and the transit trade has received a considerable increase by the opening of the Overland canal (1846–1861).

The existence of Elbing is due to a colony of Lubbeck traders who settled under the protection of the castle of the Teutonic Knights in 1237. Invited with the Lubbeck rights, and afterwards admitted into the Hanseatic confederation, the settlement was highly prosperous, and in 1335 greatly extended its limits by laying out a New Town. In 1494 it paid allegiance to Poland, and in 1544 was made the seat of a bishopric by Albert of Brandenburg, Grand Master of the Teutonic Order. After various vicissitudes, it came at last to Prussia in 1772—decadent and declining, and its present prosperity is of quite recent date. Population in 1875, 32,572.

ELCIE, a town of Spain, in the province of Alcântara, six miles from the sea, on the river Vinalap. It has three churches, as many monastic buildings, a hospital, barracks, and an old spacious palace; but there is nothing of architectural interest except perhaps the portico of Santa Maria. The costume and physiognomy of the inhabitants, the narrow streets and flat-roofed white-washed houses, and more than all the thousands of palm-trees in its gardens and fields, give the place a strikingly Oriental aspect, and render it unique among the cities of Spain. The cultivation of the palm is indeed the principal occupation, and though the dates are inferior to those of Barbary, the annual value of the crop is about £14,000. The blanched fronds are also sold in large quantities for the pneumatics of Palma and the South of Italy. For the rest, they bear the blessing of the priest, they are regarded throughout Spain as certain defences against lightning.

Eliezer is identified with the ancient Ilon or Illy of the Contestaites, which under the Romans obtained the rank of a colony with the title Itacum. In 1338 it was attacked by the Moors of Granada, who discharged against it "ruin bolts through fire" Population 18,734.

ELDAD BEN MALCHI, also surnamed Ha-Dani, Aba-Dani, Daud-Ha-Dam, or the Daimie, a Jewish traveller of the 9th century of the Christian era, chiefly interesting on account of the light (or darkness) which his writings throw on the question of the Lost Tribes. The date and place of his birth are not accurately known; but he was a native either of South Arabia or of Media. About 850 he set out with a companion to visit his Jewish brethren in Africa and Asia. Their vessel was wrecked, and they fell into the hands of cannibals, but Eldad was saved from the inhuman fate of his comrade, first by his lenience and afterwards by the opportune invasion of a neighbouring tribe. He spent four years with his new captors, was ransomed by a fellow-countryman, continued his journey as far, according to one interpretation of his story, as Chaffa, spent several years at Kairwan in Tunis, and died on a visit to Cordova in Spain. The work which goes under his name is written in Hebrew, and consists of six chapters, probably abbreviated from the original form of the narrative. It was first printed at Constantinople in 1518; and the same recension afterwards appeared at Venice in 1540 and 1605, and at Jesenitz in 1722. A Latin version by Genebrard was published at Paris in 1653, under the title of Eldad Daniebus de Judæis elationibus, or Ethique emperorum, and was afterwards incorporated in the translator's Chronographia Hebraeorum; a German version appeared at Prague in 1695, and another at Jesenitz in 1723. In 1838 M. Carmoly edited and translated a fuller recension which he had found in a MS. from the library of Eleinzer Ben Hasan, forwarded to him by Daud Zabach of Morocco. Both forms are printed by Dr. Jellinek in his Beth-IHa Medrash, vol. iv. and in. Leipzig, 1853–55. One of the most curious passages in the work is the account of the Levites, who, says the author, were miraculously guided to the land of Havila, and are there protected from their enemies by the mystic river Salbatron, which on the Salath is calm and involved in delusive mists, and on the other days of the week runs with a fierce and fordless current.

ELDER, the name of an office both in the Jewish and in the Christian church, which is used in modern times only by Presbyterians. As first applied, among the ancient Jews, for example, it had no doubt a literal fitness, indicating the responsibility and authority that natural acquire in any community to those advanced in age. As the office gradually came to be fixed in its character and limited in the number of its occupants, the name lost something of its literal fitness, the responsibility and authority becoming attached to it without regard to the age of the occupant. In this respect the kindred terms alderman, senator, etc., have had a similar history. In the Old Testament usage of the word it is impossible to fix any exact point of time at which it passed from its primary or etymological to its secondary or official sense, as the process was a gradual one, and old age continued to be regarded as the mark of the elder, as it is in modern English.

In Exodus xi. 16 elders are mentioned as a recognized official body among the Israelites, and in subsequent notices (Ex. xix. 7; Ex. xxxiv. 1; Deut. xxxi. 9) they appear as the representatives of the whole body of the people. In Numbers xii. 16, 17, seventy elders, to be chosen out of the entire body, were set apart "to bear the burden of the people" along with Moses. It is unnecessary to enter here into any discussion of the most question of the connection of this Mosaic council of seventy with large though undefined legislative and executive powers with the Sanhedrim as it existed at the time of Christ. From the time of the institution of the Mosaic council the elders are mentioned at each successive stage of Jewish history. After the settlement in Canaan they acted as the administrators of the laws in every city (Deut. xix. 11–12, xxii 3–9, 19, xxiii. 15–21) and references to them are frequent during the period of the judges and the kings, during the captivity, and after the restoration. In the New Testament the word is used to denote both an order of the Jewish economy and an office of the Christian church. Its precise significance in the latter usage is the main subject of the standing controversy between Episcopolians and Presbyterians, and a statement of the arguments on either side belongs properly to the articles on Episcopal and Presbyterian, respectively. Reference must also be made to the article on Presbytery for a full statement of the qualifications, duties, and powers of elders in a presbyterian church. It may be noted here that while the New Testament word presbyteros denotes, according to the admission of the adherents of all forms of church government, those especially set apart to the pastoral office, whatever else it may be held to include, its English equivalent elder is used as an official designation only in the presbyterian church. According to the presbyterian theory of church government there are two classes of elders, teaching elders, or those set apart specially to the pastoral office, and ruling elders, who are laymen, chosen generally by the congregation, and set apart by ordination to be associated with the pastor in the oversight and government of the church. When the word is used without any qualification, it is understood to apply to the latter class alone.
ELDER (Ang.-Sax. ellon; Gen. Holunder; Fr. sureau), the popular designation of the deciduous shrubs and trees constituting the genus Sambucus of the natural order Caprifoliaceae. The Black-berried or Common Elder, S. nigra, the bountree of Scotland, is found in Europe, the north of Africa, Western Asia, the Caucasus, and Southern Siberia, in sheltered spots it attains a height of 30 to 50 feet. The bark is smooth; the shoots are stout and angular, and the leaves glabrous, pinnate, and generally oval or elliptical. The flowers, which form corymbose cymes, with five main branches, have a cream-coloured, gamopetalous, five-lobed corolla, five stamens, and three sessile stigmas; the berries are purplish-black, globular, and three- or four-seeded, and ripen about September. The elder thrives best in moist, well-drained situations, but can be grown in a great variety of soils. It is propagated by young shoots, which after a year are fit for transplantation. It is found useful for making screen-fences in black, exposed situations, and also as a shelter for other shrubs in the outskirts of plantations. By clipping two or three times a year, it may be made close and compact in growth. The young trees furnish a brittle wood, containing much pith; the wood of old trees is white, hard, and close-grained, and polishes well, and is employed for shoemakers' pegs, combs, skewers, mathematical instruments, and turned articles. Young elder twigs deprived of leaves have from very early times been in request for making whistles, popguns, and other toys.

The elder was known to the ancients for its medicinal properties, and in England the inner bark was formerly administered as a cathartic. The flowers (Sambucus flores) contain a volatile oil, and are reputed to be diaphoretic in properties; they serve for the preparation of an emetic (sambuci emesis), and for the distillation of elder-flower water (Sambuci olusatum), used in confectionery, perfumes, and medicines. The leaves of the elder are employed to impart a green colour to fat and oil (sambuci folium et oleum suared), and the berries for making wine, a common adulterant of porter. The leaves and bark emit a sickly odour, beloved to be repugnant to insects. Christopher Gallif (Phil. Trans., 1722, lxi. p. 348) recommends that cabbages, turnips, wheat, and fruit trees, to preserve them from caterpillars, flies, and blight, should be whipped with twigs of young elder. According to German folk-lore, the hay must be doffed in the presence of the elder-tree, and in certain of the Saxon dialects of England it was believed once prevalent that the cross of Christ was made from its wood, which should therefore never be used as fuel, or treated with disrespect (see Quart Rev., xxx, 239). It was, however, a common medieval tradition, alluded to by Ben Jonson, Shakespeare, and other writers, that the elder was the tree on which Judas hanged himself; and as such it was accounted, probably to be, by the elder times accounted a disgrace. In Cymbeline (act iv. sc. 2) "the stinking elder" is mentioned as a symbol of disgrace. In Denmark the tree is sacred, and the branches must be under the protection of the "Elder-mother:" its flowers may not be gathered without her leave; its wood must not be employed for any household furniture; and a child sleeping in an elder-wood cradle would certainly be strangled by the Elder-mother.

S. nigra sylvestris is a variety of S. nigra having white bark and green-coloured berries; some ornamental varieties have blotted leaves. The Scarlet-berryed Elder, S. racemosa, is the handsomest species of its genus. It is a native of various parts of Europe, growing to 15 feet, and often producing 100 fruit. The Dwarf Elder or Danewort, S. Ebulus, a common European species, reaches a height of about 6 feet. Its cyme is hairy, by three principal branches. It is smaller than that of S. nigra; the flowers are of a dull purplish hue. All parts of the plant areathartic and emetic.

ELDON, JOHN SCOTT, BARON, and afterwards Earl of Eldon (1751–1838), lord high chancellor of England, was born at Newcastle on the 4th June 1751. His grandfather, William Scott, of Sandgate, a suburb of Newcastle, was clerk to a coal-fitter, in which service he obtained the freedom of Newcastle, became a member of the guild of Hoostmen; later in life he became a principal in the business, and attained a respectable position as a merchant in Newcastle, accumulating property worth nearly £20,000. He was twice married; his second wife, the mother of John Scott, says Lord Campbell (Lord Chancellors, vol. vii. p. 4), "was a woman of such superior understanding, that to her is traced the extraordinary talent which distinguished her two sons, William and John—Lord Stowell and Lord Eldon." It may be mentioned that William and John had each of them a twin sister.

The boys were educated at the grammar school of their native town, where, however, they scarcely gave promise of the splendid careers which they were destined to run. John Scott was not remarkable at school for application to his studies, though his wonderful memory enabled him to make good progress in them; he frequently played truant, and was whipped for it, robbed orchards, and indulged in other questionable school-boy freaks; nor did he always come out of his escapes with honour and a character for truthfulness. When John had finished his education at the grammar school, his father thought of apprenticing him to his own business, to which an elder brother Henry had already devoted himself, and it was only through the interference of William, who had already obtained a fellowship at University College, Oxford, that it was ultimately resolved that he should devote himself to the prosecution of his studies. Accordingly, on the 15th May 1766, John Scott entered University College as a commoner, with the view of entering the church, and obtaining a college living. In the year following he obtained a fellowship, graduated B.A. in 1770, and in 1771 won the prize for the English essay, the only university prize open in his time for general competition. It does not appear, however, that he distinguished himself at college any more than he had done at school by any severe application to study. It was not till after his marriage that he first concentrated his energies on the conduct of his studies. Accordingly, on the 15th November 1772, Scott, with the aid of a ladder and an old friend, carried off the lady from her father's house in the Sandhill, across the border to Blackshiel, in Scotland, where they were married. The father of the bridegroom objected not to his son's choice, but to the time he chose to marry; for it was a blight on his son's prospects, depriving him of his fellowship and his chance of church preferment. But while the bride's family refused to hold court with the pair, Mr. Scott, like a prudent man and an affectionate father, set himself to make the best of a bad matter, and received them kindly, settling on his son £2000. John returned with his wife to Oxford, and continued to hold his fellowship for what is called the year of grace given after marriage, and added to his income by acting as a private tutor. After a time Mr. Surtees was reconciled with his daughter, and made a liberal settlement on her. John Scott's year of grace closed without any college living falling vacant; and with his fellowship he gave up the church, and turned to the study of law. He became student at the Middle Temple in January 1773, and in February took his degree of M.A. at Oxford. In 1776 he was called to the bar, intending at first to establish himself as an advocate in his native town, a scheme which his early success led him to abandon, and he soon settled to the practice of his profession in London, and on the Northern Circuit. Thus, at last, had his stumbles on the high road to the chancellorship, having narrowly escaped becoming a coal-fitter, a country parson, a provincial barrister, and, according to one account, a retailer of figs and raisins.
In the autumn of the year in which he was called to the bar his father died, leaving him a legacy of £1000 over and above the £2000 previously settled on him. He was already an excellent lawyer, and succeeded fairly well on his first circuit, though not so well as to satisfy him of the safety of attempting a London career. He therefore took a house in Newcastle, with the view of establishing himself there, but still delayed to leave London; and his prospects there suddenly improving, he assigned the Newcastle house to his brother Henry. In his second year at the bar his prospects began to brighten. His brother William, who by this time held the Camden professorship of ancient history, and enjoyed an extensive acquaintance with men of eminence in London, was in a position materially to advance his interests. Among his friends was the notorious Bowes of Gisburn, to the patronage of whose house the rise of the Scott family was largely owing. Bowes having contested Newcastle and lost it, presented an election petition against the return of his opponent. Young Scott was retained as junior counsel in the case, and though he lost the petition he did not fail to improve the opportunity which it afforded for displaying his talents. This engagement, in the commencement of his second year at the bar, and the dropping in of occasional fees, must have raised his hopes; and he now abandoned the scheme of becoming a parliamentary barrister. A year or two of dull drudgery and few fees followed, and he began to be much depressed. But in 1780 we find his prospects suddenly improved, by his appearance in the case of Ackroyd v. Smithson, which became a leading case settling a rule of law, and young Scott, having lost his point in the inferior court, insisted on arguing it, on appeal, against the opinion of his clients, and carried it before Lord Thurlow, whose favourable consideration he won by his able argument. The same year Bowes again retained him in an election petition; and in the year following Scott greatly increased his reputation by his appearance as leading counsel in the Chitherson election petition. From this time his success was certain. In two years he obtained a silk gown, and was so far cured of his early modesty that he declined accepting the king's counsellorship if precedence over him were given to his junior, Mr Erskine, though the latter was the son of a peer and a most accomplished orator. He was now on the high way to fortune. His health, which had hitherto been indifferent, strengthened with the demands made upon it, his talents, his power of endurance, and his ambition all expanded together. He enjoyed a considerable practice in the northern part of his circuit, before parliamentary coroners, in matrimonial cases, and at the Chancery bar, and was in sight of the honours and emoluments of the solicitor and attorney generalships. By 1787 his practice at the Equity bar had so far increased that he was obliged to give up the eastern half of his circuit (which embraced six counties), and attend it only at Lancaster.

Shortly after taking the silk gown, he entered Parliament for Lord Wemyss's close Bordeaux of Weobley, which Lord Thurlow obtained for him without solicitation. In Parliament he gave a general and independent support to Pitt. He delivered parliamentary speeches, and was directed against Fox's India Bill. They were unsuccessful. In one he aimed at being brilliant; and becoming merely laboured and pedantic, he was covered with ridicule by Sheridan, from whom he received a lesson which he did not fail to turn to account. In 1788 Pitt conferred upon him the honour of knighthood and the office of solicitor-general; and at the close of this year he attracted attention by his speeches in support of Pitt's resolutions on the state of the king (George III, who then laboured under a mental malady) and the delegation of his authority. It is said that he drew the Regency Bill, which was introduced in 1789. In 1793 Sir John Scott was promoted to the office of attorney-general, in which it fell to him to conduct the memorable prosecutions for high treason against British sympathisers with French republicanism.—amongst others, against the celebrated Horne Tooke. These prosecutions, in most cases, were not instigated by Sir John Scott, and were the most important proceedings in which he was ever professionally engaged. He has left on record, in his Anecdote Book, a defence of his conduct in regard to them. A full account of the principal trials, and of the various legislative measures for repressing the expressions of popular opinion for which he was more or less responsible, will be found in Twiss's Public and Private Life of the Lord Chancellor Eldon, and in the Lives of the Lord Chancellors, by Lord Campbell. In 1799 the office of chief-justice of the Court of Common Pleas falling vacant, Sir John Scott's claim to it was not overlooked; and after seventeen years' service in the Lower House, he entered the House of Peers as Baron Eldon. In February 1801, the ministry of Pitt was succeeded by that of Addington, and the chief-justice now ascended the woolsack. The chancellorship was given to him professively on account of his notorious anti-Catholic zeal. From the Peace of Amiens (1801) till 1804, Lord Eldon appears to have interfered little in politics. In the latter year we find him conducting the negotiations which resulted in the despatch of Addington and the recall of Pitt to office as prime minister. Lord Eldon was continued in office as chancellor under Pitt, but the new administration was of short duration, for on the 23rd of January 1806 Pitt died, worn out with the anxieties of office, and his ministry was succeeded by a coalition, under Lord Grenville. The death of Fox, who became foreign secretary and leader of the House of Commons, soon, however, broke up the Grenville administration; and in the spring of 1807, Lord Eldon once more, under Lord Liverpool's administration, returned to the woolsack, which, from that time, he continued to occupy for about twenty years, swaying the Cabinet, and being in all but name prime minister of England. It was not till April 1827, when the premiership, vacant through the paralysis of Lord Liverpool, fell to Mr Canning, the chief advocate of Roman Catholic emancipation, that Lord Eldon, in the seventy-sixth year of his age, finally resigned the chancellorship. When, after the two abortive administrations of Canning and Goderich, it fell to the duke of Wellington to construct a Cabinet, Lord Eldon expected to be included, if not as chancellor, at least in some important office, but he was overlooked, at which he much charged, and, supporting his frequent protests that he did not covet power, but longed for retirement, we find him again, so late as 1836, within three years of his death, in hopes of office under Peel. He spoke in Parliament for the last time in July 1834.

In 1821 Lord Eldon had been created earl by George IV., whom he managed to conclude, partly, no doubt, by espousing his cause against his wife, whose advocate he had formerly been, and partly through his reputation for zeal against the Roman Catholics. In the same year, his brother William, who from 1798 had filled the office of judge of the High Court of Admiralty, was raised to the peerage under the title of Lord Stowell.

Lord Eldon's wife, his dear "Bessy," her love for whom is a beautiful feature in his life, died before him, on the 28th June 1831. By nature she was of simple character, and by habits acquired during the early portion of her husband's career almost a recluse. Two of their sons reached maturity,—John, who died in 1805, and William Henry John, who died unmarried in 1832. Lord Eldon himself survived almost all his immediate relations. His brother William died in 1836. He has
self died, in London, in his eighty-seventh year, on the 
13th January 1838, leaving behind him two daughters, 
Lady Frances Bancks and Lady Elizabeth Repton, and 
his grandson, who succeeded him. "When his remains 
lay in state in Hamilton Place," says Lord Campbell, 
"large numbers of all classes went to see the solemn 
scene; and when the funeral procession, attended by 
the carriages of the princes of the blood, many members 
of the peerage, and all the dignatures of the law, blackened 
the way, dense crowds stood uncovered, respectfully gazing 
at it as it passed." His remains were interred in the family 
vault in the chapel of Kingston, in Dorsetshire. The 
fame which he left behind him exceeded in amount half 
a million of money.

Lord Eldon was no legislator,—his one aim in politics 
was to keep in office, and maintain things as he found 
them; and almost the only laws he helped to pass were 
laws for popular coercion. For nearly forty years he 
fought against every improvement in law, or in the 
constitution,—calling God to witness, on the smallest proposal of 
reform, that he foresaw from it the downfall of his 
country. Without any political principles, properly so 
called, and without interest in or knowledge of foreign 
affairs, he maintained himself and his party in power for 
an unprecedented period by his great tact, and in virtue of 
his two great political properties,—of zeal against every 
species of reform, and zeal against the Roman Catholics. 
To pass from his political to his judicial character is to 
shift to ground on which his greatness is universally 
acknowledged. His judgments, which have received as 
much praise for their accuracy as abuse for their clumsi­ness 
and uncouthness, fill a small library. But though 
inintimately acquainted with every nook and cranny of the 
English law, he never carried his studies into foreign fields, 
from which to enrich our legal literature; and it must be 
added that against the excellence of his judgments, in too 
too many cases, must be set off the hardships, worse than 
inhumanities, that arose from his protracted delays in pronouncing 
them. A consummate judge and the narrowest of politicians, 
he was doubt on the bench and promptness itself in the 
political arena. For literature, as for art, he had no feeling. 
What intervals of leisure he enjoyed from the cares of office 
filed up with newspapers and the gossip of old cronies. 
Nor were his intimate associates men of refinement and 
taste, they were rather good fellows who quietly enjoyed a 
good bottle and a joke; he uniformly avoided encounters of 
wit with his equals. He is said to have been parsonious, 
and certainly he was quicker to receive than to reciprocate 
hospitalities; but his mean establishment and mode of life 
are explained by the retired habits of his wife, and her 
dishake of company. His manners were very winning and 
courtly, and in the circle of his immediate relatives he is 
said to have always been lovable and beloved. "He is one," says Miss Martinez, "that after times will not 
venerate; but fortunately for the fame of the larger num-
