SUMMARY

PERIOD 1866 TO 1919

The price of corn declined after the Civil War from 50 cents a bushel at the farm in 1866 to 34 cents in 1896. After that date the direction of the trend changed; it turned upward, rising more rapidly than it had previously fallen. By the outbreak of the recent World War, the price had risen to 65 cents a bushel.

During the inflation period of the World War, the price of corn rose as high as \$1.40 a bushel at the farm. Since the war, the price has fallen to about 75 cents.

If these prices are reduced to purchasing power, the movements are considerably reduced. The decline from 1866 to 1896 disappears entirely, leaving only a steady and gradual rise from 1866 to 1919. During this period the production of corn kept pace with the increasing population of livestock consuming corn. The rise in the purchasing power of corn was due mainly to the increasing purchasing power of the livestock to which the corn was fed. This, in turn, resulted from the fact that from 1866 to 1919 the demand for meat increased faster than the supply of it.

DEVELOPMENTS SINCE THE WAR

Since the war, the trend of the purchasing power of corn has fallen about 25 percent.

This lower purchasing power is not due to any increase in corn production, for production has fallen off about 5 percent. It is due to a decrease in the demand for corn and an increase in the supply of it.

In the first place, the number of horses and mules has fallen off 30 percent since the war. Cattle numbers have been reduced. The numbers of hogs on farms have also decreased, altho the numbers of hogs slaughtered have not.

In the second place, the purchasing power of hogs and beef cattle has fallen about 25 percent. This has reduced the demand for corn per head of livestock. Changes in livestock production practices have also had a similar the less important effect in reducing the demand per head.

!

Finally, improvements in corn production methods and the northwestward movement of the Corn Belt have increased the supply of corn.

PROSPECTS FOR THE FUTURE

The price of corn will be affected in the future as in the past by the movements of the general price level. The future course of this general price level is uncertain. The outlook for the purchasing power rather than the price of corn will therefore be considered.

First as to the prospective demand for corn. The number of horses and mules may be expected to continue to decrease. The trend of cattle numbers will probably be horizontal. Hog slaughter is likely to increase slowly, altho the numbers of hogs on farms are declining. The total hog demand for corn will probably continue at about its present level.

The supply of corn is likely to continue to increase, due to continued improvement in corn production methods, the northwestward spread of the Corn Belt and perhaps to decreased competition from the smaller grains.

The trend of the purchasing power of corn, therefore, is likely to move slowly downward in the future. Those who are in a position to continue to cut the cost of producing corn should be able to preserve their profits—in some cases to increase them—but those on small, rough farms may not.

APPENDIX I

In this bulletin mathematically fitted curves are used wherever advisable and free-hand curves wherever possible.

Free-hand curves are open to one or two serious objections. They are unscientific in that where they are used the work cannot be repeated with accuracy by others; no two investigators will draw in curves alike; and one is always open to the accusation, from himself if not from others, that he bent the curve a little here and there to make the work bear out whatever preconceptions he may have had, while others with different ideas might inflect the curve differently so that the work in their hands would lead to different conclusions.

The use of mathematically fitted curves is admittedly open to some of these objections also; one may reach certain conclusions, partly because he chose a certain type of curve, as easily as because he drew in a free-hand curve where he wanted it to go. But such liberties can be taken with mathematical curves only by breaking a straight line into many short sections, or by using a curved line the equation to which becomes very complicated, involving an almost prohibitive amount of labor; in either case the attempt stands convicted by its own objective characteristics.

In the case of this corn prices series, the secular movement before the war abruptly changes its direction in 1896 from downward to upward. It appears that a straight line broken at 1896 and discontinued at the war period would fit the data reasonably well. The post-war period is too short to be well represented by a trend line, but one is inserted for what it is worth.

The equations to these three consecutive trend lines, all of the type y = a + bx, are as follows:

1.	1866	to	1896,	inclusive,	y — 41.19 — .5611X
					with origin at 1881
2.	1896	to	1915,	inclusive,	y = 46.29 + 1.97X
					with origin halfway between
					1905 and 1906
3.	1922	lo	1928,	inclusive,	y — 73.79 — .1429X
					with origin at 1925

The corn production data are given in table 1 of U. S. D. A. Statistical Bulletin No. 28. The data from 1866 to 1888 have been revised slightly by Dr. O. C. Stine, in charge, Division of Statistical and Historical Research, B. A. E., U. S. D. A. As Dr. Stine stated in a letter to the author under date of April 30, 1929, "These revisions are merely mathematical adjustments to bring the figures at the end of a decade in line with the census figures. The revisions are made by distributing the difference between the estimate and the census figure back thru the previous 10 years, on the assumption of accumulative error. Acreage only was revised in this manner, the production revision being merely the revised acreage times the reported yield." These revisions "have never been published except as charted in the yearbook of 1921." They are shown in table 1 which came direct from Dr. Stine.

The equation for the unbroken trend line in fig. 2, the Secular Movements of the Purchasing Power of Corn, is:

y = 49.03 + .53x

With origin halfway between 1893 and 1894,

The trend line fitted to corn production in fig. 10 is a cubic parabola. The equation to it is:

y = 2283.81 + 1.9956 x-.4281x² -.012369x⁴

with origin at 1897

The trend lines in the rest of the charts were drawn in free-hand.

Year	Production
	(1,000 bushels)

TABLE III. UNITED STATES: CORN PRODUCTION, REVISED FIGURES 1866-1888

APPENDIX II

A later study shows that the relationship between fluctuations in the size of the corn crop and in farm purchasing power December 1 for the period 1886-1905 is 1 to 1.5. That is, a crop 10 percent larger than average results in a purchasing power 15 percent lower than average.

The influence of the large crops from 1895 to 1900, inclusive, can be removed according to the method shown in the following table. Columns A and B are taken directly from the original corn production and purchasing power series expressed as percentage fluctuations about their trend value.

Year	A Produc- tion in percent of trend	B 1.5xA	C Purchasing power in percent of trend	C and B	D Cand B+ 100	E Trend value	DxE 100 Pur- chasing power cor- rected for size of erop
1895 1896 1897 1898 1899 1990		+8.7 +40.95 +14.7 + 6.9 +14.7 +14.7 +12.75	-28.4 -36.7 -23.6 -20.7 -23.2 -16.9	$ \begin{array}{r} -19.7 \\ + 4.25 \\ - 8.9 \\ - 13.8 \\ - 8.5 \\ - 4.15 \\ \end{array} $	80.3 104.25 91.1 86.2 91.5 95.85	49,83 50,36 50,89 51,42 51,95 52,48	$\begin{array}{c} 40.01 \\ 52.50 \\ 46.36 \\ 44.32 \\ 47.53 \\ 50.30 \end{array}$

TABLE IV

The equations to the two straight lines fitted to the date thus corrected are: Period 1866-1896, y equals 42.8 + .477s, origin at 1881. Period 1896-1915, y equals 54.6 + .68x, origin halfway between 1905-1906.

APPENDIX III

The question may be asked whether there is any difference between the effect of a vertical and horizontal shift in dmand upon the market price for a good.

Fig. 12. Effect of vertical and horizontal shifts in the demand curve.

There is. This is shown most clearly if a strongly curved demand curve is considered, as in the chart (fig. 12). The original position of the demand curve is shown at D; the location of the curve after a 10 percent vertical rise is shown at D₁, and after a 10 percent horizontal move to the right, at D₂. The difference between D₁ and D₂ is considerable.

It appears that with conditions of inelastic supply, a shift in demand to the right will result in a higher price than an equal shift in demand upward. The intersection point of the supply curve S and the demand curve D₂ is higher than the intersection point with the demand curve D₁. This situation would be reversed if an elastic supply curve were used.

Apparently, a horizontal shift in demand has the same effect on price as an equal verifcal shift only if the supply curve cuts the intersection of D_2 and D_1 ; that is, if its slope is such that Δy divided by Δx equals 1.

The main reason, however, for distinguishing between vertical and horizontal shifts in the demand curve is the usefulness of the distinction as a conceptual tool in rational analysis.

APPENDIX IV

LIVESTOCK NOT ON FARMS

It is shown in the text that annual data on the numbers of livestock not on farms are not available. The figures given in the decennial census reports must therefore be used, and even they run back no farther than 1900.

Almost the only thing that can be done with this item is first to decide on a priori grounds whether the numbers of livestock not on farms bore a fairly constant relation to the numbers on farms before 1900. If they did, the next thing is to work out what that relation (proportion) has been since 1900, and then to correct the annual data showing the numbers on farms accordingly. The correction formula, if the original datum is called y, and the proportion is designated x,

$$is \bar{y} = y \frac{x + 100}{100}$$

Data for 1930 are not yet compiled, but it is safe to assume that the proportion between horses and nules not on farms and those on farms has very heavily declined since 1920 due to the advent of the motor truck and automobile in the cities. This decline was already in progress before 1920, as the reduction in numbers from 1910 to 1920 shown in table V reveals. Probably, however, the proportion remained fairly constant before 1900 since it changed little between 1900 and 1910.

The proportion between the number of hogs not on farms and those on farms fluctuated rather widely between 1900 and 1920, as table V shows; but that was probably due to the movements of the hog production cycle. The cattle proportion apparently rises steadily from 1900 to 1920. There is no way of telling, however, whether or not this is a continuation of a rise before 1900.

The whole situation is very unsatisfactory. The only redeeming features are that the proportions for hogs and cattle, which fluctuate considerably, are small (about 3 percent), so that the effect of the fluctuations is not great; while the proportion for horses and mules, which is rather high (running over 14 percent), does not fluctuate much.

The procedure that will be followed in compiling the index of demand from all livestock (on farms and not on farms) will be to multiply the annual livestock-on-farms data from 1866 to 1920 by the average

Sources of data for investock not of farms, 1910-1920: 1920 Consus Report Swine; for years 1910 and 1920, table 76, page 617 Cattle; for years 1910 and 1920, table 75, page 615 Horses and Mules; 1910 and 1920, table 74, page 615 proportion existing between it and the figures for livestock not on farms for the period 1900 to 1920 (for horses and mules, however, the average 1900 to 1910 will be used because of the marked decline in their proportion after 1910) plus 100, and dividing them by 100.

This computation, and the index figures obtained are shown in Appendix IX.

APPENDIX V

INCREASE IN CORN EXPORT DEMAND

If the purchasing power of corn had remained constant from 1866 to 1919, an increase in exports would accurately reflect an increase in export demand. The gradual decline in exports since 1877 (except for the period of big cropa and business depression in the late '90's) shown in fig. 13, would then be evidence of a gradual decline in export demand.

The purchasing power of corn, however, did not remain constant; it rose gradually from beginning to end of the period, as earlier sections have shown. From 1877 to 1918, the trend of corn purchasing power rose from 40 to 62 cents.

At the same time, as fig. 13 shows, the trend of exports declined from 70 million bushels to 50 million. Was this decline simply the result of the rise in the purchasing power of corn, the position of the export demand curve remaining unchanged, or does it represent a decline in the export demand for corn in the full schedule sense?

Figure 14 throws light on the answer. It shows the relation between annual fluctuations in corn purchasing power and exports.

Fig. 14. Exports-and-purchasing-power curve for corn.

The free-hand curve drawn thru the dots indicate that the export demand is very elastic at the lower end but only moderately so in its upper ranges.

It has been previously stated that from 1877 to 1918 the trend of corn purchasing power rose from 40 to 62 cents. This is a percentage (of the mean of 40 and 62) rise of 43.

If the corn exports and purchasing power curve had remained unchanged during this period, reference to fig. 14 shows that this 43 percent increase in the purchasing power of corn would have cut exports down two-thirds.

Actually, exports were cut only one-third, from 70 million bushels in 1877 to 50 million in 1918. The export demand for corn then must have increased 20 or 25 million bushels from 1877 to 1918.

This is only a rough approximatation, because the exports-and-purchasing-power curve based on long-time movements does not necessarily, or even probably, have the same slope as one based on annual fluctuations.

On the one hand, the exports-and-purchasing-power curve based on annual fluctuations might be expected to be more elastic than the exports-and-purchasing-power curve based on long-time changes. The surplus from an occasional bumper crop of corn would be readily taken up by European buyers who could expect to sell it at higher and more normal prices within the next year of two after they had purchased it. A persistent export surplus of corn, however, would not be so readily absorbed. It would have to be sold each year as purchased.

On the other hand, it must be remembered that in general the longer the time on which the individual exports-and-purchasing-power curve data are based, the more elastic is the curve likely to be. Buyers have more time then to adjust the uses to which their purchases are put, so as to take large quantities more easily, ie., at higher prices.

The period of bumper crops and low prices from 1895 to 1900, inclusive, seems to support the latter view rather than the former. During that period of six successive large crops and low prices, the export takings continued to be very great; the export curve remained very elastic right up to the end of the five years.

The assumption is apparently justified, then, that the long-time exports-and-purchasing-power curve should be fully as elastic as the exports-and-purchasing-power curve based on annual fluctuations.

APPENDIX VI

The rise in the purchasing power of hogs cannot be taken as a direct measure of the vertical rise in the position of the demand curve for corn.

Simply because an increase has taken place in the price of a good, it does not follow that there has been an equal vertical rise in the position of the demand curve for it. Whether a shift in the location of a demand curve, either upwards or to the right, will result in an increase in the price or in the quantity taken, or both, depends upon the conditions of supply, that is, upon the slope of the supply curve.

If in this case the number of bushels of corn fed per hog remained substantially unchanged over this whole period and the total numbers of livestock also kept pace with the growth of total corn production, the conclusion would be that the vertical rise in the position of the demand curve was roughly as great as the rise in the marginal cost of production for the larger quantity of corn being produced,

If, however, the number of bushels fed per hog increased, then the vertical rise in the location of the hog-demand curve for corn must have been greater than the rise in the marginal costs of producing the larger production of corn.

This second situation appears to be what actually happened: because. as pointed out in a later section, the consumption of corn per head increased to some extent in the later part of the period.

The conclusion is, then, that a somewhat greater vertical rise took place in the demand curve for corn than is indicated by the increase in the purchasing power of hogs thruout this period.

APPENDIX VII

The changes in the small items have been slight.

The first item is the exports. In the period just before the war they amounted to 1.5 percent of the total crop. After the war they fell off; the simple average of the exports from the United States for the last four years, 1923-1927 inclusive, is 0.7 percent of the total crop. The reduction in exports therefore accounts for only 0.8 percent of the total production of corn."

The amounts taken by merchant mills have decreased. The data are shown in table VI.

*Preliminary report. *Tables VI, VII and VIII are taken from pp. 80 and 81 of U. S. D. A. Statistical ulletin No. 28, "Corn Statistics," 1928, prepared by the Bureau of Agricultural Bulletin No. 28, "Corn Stat Economics, Washington, D. C.

"It could at the most have accounted for only 1.5 percent of the total production of "It could at the most nave accounted for only 1.5 percent of the total production of court, since this is all that was exported on the average just before the war. Yet it must be remembered that actually the reduction in the export demand must have been very great. Otherwise the 25 percent reduction in the purchasing power of corn after the war would have resulted in greatly increased exports, instead of the slight decrease that actually occurred; for fig. 14 in Appendix V shows that the export de-mand for corn is shalle, specially in the lower part of the curve. See also the dis-tunion is a houseding V. cussion in Appendix V.

The table shows that since 1920 there has been a reduction of about 30 million bushels in the amount of corn taken by merchant mills. Other industrial uses take only small amounts of corn. The changes in these items are negligible, as tables VII and VIII show.

Compiled from monthly reports of the Survey of Current Business, United States Department of Commerce. Grindings of corn by the wet process in the manufacture of cornstarch, glucose, etc., as compiled by the Associated Corn Products Manufacturers from reports of manu facturers.

These tables show that there has been a decrease in the quantity used for alcohol and other spirits; but this has been more than offset by the 30 or 40 million bushel increase in the grindings by cornstarch and glucose mills.

It must be remembered, however, that this does not show that the total industrial demand for corn remained unchanged. The amounts taken remained roughly unchanged, but this was in the face of a reduction in the purchasing power of corn. The total industrial demand for corn then must have decreased considerably since 1920.

APPENDIX VIII

There are several reasons for the lack of agreement between the numbers of hogs on farms and total hogs slaughtered.

In the first place, with the passage of time a larger proportion of total hog slaughter has been coming under federal inspection. The proportion grew from 48 percent in 1900 to about 66 percent in 1925. Most of the increase in this proportion, however, took place before 1920. A more important change since 1920 is the shifts that have occurred in the geographical distribution of hog production. "Rather significant changes took place in the geographical distribution of hogs between 1920 and 1925 and very slight changes between 1925 and 1929. In 1920 about 37 percent of the hogs in the United States were in the West North-Central states; in 1925 the proportion had increased to 50 percent. In 1920, 31 percent of the hogs of the country were in the South Atlantic and South Central states; in 1925 only 20 percent. Changes in other sections were small, altho there was a tendency for production in both the North-Atlantic and East North-Central states to decline in relative importance. This tendency toward concentration, which has brought half of the hogs in the country into the West North-Central states, where hog production is conducted rather efficiently, accounts for a part of the increase in the output of pork."⁴

An additional effect of these geographical shifts is that it has brought hogs into the area in which the highest proportion of total hog slaughter comes under federal inspected slaughter. This would increase the proportion of federal inspected slaughter to total slaughter.

Furthermore, improvement has taken place in the technique of hog production.

"Apparently the campaign for more sanitary methods of production, which has resulted in appreciably larger litters of pigs saved and reduced the losses from cholera and other diseases,—and the use of better animals" are enabling a given hog population on farms to produce more hogs for market now than formerly.

Finally, either one or both of the two series may be revised in the light of the 1930 census figures. Such a revision might lessen the disparity between the two series.

APPENDIX IX

CHANGES IN UNITED STATES DOMESTIC DEMAND FOR CORN DUE TO LIVESTOCK AND OTHER POPULATION CHANGES

1867-1930

(000's omitted)

DATE	A No. of hogs on farms & else- where* (No. on farms x 1.032)	B Estima- ted hog consump- tion of corn*** (Ax19.7)	C No. of horses & mules on farms & elsewhere (No. on farms x 1.145)	D Estimated horse & mule con- sumption of corn (Cr22.3)	E No. of cattle on farms & else- where (No. on) farms x 1.029)	F Estimated cattle con- sumption of corn (Ex6.6)	G No. of poultry on farms Jan. lat	H Estimated poultry consump- tion of corn (Gx0.33)	I U.S. human popula- tion	J Estimated human consump- tion of corn (1x0.37)	K No. of sheep on farms	L Estima- ted sheep consump tion of corn (Kx0.81)	TOTAL of B.D.F. H. J. and L.

Livestock dats from U. S. D. A. Yearbooks; human population data from cansus resorts. •Numbers on farms multiplied by a factor to include those not on farms. Factor given in Appendix, "Livestock not on farms." •Numbers of hogs multiplied by 10.7, the estimated consumption per head. The figure 19.7 is derived by dividing 40 percent of United States average corn production 1912-1921 by the average number of hogs for the same period.

The livestock figures from 1890 to 1899 show a marked downward movement followed by a jump from 1899 to 1900, the census year. One-tenth of this 1899-1900 difference in these data in the last column has therefore been added cumulatively to the 1890-1899 figures.
